VAN DIEMEN'S LAND, or TASMANIA. This island as long considered to form the southern termination f the great island of New Holland; and it was only as- ertained to be an island in 1798, by Surgeon Bass and ieutenant Flinders. It is situated between the paral- els of 41° 20′ and 43° 40′ S., and the meridians of 144° 40′ and 148° 20′ E. It is of an irregular shape, somewhat in the form of a heart, its broadest part toward the north. Its greatest extent from north to south is estimated at about 210 miles, and from east to west 150 miles. It is nearly about the size of Ireland, covering an area of about 24,000 square miles. This country was first discovered by Tasman in 1642. In 1773 it was visited by Captain Furneaux, and by Captain Cook in 1777, since which period it has been visited by different navigators. Among others, Bruny d'Entrecasteaux made this coast in 1792, and afterwards revisited it in 1793. He entered a channel, which he spent some time in exploring, and which is since known by the name of D'Entrecasteaux's channel. These discoveries were further prosecuted by subsequent navigators, and particularly by Lieutenants Bass and Flinders, who, in different voyages, in which they were occupied from 1795 to 1803, made a complete survey of this coast, and also a great part of the coast of New Holland.

In 1803, a detachment of troops under Lieutenant Bowen arrived here from Sydney, for the purpose of establishing a penal settlement; but nothing appears to have been effected at that time beyond the selection of a spot for that purpose. Early in 1804, Lieutenant-Governor Collins, having in view a settlement on the southern coast of New Holland, arrived from England with a more considerable expedition; and having altered his determination, he directed his course to the river Derwent, when the island was formally taken possession of in the name of his Britannic Majesty. After various surveys of the Derwent, the present site of Hobart-Town was decided upon for head-quarters. Besides several individuals of respectability, he had with him about 400 pensioners, with about fifty prisoners. The colony being thus planted, continued to take root, although at times suffering great hardship. For the first three years the inhabitants were wholly dependent on foreign supplies of food, and were occasionally reduced to great straits, insomuch that kangaroo meat was purchased at 1s. 6d. per lb., and sea-weed, or any other vegetable substance fit for food, likewise at a high price. About this time sheep and cattle began first to be imported into the colony; and fresh arrivals of prisoners increased the population, which still preserved the character of a penal settlement for convicted felons. In 1810 Governor Collins died, and was succeeded by his second in command, and by other three provisional governors. In 1813 Lieutenant-Colonel Davey arrived from England as lieutenant-governor; and about this period the rising importance of the colony began to be gradually developed, and its prosperity was greatly favoured by its port, from which hitherto all merchant vessels, except those from England and New South Wales, had been interdicted, being declared free to the ships of all nations. This wise and necessary measure was followed by the most beneficial effects; trade began to improve, its surplus produce was freely exported, and such returns were received as were calculated greatly to increase the wealth of the colony. Society began to assume the appearance of civilization; and although the stream of emigration from home had not begun to flow in this direction, yet the officers of the different regiments which had been stationed in the colony, and so remained in it, with the settlers brought from Norfolk Island on its evacuation, besides occasional arrivals from New South Wales, and emancipated convicts, formed a considerable addition to the population. A greater quantity of land was cultivated, houses multiplied in different quarters, farms were inclosed, and symptoms of growing wealth and prosperity began daily to appear. Colonel Davey's administration lasted till the year 1817. He was succeeded by Colonel Sorell, who was intent on the internal improvement of the colony, and who directed the formation of new roads, the erection of bridges, and the establishment of schools and other institutions. In 1821 emigrants began to resort in great numbers to this country; and as they brought with them an increase of capital, cultivation was rapidly extended on all sides. A regular trade was begun, distilleries and breweries were erected, the Van Diemen's bank was established, St. David's church at Hobart-Town was completed, and every thing now indicated the rapid progress of this rising community. According to a census taken in 1821, the inhabitants were found to amount to 7185; the acres in cultivation to 14,940; sheep, to 170,000; cattle, 35,000; and horses, 350. The colony was still dependent on New South Wales, and had no regular civil or criminal courts, occasional sessions being only held by judges who arrived from New South Wales. In 1825 this defect was remedied: Van Diemen's Land was declared by the king in council independent of the colony of New South Wales; the chief authority was vested in a lieutenant-governor and council, the latter consisting, according to the 9th Geo. IV. c. 83, of fifteen members; civil and criminal courts were established; and the sole dependency of the colony was in future on the mother country.

The prosperity of the colony was long retarded, and the lives and properties of the inhabitants endangered by a banditti of runaway convicts, who took shelter in the woods, and issued in bands from these hiding-places, to plunder the settlements and to murder their proprietors. They were known under the title of bush-rangers; and they even proceeded so far as to write threatening letters to the magistracy and the lieutenant-governor. A feeling of insecurity pervaded the more remote settlements; and the most respectable farmers, with one accord, betook themselves to the towns as the only certain refuge from the violence of these wretches, who scrupled not at conflagration, robbery, and murder. They long continued their depredations with impunity, owing to the insufficiency of the military force, the ample subsistence afforded by the abundance of game, and the superior local knowledge which they acquired in the course of their wandering life. In order to abate this growing evil, Colonel Davey proclaimed the whole island under martial law; and the military being seconded by the respectable inhabitants, succeeded in apprehending the most daring of these offenders, who were executed and hung in chains as a terror to their associates. The proclamation of a general amnesty induced others to surrender. But many of these again escaped into the woods, and renewed their lawless outrages against the persons and properties of the settlers; and it was not till the year 1817, that, by great exertions of the troops, aided by the settlers, this gang of banditti was rooted out, most of them being apprehended by the activity of the troops, and executed.

Aspect of the country.

Van Diemen's Land, seen from the coast, has a more agreeable aspect than New Holland. Many fine tracks of land are found on the very borders of the sea; and the interior is almost invariably possessed of a soil admirably adapted to all the purposes of civilized man. The island is upon the whole decidedly mountainous. In the interior it is extremely diversified in its surface; not so much, however, by continuous ranges of mountains, as by insulated peaks, with intervening tracks of table land, and extensive and fertile valleys. On the south of the island, the country presents a peculiarly bold and rude aspect, hills being piled upon hills, all densely covered with trees to the top, and presenting one impervious forest, except here and there a rocky eminence towering to a majestic height. Farther inward the country assumes a less stern and forbidding aspect, and many fine open spots meet the eye, lightly timbered and extending for miles; the prospect, however, being still closed by a background of lofty mountains. Between Hobart-Town and Launceston, towards the north, there is a fine champaign country intersected by streams, and of great extent; and towards the north coast the scenery consists of every variety of hill and dale, woodland and plain, forest and village, that forms the perfection of a rural landscape. The western parts of the island, though they have been imperfectly explored, are represented as abounding in bold and mountainous scenery, although possessing well watered and fertile plains. Here the ground generally rises to a great elevation, and has consequently a milder climate in winter than the inhabited districts towards the east. Of the mountains there are several which rise to a great height. Mount Wellington, which is only a few miles west from Hobart-Town, is 4000 feet above the level of the sea. It has a magnificent appearance; and its bold and rugged hills are diversified with occasional spots of sombre foliage. During eight months of the year it is covered with snow; but so pure is the atmosphere, that its summit is seldom obscured with clouds. Being so near Hobart-Town it has frequent visitors in summer. The southern mountains near Port Davey form a long range, which stretches into the interior for several miles, and in some places rises 5000 feet above the sea. They are covered with snow during the greater part of the year. The other principal mountains in the colony are Benlomond, distant about 100 miles from Hobart-Town, and rising 4200 feet; the Table mountains near Jericho, 3800 feet; Peak of Teneriffe, or Wylede's Craig, 4500; Quamby's Bluff, 3500; Mount Field, 3000; St. Paul's Dome, 2500; with several others, from 1000 to 2000 feet in elevation.

The country is well watered, numerous streams flowing from the mountains; and on the summits of many of them are large lakes, which are the sources of considerable rivers. The Derwent is a noble and magnificent stream, varying in breadth, from its entrance up to Hobart-Town, from six to twelve miles, having everywhere deep water, without rocks or sand-banks, and navigable at all seasons, even by strangers, with the most perfect ease and safety. The mouth of the Derwent is formed on the right by Bruné island and D'Entrecasteaux's channel, and on the left by Iron Pot island and the South Arm; the latter presenting for six miles a coast of highly luxuriant appearance, and then abruptly terminating in the centre of the Derwent, where the river, uniting with the waters of Double Bay, extends its width to nearly twelve miles. This river takes its rise in a lake to the westward, and flows with considerable rapidity, receiving numerous tributary streams until it reaches New Norfolk, where it is almost as wide as the Thames at Battersea, whence it pursues its course towards the ocean, widening as it goes, with the finest scenery on its banks. The water continues fresh for about six miles below New Norfolk. The Huon is nearly of equal magnitude with the Derwent, and runs westerly until it falls into the sea in one of its arms or creeks not many miles from Hobart-Town. Though it be a navigable river, it is however of little value to the colony, the land on its banks being so heavily timbered, that it is neither arable nor fit for pasturage. It is occasionally resorted to by vessels of considerable burden for the timber on its shores, which is taken in as ballast. The Tamar, formed by two rivers, the North and South Esk, is navigable for its whole course, though, on account of a bar and other intricacies of navigation, it requires great skill and management on the part of the pilot to take up or down large vessels with safety. Among the rivers of the second class that water fine districts, and are extremely useful, though they are not navigable, may be enumerated the Shannon, the Clyde, and the Jordan, all of which fall into the Derwent, either singly, or having previously united above New Norfolk; the Coal river, which falls into the sea near Richmond; and the two Esks, which join and form the Tamar at Launceston. There is still a numerous class of smaller rivers, which have an abundant supply of water all the year round for mills, cattle, and dostic use. There are the Thames or Lachlan at New orfolk; the Plenty, the Styx, Jones's river, and Russell's f s, which are also tributaries of the Derwent; the Mac- arrie and Elizabeth rivers, more in the interior, and ich are tributaries of the Esk; Blackman's river, also i the heart of the colony. Farther north is the Lake r er passing through Norfolk plains, the Western river, t Isis, and several others of less note. More to the w stward are the Mersey, the Meander, the Forth, the Iris, t Leven, the Emu, the Cam, the Inglis, and numerous o ers, which are spread over all parts of the colony. A ound the coast of the island many streams fall into the o an, having spread fertility over the districts through w ch they have previously flowed. Among these may be m tioned the Carlton, Prosser's river, Great Swan Port ri r, Piper's river, &c.; also North-west Bay river, a fe miles from Hobart-Town. Others again are found in d ert situations in the country, where cultivation has made li e progress. There are several lakes, generally in the c tre of the island among the mountains, of considerable e ent, which abound with water-fowl of all descriptions. G at Lake is about ninety miles north-west of Hobart-T vn, and eighty feet above the level of the sea. It is tv nty miles long and ten broad, with deep bays and in- d tations, and many promontories and peninsulas extending in it. It contains five islands, covered with a species of c ar, and numerous shrubs. Its greatest depth is only th e fathoms. Around the coast are numerous bays and h bours that afford secure anchorage. The entrance from th ocean to the Derwent presents two lines of continuous b s or anchorage of unrivalled excellence. The one most co monly used leads through Storm bay, and the other th ugh D'Entrecasteaux's channel, which is one string of lit e bays or anchorages for nearly forty miles. On the ea ern coast of the island is Oyster bay and Great Swan P t; on the north, Port Dalrymple, or the mouth of the T nar, Port Sorell, and Circular Head; westward, Mac- qu rie harbour and Port Davey. Besides, there are many of naller note, capable of affording secure shelter to craft of ight burden.

he climate of this island is equally healthy, and more co genial to the constitution of Europeans, than that of Port Ja son, not being subject to any remarkable variations ei er of heat or cold. Generally speaking, throughout the su mer, alternate land and sea-breezes prevail every twenty-fo hours; the wind blowing from the land from sun-set til en or eleven o'clock the following day, when it is suc- ce led by the sea-breeze, which continues till the evening. It influence extends many miles inshore, and diffuses a freshing coolness, even in the hottest days of sum- m . The average thermometer is 70°, although the heat is casionally much greater, the mercury rising to 100° or 11 . This sudden heat is occasioned by the north and no h-west wind, which is felt at Port Jackson, and here, th gh not in the same degree, though its effects are seen on e growing crops, producing blight and other injurious co equences. The rain which is almost certain to suc- ce in a few hours, again cools the atmosphere, and corrects th ad effects of the previous sultriness. Thunder-storms ar are, nor are they ever violent. During spring, which is the months of September, October, and November, the we her is usually bright and clear, with occasional rain and hi winds; when the average range of the thermometer is be een fifty and sixty degrees. The summer, which is in D ember, January, and February, is generally dry; during w h the vegetable productions arrive at maturity one m th earlier than they would in England, namely, in De- ce ber, which corresponds to June of the northern hemi- sp re. Autumn, which is in March, April, and May, is th pleasantest season in the year; the air being clear and br ht, free from clouds and vapours, and the medium heat of the day about 65°. The nights are cool and refreshing, which indeed is generally the case in the height of summer. The winter, which is in June, July, and August, is not severe. In the high and exposed situations, the snow falls thick, and lies a good part of the year, and the frosts are severe; but in the lower valleys and plains, the sun never loses its power during the day, and under its influence, frost and snow quickly disappear; so that the winter is not regarded by the inhabitants as the cold and dismal period of the higher latitudes, but as the season of moderate and genial rain, which facilitates the labours of the husbandman in the ensuing spring. The average range of the thermometer is from forty to forty-eight degrees, though sometimes it falls lower, but seldom continues above a day or two.

Van Diemen's Land

Soil and productions.

Van Diemen's Land abounds in every variety of soil, and with much less of an indifferent quality than is to be found in New Holland. Large tracks of land, perfectly free from timber or underwood, are to be found in all directions, and covered with luxuriant herbage; where the colonist, entering on the possession of the best land, incurs no expense in clearing his farm, but has only to set fire to the grass, in order to prepare his land for immediate tillage. There are other two circumstances which are extremely favourable to the colonist. The rivers have all a sufficient fall to prevent any excessive accumulation of water from heavy and continued rains, and are consequently free from those violent and destructive inundations to which the rivers of New Holland are subject; and here the colonist may settle securely without the dread of having his lands submerged and his produce swept away by the devouring flood. The seasons are more regular, and not liable to the same inequalities, and to those periodical droughts by which New Holland is visited. In the years 1813, 1814, 1815, and likewise in 1839, when the whole face of the other colony was burnt up, when vegetation was completely at a stand, and the cattle were perishing for want of rain, there were abundant harvests in this more fruitful island, and no want of rains. Within a period of about forty years since the country was settled, the crops have sustained no serious detriment from the want of rain, and the harvests have in general been productive; while the parent colony, since it has been established, has been repeatedly in the greatest distress from dearth and from inundation. The agricultural products, with some differences arising from the climate, are nearly the same as at Port Jackson. Indian corn or maize is not cultivated here; but wheat, barley, and oats are raised of a very superior quality. Nor is there such a variety or abundance of fruit; the finer fruits of those latitudes that are nearer the equator, such as the orange, the lemon, the citron, the pomegranate, &c., which grow in the greatest perfection at Port Jackson, are not known in this island, while the peach, the nectarine, and the grape arrive at an inferior degree of maturity, and can only be raised by artificial means. But on the other hand, all the fruits, such as the apple, the currant, the gooseberry, and all vegetables and herbs that grow in the northern climate of Europe, thrive equally well in this congenial climate. The vegetable kingdom is similar to that in New South Wales. The forests abound in woods that are adapted to all the various purposes of life. In many places there is no underwood, the ground being covered with tall ungainly trees, standing at some distance from each other, and rising up to a great height, before they shoot out their branches. Much of the timber is extremely serviceable for the purpose of building; while there are ornamental woods, which are highly esteemed for cabinet work, and for fitting up and embellishing the interior of houses; and others for their hardness and durability. All the trees are evergreens, and some of them, particularly the mimosas, put forth very rich blossoms in spring. But the colour has been remarked to partake more or less of yellow. The foliage of the trees is generally dark green, which gives rather a sombre aspect to the forests; the eye wandering over the wide expanse every where presented, and in vain seeking relief from any variety of hue. There is a great variety of shrubs, many of which are extremely beautiful, and some of them have very elegant flowers. Among the most valuable plants yet discovered, may be classed the pepper tree, the trunk of which contains many medicinal properties. The tea tree is also deserving of notice, the leaves serving at times as a substitute for those of the Chinese plant, and though the beverage is not equally good, it has the recommendation of being much cheaper.

Minerals. The island has not yet been sufficiently explored for the discovery of its mineral treasures. Its geology is very varied. Basalt is however supposed to be the principal substratum of the soil, and all along the coast it presents itself in rocky precipitous heights, standing on beautiful columnar pedestals. Among these may be mentioned Fluted Cape at Adventure Bay. It is so called from the circular columns standing up close together, in the form of the barrels of an organ. Circular Head is another singular specimen of the basaltic formation. It is a curious rock, standing out of the sea, exactly like a huge round tower or fortress, the work of art. Mount Wellington, already mentioned, is composed of this rock, as well as the rocky banks of many of the mountain rivers. In some parts, both on the coast and in the interior, the columns appear in insulated positions, springing up from the grass or the ocean like obelisks or huge needles. There are several specimens of this curious formation on the south side of Bruné island; and the rocks on the land stand erect upon their several blocks, gradually diminishing as they rise, so that the force of a well-aimed stone would seem sufficient to drive the uppermost from its precarious base. Limestone is almost the only mineral that has been brought into general use. It has been found in abundance in most parts of the island; and a very fine species of lime, used in the better sort of plastering and stuccoing, is made in considerable quantities, by burning the oyster shells that are found in beds along various parts of the coast. Other calcareous substances occur in different parts of the island. Marble of a white mixed grey colour, susceptible of a good polish, has frequently been found. Around Hobart-Town, strata of soft clayey marl occur, which has been found very useful as a manure. Much of the common limestone is of a yellowish or reddish colour, derived from the oxide of iron with which it is mixed, and which is so generally scattered throughout the island. Of the metallic ores, that of iron abounds, of a red, brown, and black colour. In one or two instances in which it has been analyzed, it has been found to contain eighty per cent. of the pure mineral. It also occurs, though more rarely, and in smaller quantities, under the form of red chalk. Specimens of red and green copper ore, lead, zinc, manganese, and, as some say, silver and gold, have been occasionally met with. Indications of coal have been found all across the island, commencing at South Cape, and shewing themselves in various parts; at Satellite island in D'Entrecasteaux's channel, on the banks of the Huon, at Hobart-Town, New Norfolk, the Coal river, Jerusalem, Jericho; and excellent coal and very rich iron ore have also been discovered in Richmond district and other places. The stratum of the South Cape is situated on the north side of the bay, and extends almost two miles along the coast. This coal has been analyzed, and has been found of a superior quality, and well adapted for the raising of steam. Excellent roof slate appears at a certain spot between Launceston and George-Town; and in the form of mica in large masses on the rocks round Port Davey, on the southern corner of the island, where, being much exposed to the winds and waves of the southern ocean, they have become so much worn by the weather as to exhibit the appearance of snow. Excellent sandstone for building is found in almost every part of the island, and most of the houses in Hobart-Town are now built with it, instead of badly made bricks as formerly. A m quarry has also been recently discovered at Port Arthur, where the manufacture of filtering-stones is expected to be commenced. Flints are scattered in great plenty upon the hills, especially where basalt abounds. Other rarer stones have been found in different parts of the island, especially in those which appear to have been washed in former times by the ocean, and which have been deposited in certain ranges or linear positions, by the lashing of the waves and the subsiding of the waters; such as hornstone, schistus, wood-opal, bloodstone, jasper, and that other singular species called the cat's eye, which reflects different rays of light according to its position. Petrified remains of wood and other vegetable productions, entirely converted into siliceous matter, and capable of the finest polish, are occasionally met with in different parts of the island, especially in the Macquarrie district.

The animals resemble those of New South Wales, comprising the kangaroo, of which there are three different species, the forest, the brush, and the wallapy, the chier difference between them being the size. The hyena, opossum, or tiger, measures six feet from the snout to the tail, and is exceedingly destructive among the flocks. It is beautifully striped with black and white on the back, and the belly and sides are of a grey colour. The *dasyurus ursinus*, known by the ordinary name of the devil, is another animal of the same species, extremely ugly, the head resembling that of the otter, but quite disproportionate to its body. It is very destructive to the flocks, issuing at night from the rocky hills which it frequents, in search of its prey. The native porcupine resembles the common hedgehog, and is quite harmless. The wombat is a singular animal, and when full grown weighs nearly forty-three pounds. The head, which is large and flattish, forms an equilateral triangle. It has extremely short legs, ears sharp and erect, eyes small and sunken, but lively, and the feet are formed like those of a badger; the tail is an inch in length. The flesh is very delicate. The *platypus* is an animal apparently allied to the beaver tribe. The body is about ten inches long, and about as many in circumference. This animal is very shy, and is only found in unfrequented places. Several species of wild cats are found in the woods. One is called the tiger-cat, from its resemblance to that animal; others partake of the character of the weasel. The kangaroo rat and the kangaroo mouse possess, with the size of these animals, all the characteristics of the kangaroo. There are several species of opossums, all perfectly harmless. The bandicoot is a small animal, which makes great havoc in the potato grounds when it visits them.

The feathered tribes are numerous, of every description, and many of them of the most beautiful plumage. Among the birds of prey are eagles, hawks of all sorts, kites, ravens and the common carrion-crow. Among the water-fowl are many varieties of the gull, pelican, the kingfisher, black swans of very majestic appearance, wild ducks, also the musk duck, teal, widgeon, and a variety of others. Among that class which belong neither to birds of prey nor t water-fowl, are emus, black and white and satin cockatoos parrots and parroquets in great variety, large black magpies, the white or the whistling magpie, the laughing jackass, so called from its singular noise; with many other of smaller size, but of more beautiful appearance. Quails snipes, and a species of pigeon of a splendid bronze colou in flavour resembling a partridge, are the chief birds tha in addition to water-fowl, attract the attention of sportsmen

All the inlets and bays of the coast abound with fish Among those which may be purchased at Hobart-Town, ar the salmon, so called in the colony, but in reality a very poo fish; perch, rock-cod, bream, mullet, whitings, flat-heart leather-jackets, tailors, parrots, guard-fish, cray-fish, nea

Die- Land

as good as lobsters, oysters, good and plentiful, eels, ate, and shrimps. Some years ago mackarel, of a very nall species, were caught, but they have since disappeared. lack-fish are plentiful in the Mersey, and generally weigh om five to fifteen pounds; they have no scales. The inrior rivers and lakes abound with very fine eels, but, expt the mullet, they are of little value. The toad-fish, und in the bays and shores of the island, is a strong poison. his poison is of a powerful sedative nature, producing stupor, d acting on the nervous system. The black whale rerts during the breeding season to the deep estuaries of vers, and to the bays and inlets around the island. This hery is pursued with great activity and success. There e several kinds of snakes, some of them poisonous; the ost common one a large black snake, the diamond ake, and a smaller brown sort. In the reptile family may classed the guanas and lizards, said to be harmless; cenpedes of two sorts, scorpions and tarantulas, the latter ten met with in rotten wood. There are many curious d beautiful varieties of the beetle; three or four sorts, me of which are an inch long, and sting sharply. The ld bee is found, and a variety of spiders. All the domes- animals of Europe thrive, and increase in size.

tion

The population here, as in New South Wales, consists three classes, the aborigines, the convicts, and the free habitants. The aborigines, or blacks, more resemble in eir countenance and appearance the African negro than ose of New South Wales, though living under a colder mate. Their hair is woolly and their complexion black, and ey are said to be inferior in ingenuity, as well as in muslar strength. For several years an inveterate hostility preiled between them and the civilized inhabitants; and the fenceless farmers and stock-keepers were often murdered the natives. These outrages at last roused the spirit the whole country; and the troops, and all those that re capable of bearing arms, formed a cordon round the origines, with the intention of confining them in the ninsula called Tasman's Head, where all their wants were be supplied, and an attempt was to be made to civilize em. They however broke through this cordon like so ny wild beasts; but by the humane exertions of some the settlers, aided by a few of the more civilized aborines of Sydney, they have been removed to Flinders Island, Bass's straits, where they are clothed and fed, and attempts made to civilize them. Their number does not exceed 300, d, as usually happens with savages when they are brought thin the bounds of civilization, they are gradually decaying.

The convicts amount to 12,000. Every convict who is nsported to Van Diemen's Land, without any reference previous circumstances, is either placed in the public vice or is assigned to individuals immediately on landing. e first are compelled to devote their whole time to the vice of the crown, and receive in return food, lodging, d clothes. Labourers and mechanics reside in barracks ilt for the purpose; clerks employed in the public offices permitted to live elsewhere, and receive a small pittance; se who are assigned to individuals are still under the sest surveillance, and can go nowhere without a pass. e convict prisoners are divided into classes: 1. Such ourers or mechanics as, on account of especial good conct, are permitted to sleep out of the barracks, and to work themselves the whole of each Saturday. 2. Those o still lodge in the barracks, but who are allowed to work themselves the whole of each Saturday. 3. Those o are employed on the public works, and are released m work every Saturday at noon. 4. Refractory or disderly characters, worked in irons for crimes committed the country, under a sentence of the magistrate. 5. Men the most degraded and incorrigible character, worked in ns under the sentence of a magistrate, and kept entirely separate from the other prisoners. 6. Men removed for crimes to penal settlements, which are distant stations under the governments of New South Wales and Van Diemen's Land, where none but prisoners and their guards are allowed to remain, and where the former are kept to unremitting labour. The rewards to prisoners for good conduct consist of tickets of leave, which exempt the holder from compulsory labour, and emancipations, which restore freedom, but without permission to leave the country.

Van Diemen's Land

The free population ranges between 15,000 and 20,000. The following is an account of the population from a recent census:—Free persons, 20,886; convict ditto, 11,938; Port Arthur, 1137; Flinders' Island (black and white), 183; other islands, 50; military (with wives, &c.), 1054. Total, 35,250. The number of emigrants that embarked from the united kingdom to this colony in 1839 only amounted to 328; while those to Sydney amounted to 8455.[1]

Government.

The supreme authority is vested in a lieutenant-governor and executive council, consisting of the lieutenant-governor, chief-justice, colonial secretary, treasurer, chaplain, attorney-general, and collector of customs, together with eight private gentlemen of the colony, nominated by the crown for life. The governor, with the concurrence of at least two-thirds of the council, possesses the power of making laws, if not repugnant to the laws of England. He, along with the council, may also impose taxes for local purposes. The laws are administered by a supreme court, consisting of a chief-justice and one puisne judge. It is a civil and criminal court. Appeals may be made from its decisions in civil cases, only when the matter exceeds L.1000 in value, and then direct to the king in council. Either judge may hold a court of circuit in different parts of the colony, for the trial of offences, or for civil actions.

Divisions.

Van Diemen's Land was originally divided into two counties, those of Buckingham and Cornwall. These indeed continue to be its only counties, although in 1826 it was divided into nineteen police districts. Orders were then received from the home government for forming this colony into counties, hundreds, and parishes, in the same manner as England. Each of these districts is under the charge of a public magistrate, and a chief and other constables, to whose exertions the good order of the colony is mainly indebted.

Religion, education, &c.

The clergy of the church of England consist of a rural dean, one senior, and seven junior chaplains. Van Diemen's Land is included in the diocese of Australia. There are three Presbyterian ministers, one Independent, one Wesleyan; and one Roman Catholic priest, all paid by the government. The income of the senior chaplain at Hobart-Town is estimated at L.1000 a-year, arising from the glebe, fees, &c. Education is well attended to by the government, which supports the King's Orphan Schools, one for male and another for female children, and seventeen elementary schools throughout the colony. The king's schools are for those who are entirely destitute, or who have one parent living, or whose parents, though both alive, have not the means of giving their children education; and, lastly, for those who are able to contribute annually the sum of L.12. There are besides numerous private seminaries throughout the colony, where all the elementary branches of education are taught. The press is free, and being neither restrained by stamp duties nor taxes on the paper, is conducted with ability and spirit. There are no less than eight newspapers published at Hobart-Town, and two at Launceston, besides monthly magazines, annuals, and almanacks. Various religious, benevolent, and literary institutions are established, which contribute to the improvement of morals, as well as to the diffusion of knowledge.

Revenue, commerce.

The public revenue is derived from customs, duties, excise, fees, sale of land, quit-rents, &c. A duty of five per cent. is imposed on the importation of British goods; of 10s. per gallon on foreign spirits; 7s. 6d. on British gins; and 6d. per pound on tobacco; L.25 a-year on a license to distil spirits; of 5s. on one to bake bread or to slaughter cattle; 5s. to keep a dog on a chain, 10s. off a chain; 5s. to keep a cart for hire. An auctioneer's license costs L.3, 3s.; marriage license, L.4, 4s.; and there are fees, which are equivalent to stamp duties, on grants of land, on the registering of deeds, &c. The annual revenue amounts to L.90,000, of which one half arises from the customs. The expenditure amounts to about the same sum. The staple products of the colony are wool, whale oil, cattle, and provisions, the same as in New South Wales. The following table shows the progress of the trade.

---

Since this period the commerce from Britain does not appear to have increased. In 1838 and 1839 the number of ships that arrived was 41 and 38; the amount of the tonnage 12,598 and 11,946.[1]

In 1834 the imports at Hobart-Town amounted in value to L.355,273, and at Launceston to L.115,961. The exports for the same year were, from Hobart Town, L.117,323, of which oil amounted to L.45,513; wool, L.43,765; and whale-bone, L.8217;—and from Launceston, L.85,919, of which wool was L.59,015. The currency is the same as in the mother country, though dollars, rupees, and other foreign coins are in circulation. There are three banks at Hobart-Town, and one at Launceston, which issue notes, and transact all the ordinary business of money dealers, discounting bills and remitting money, also collecting debt on commission. They have generally carried on a successful business, having divided between twelve and fifteen per cent. on their capital stock.

The progress of this colony in improvement has hitherto been remarkable, and its future prospects are not less promising. With a mild climate exactly adapted to the European constitution, a fruitful soil, and an industrious population, it must continue in its course with increased rapidity. The fine wool which it produces is a great commercial staple, which must command its price in the chief manufacturing districts of Europe; and this valuable produce will increase as cultivation extends over the interior deserts; as well as its surplus produce of grain, which by the introduction of steam engines, may be easily converted into flour, and thus supply a valuable article of exportation. The nature of the country, both in point of climate and soil, presents every inducement to emigrants, who have of late been drawn thither in great numbers, bringing with them their capital, and their European skill and industry. With such external aids, and the natural vigour that exists within, the internal resources of the colony will be developed; the country will rapidly fulfil its destiny, and the time cannot be far distant when we may expect to see a populous and flourishing country redeemed from a wilderness, and exhibiting all the arts and refinements of Europe.

Van Diemen Cape, a cape on Mornington isle, in the gulf of Carpentaria. Long. 139. 49. E. Lat. 16. 32. S.

VANDSHELLING ISLANDS, a cluster of small islands on the south coast of New Guinea. Long. 136. 15. E. Lat 3. 32. S.

VANDYCK, Sir Anthony, a celebrated painter, was born at Antwerp in the year 1599. After giving early proofs of his genius, he became the disciple of the illustrious Rubens. In the church of the Augustines at Antwerp, at the high altar, is a celebrated picture of Rubens, representing, in one part, the Virgin Mary sitting with the child Jesus in her lap, and in another part several saints, male and female, standing. The breast of one of these, St. Sebastian, is said to have been painted by Vandyck when he was only a disciple of Rubens. This great master being engaged one day abroad, his disciples went into his painting-room, where, after having been some time employed in admiring his works, they began to romp in such a manner, that the breast of St. Sebastian, which was not yet dry, was brushed away by a hat thrown at random. This accident put an end to their play: they were very anxious to restore it, fearing that if Rubens discovered it they should all be discarded. At length it was agreed that Anthony should undertake to mend the saint's breast. In short, taking his master's pallet and brushes, he succeeded so well that his companions imagined Rubens would overlook it. They were mistaken; for Rubens at his return knew immediately that some one had touched his performance: calling his disciples, he asked them why any one had dared to meddle with his painting. They were some time doubtful whether they should confess or deny the fact. Threats at length prevailed; they owned that Vandyck had thrown his hat upon it. Upon this, closeting Vandyck, instead of chiding him, he told him, that "it was proper and even necessary for him to travel into Italy, the only school that produced excellent painters." By this advice, and with the assistance of his master, he set out for Italy, about the year 1621, being then about twenty-one or twenty-two years of age. Having staid a short time at Rome, he removed to Venice, where he attained the beautiful colouring of Titian, Paul Veronese, and the Venetian school.

After a few years he returned to Flanders, with so noble, so easy, and natural a manner of painting, that Titian himself was hardly his superior; and no other master could equal him in portraits. Soon after his return, he accidentally met with D. Teniers, who accosted him with great politeness, and asked him whether he had much business since he came from Rome? "What business, think you, can I have had time to do?" replied Vandyck: "I am only just arrived here. Would you believe, that I offered to draw that fat brewer's picture who just passed by us for two pistoles, and that the looby laughed in my face, saying it was too dear? I assure you, that if the cards do not turn up better, I shall make no long stay at Brussels." Soon after this, he painted those two famous pictures, the Nativity and a dying Christ; the first in the parish church, the second in that of the Capuchins, at Termond.

Vandyck, finding he could not make a fortune in his own country, adopted the resolution of visiting England. Accordingly he borrowed some guineas of Teniers, and set out, furnished with letters of recommendation. His superior genius soon brought him into great reputation; and above all, he excelled in portraits, which he drew with an in nceivable facility, and for which he charged a very hi price, according to the instructions which had been gi n him on that head. It is affirmed, that for some of th n he received 400 guineas a-piece. He soon found hi self loaded with honours and riches; and as he had a ble and generous heart, he lived suitably to his fortune. H married Maria Ruthven, grand-daughter of the first earl of owrie; and though she had but little fortune, maintained he in a style equal to her birth. He generally kept a magni ent equipage, and a numerous retinue. He died in Bl kfriars on the 9th of December 1641, at the early age of rty-two, and was buried in St. Paul's near the tomb of Jo of Gaunt. He left a daughter, married to Mr. Stepne the grandfather of George Stepney the poet. Lady V dyck was afterwards married to Richard the son of Sir Jo Pryse of Newton-Averbecham, but by her second hu band she had no issue,

ANE, a thin slip of bunting hung to the mast-head, or so other conspicuous place in the ship, to show the directi of the wind. It is commonly sewed upon a wooden frame ca d the *stock*, which contains two holes for slipping over th spindle, upon which it turns about as the wind changes.

ANNES, an arrondissement in the department of Morbi n in France, extending over 638 square miles, compr ending eleven cantons, divided into seven communes, an containing a population of 125,898 in 1836. The capita the city of the same name, which is connected with the gu of Morbihan by a canal about two and a half miles in le th. It is well fortified, is the seat of a bishop, has a cath ral and other three churches, 1850 houses, and 11,623 in bitants in 1836. The chief trade is in corn, butter, and ho y; and a fishery for anchovies affords occupation to m y of the people. Lat. 47. 39. 14. Long. 2. 52. 16. W.

AR, a department of the south-east of France, formed ou of the eastern part of ancient Provence. It extends in no h latitude from 43° 2′ to 44° 0′, and in east longitude fr 5° 29′ to 6° 59′ and comprehends 2854 square miles. It bounded on the north by the department of the Lower A , on the north-east by Piedmont, on the south-east an the south by the Mediterranean sea, and on the west by he mouths of the Rhone. It is divided into four arrondi ments, which are subdivided into thirty-five cantons, an those into 210 communes.

he population in 1836 amounted to 323,404 persons, al f whom adhere to the Romish communion, or, if there ar any protestants, they are in no place so numerous as to fo a congregation for public worship. The language of th common people is the Provençal, but in the cities an towns the French is gradually driving out the ancient to gue. The face of the country presents mountains, rocks, hi , valleys, and small plains, with some beautiful and even ro antic prospects. The north and north-east parts are th most mountainous, as they contain a portion of the m itime Alps, proceeding out of Piedmont, which, for the m t part, are bare of trees, and, especially on their south si s, exhibit naked perpendicular precipices. These are al calcareous, but a range extends from Hieres to Frejus, wh ch are of granite, and more thick of trees, among which ar cork, chesnut, cestus, myrtle, and firs. In the western pa is the remarkable mountain Saint Beaume, with a lab nth in the calcareous substance of it, that extends from th western boundary of the department, the mouths of the R ne, to Ollioules, and is well known by the name of *les V ux d'Ollioules*. In general the soil is far from fertile, an is more indebted to the labour of the inhabitants than to ts quality for its powers of production. It is better ad pted for fruits, such as grapes and olives, than for wheat, b ey, or other grain.

he department is watered by numerous mountain st ams. The river which gives name to the department, ri s in the mountain Camelione in Piedmont, receives the water of the Esteron, forms many small islands, and, after a course of sixty miles, enters the Mediterranean; but it is not navigable in any part. Along the sea-shore are numerous pools and morasses, some of which communicate with the sea.

The climate is mild, the great heats of summer being tempered by the breezes from the sea and the mountains. Rain is unusual, except when the wind drives the clouds from the sea. With the exception of about twenty days, there is a continual spring; and even in those few days the thermometer seldom sinks to the freezing point. In January the fields are clothed with fresh green, and in February the trees put forth their blossoms.

Agriculture is in a neglected state, so that the corn produced does not supply half the consumption, and in summer the grass is so burnt up, that the cattle must be driven to the mountains for pasture. Neither cows, sheep, nor horses are abundant, but many swine are bred and fattened. The chief beasts of burden are asses and mules.

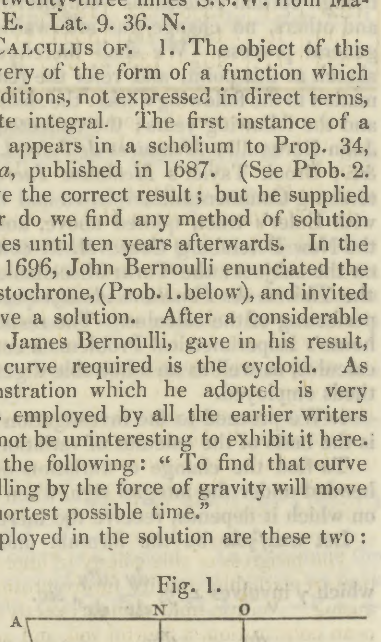
The chief productions are wine, oil, silk, and the better kinds of fruit, oranges, citrons, and lemons, some dried fruits, a few dates, and abundance of chesnuts and other kinds of nuts. Honey and wax are collected in considerable quantities. There are no minerals raised, except about 600 tons of fossil coal. On the sea-shore a sufficiency of salt is produced by the natural heat of the sun. The fishery on the coast yields abundance of tunny, anchovies, sardinias, and mackerel, with a small but delicate small fish called the monnat. The manufactures are inconsiderable, and merely for home consumption. The department elects three deputies for the legislative chamber.

VARDOOSETTAH, a town of Hindustan, in the province of Tinnevelly, twenty-three miles S.S.W. from Madura. Long. 78. 11. E. Lat. 9. 36. N.

VARIATIONS, Calculus of. 1. The object of this calculus is the discovery of the form of a function which shall fulfil certain conditions, not expressed in direct terms, but involved in a finite integral. The first instance of a problem of this kind appears in a scholium to Prop. 34, b. ii. of the *Principia*, published in 1687. (See Prob. 2. below.) Newton gave the correct result; but he supplied no demonstration, nor do we find any method of solution applicable to such cases until ten years afterwards. In the *Acta Eruditorum* for 1696, John Bernoulli enunciated the problem of the brachystochrone, (Prob. 1. below), and invited mathematicians to give a solution. After a considerable interval, his brother, James Bernoulli, gave in his result, which was, that the curve required is the cycloid. As the mode of demonstration which he adopted is very nearly that which was employed by all the earlier writers on the subject, it will not be uninteresting to exhibit it here.

2. The problem is the following: "To find that curve down which a body falling by the force of gravity will move from A to B in the shortest possible time."

Fig. 1.



The principles employed in the solution are these two: 1st, that when a quantity is a maximum or minimum, a slight change in the variables will produce no variation in the value of the function; 2d, that what is true of the whole quantity is likewise true of every portion of it.

The second principle requires that the time down PQR should be less than the time down any other line, as PSR;

and by applying the first principle to this property, we deduce the fundamental equation,

time down PQR = time down PSR *ultimately.*

Hence,

$$\frac{\text{PQ}}{\text{velocity at Q}}+\frac{\text{QR}}{\text{v}^{\text{y}}\text{. at R}}=\frac{\text{PS}}{\text{v}^{\text{y}}\text{. at Q}}+\frac{\text{SR}}{\text{v}^{\text{y}}\text{. at R}}\ \textit{ultimately;}$$

$$\text{or } \frac{\text{PQ}-\text{PS}}{\sqrt{\text{NS}}}=\frac{\text{SR}-\text{QR}}{\sqrt{\text{OR}}},\ \text{or } \frac{\text{Q}e}{\sqrt{\text{NS}}}=\frac{\text{S}c}{\sqrt{\text{OR}}}\ \textit{ultimately;}$$

$$\text{that is, } \frac{\cos.\angle \text{SQ}e}{\sqrt{\text{NS}}}=\frac{\cos.\angle \text{QS}c}{\sqrt{\text{OR}}}\ \textit{ultimately;}$$

$$\text{or } \frac{\sin.\angle\text{, which curve makes with vertical at Q}}{\text{do.} \qquad\qquad \text{do.} \qquad\qquad \text{R}}=\frac{\sqrt{\text{NS}}}{\sqrt{\text{OR}}},$$

a well-known property of the cycloid.

3. Of the two principles employed in this solution, the first is equivalent to the theorem demonstrated in FLUXIONS, art. 62, and is the basis of all solutions. The second, although in the case in question it is actually true, is an assumption not warranted by the nature of the problem. It does not appear that any geometrical solution is exempt from this objection, and we cannot in consequence date the existence of the Calculus of Variations earlier than 1744, when Euler published his treatise, entitled *Methodus inveniendi Lineas Curvas proprietate maximi minimive gaudentes.* This work was followed by a memoir from the pen of Lagrange, published in the second volume of the *Miscellanea Taurinensia.* By the introduction of the symbol δ to express that change which is termed a *variation*, Lagrange may be said to have perfected the calculus; for although certain extensions were afterwards made by himself and others, no change was afterwards introduced into the general process. We shall therefore conclude our brief sketch at this point, and refer the reader for further information to the following works: the *Acta Eruditorum* for 1696 and the following years; the collected works of James and John Bernoulli; *Memoires de l'Acad. des Sci.* 1706, 1718, &c.; Brook Taylor's *Methodus Incrementorum;* the Petersburg Commentaries, vols. vi. and viii.; which, together with Euler's tract, quoted above, and his last memoir in the New Petersburg Com. vol. x. contain Euler's writings on the subject: the Turin Miscellanies, vols. ii. and iv. and the *Théorie des Fonctions Analytiques*, contain Lagrange's perfecting of the calculus. The reader will find in Woodhouse's Isoperimetrical Problems a complete history of the calculus, as well as an admirable digest of the different methods employed.

4. We proceed to the investigation of the theorem which is the basis of the calculus of variations.

To find the change or variation of a formula comprehended under the integral sign, when the variables x and y, on which it depends, receive the increments δx and δy.

Let $u=\int\gamma dx$ be the formula under consideration; in which γ involves x, y, $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$, &c.

Denote $\frac{dy}{dx}$ by p, $\frac{d^2y}{dx^2}$ by q, &c.; the partial differential coefficients $\frac{d\gamma}{dx}$ by M, $\frac{d\gamma}{dy}$ by N, $\frac{d\gamma}{dp}$ by P, &c.; the increment of $\int\gamma dx$ by $\delta\int\gamma dx$, &c.

$$\text{Then } \delta u=\int(\gamma+\delta\gamma)(dx+d\delta x)-\int\gamma dx,$$
$$=\int\delta\gamma dx+\int\gamma d\delta x,$$
$$=\int\delta\gamma dx+\gamma\delta x-\int\delta x d\gamma.$$

$$\text{Now } \int dx\delta\gamma=\int dx(\text{M}\delta x+\text{N}\delta y+\text{P}\delta p+\ldots),$$
$$\text{and } \int\delta x d\gamma=\int\delta x(\text{M}dx+\text{N}dy+\text{P}dp+\ldots),$$

$$\therefore \delta u=\gamma\delta x+\int\{\text{N}(dx\delta y-\delta x dy)+\text{P}(dx\delta p-\delta x dp)+\ldots\},$$
$$=\gamma\delta x+\int\{\text{N}(\delta y-p\delta x)+\text{P}(\delta p-q\delta x)+\ldots\}dx.$$

Also if $\delta y-p\delta x$ be denoted by ω, we have

$$\delta p-q\delta x=\frac{d(y+\delta y)}{d(x+\delta x)}-\frac{dy}{dx}-\frac{dp}{dx}\delta x,$$
$$=\frac{d\delta y}{dx}-p\frac{d\delta x}{dx}-\frac{dp}{dx}\delta x,$$
$$=\frac{d\delta y}{dx}-\frac{d}{dx}(p\delta x)=\frac{d}{dx}(\delta y-p\delta x)=\frac{d\omega}{dx}:$$

hence putting p for y and $\therefore$ q for p, we obtain

$$\delta q-r\delta x=\frac{d}{dx}(\delta p-q\delta x)=\frac{d}{dx}\cdot\frac{d\omega}{dx}=\frac{d^2\omega}{dx^2},$$
$$\&\text{c.}=\&\text{c.}$$

By substitution,

$$\delta u=\gamma\delta x+\int\left\{\text{N}\omega+\text{P}\frac{d\omega}{dx}+\text{Q}\frac{d^2\omega}{dx^2}+\ldots\right\}dx.$$

$$\text{But } \int\text{P}\frac{d\omega}{dx}dx=\text{P}\omega-\int\omega\frac{d\text{P}}{dx}dx,$$
$$\int\text{Q}\frac{d^2\omega}{dx^2}dx=\text{Q}\frac{d\omega}{dx}-\omega\frac{d\text{Q}}{dx}+\int\omega\frac{d^2\text{Q}}{dx^2}dx,$$
$$\&\text{c.}=\&\text{c.}$$

$$\therefore \delta u=\gamma\delta x+\omega\left(\text{P}-\frac{d\text{Q}}{dx}+\frac{d^2\text{R}}{dx^2}-\&\text{c.}\right)$$
$$+\frac{d\omega}{dx}\left(\text{Q}-\frac{d\text{R}}{dx}+\ldots\right)$$
$$+\ \&\text{c. }\&\text{c.}$$
$$+\int\omega\left(\text{N}-\frac{d\text{P}}{dx}+\frac{d^2\text{Q}}{dx^2}-\&\text{c.}\right)dx.$$

The last line of this very elegant expression is due to Euler; the rest of the formula to Lagrange.

Let x_o x_1, y_o y_1, be the values of x and y at the two limits; then the whole value of δu between the limits is,

$$\delta u=\gamma_1\delta x_1-\gamma_o\delta x_o+\omega_1(\text{P}_1-\&\text{c.})-\omega_o(\text{P}_o-\&\text{c.})$$
$$+\ \&\text{c.}+\int_{x_o}^{x_1}\omega\left(\text{N}-\frac{d\text{P}}{dx}+\frac{d^2\text{Q}}{dx^2}-\&\text{c.}\right)dx$$

5. To satisfy the conditions of a maximum or minimum value of u, the value of δu, expressed only as far as to the first powers of δx_o, δy_o, &c., must be equal to zero.

But this quantity consists of two parts; the one an integrated expression, depending only on the values of δx_o, δy_o, &c.; the other an unintegrated expression, depending on the general values of δx, δy. Now it is evidently possible to make the latter expression assume an infinity of different values, corresponding to an assigned value of the former. It is therefore impossible to render the whole expression equal to zero for all values of ω, without making the two parts separately zero.

Our conditions are therefore,

$$\text{N}-\frac{d\text{P}}{dx}+\frac{d^2\text{Q}}{dx^2}-\&\text{c.}=0. \qquad (1.)$$

$$\gamma_1\delta x_1-\gamma_o\delta x_o+\omega_1(\text{P}_1-\&\text{c.})-\omega_o(\text{P}_o-\&\text{c.})=0. \quad (2.)$$

6. It may be remarked, that the object of our investigation is to discover a mode of satisfying certain conditions, by means of establishing a relation between y and x. To effect this, we seek to separate these quantities from the quantities δx and δy. This will explain why the unintegrated part of the expression has been reduced to the form in which we left it. Had ω been implicated with x and y,

a r ation would have been assigned, not between x and y, bu etween x, y, and ω. We may add, that if $\int\gamma dx$ be an int rable expression, the equation (1) is an identical equatio

In the above investigation it has been assumed that th other quantities which enter into the function γ, togethe with x and y, are absolute constants. If this hypothesis e not correct, our formulæ require to be modified.

ippose a, b, &c., to enter the function γ.

et $\delta\gamma=\mathrm{M}\delta x+\mathrm{N}\delta y+\mathrm{P}\delta p+$ &c. $+\mathrm{A}\delta a+$ &c...., th the addition to be made to the expression for δu is $\int(\delta a+\ldots)dx$. But δa &c. depend not on the general variaon, but only on the variation at the limits, (see Prob. 4); he e they are independent of δx and δy, and consequently for part of equation (2), which thus becomes

$$\gamma_1\delta -\gamma_o\delta x_o+\omega_1(\mathrm{P}_1-\&c.)-\omega_o(\mathrm{P}_o-\&c.)+\delta a\int_{x_o}^{x_1}\mathrm{A}dx+\&c.=0. \quad (3.)$$

Had our object been merely to determine the *form* of a nction which should satisfy certain conditions, we might ha rested content with causing one of the quantities, as x ly, to vary. By this means equation (1) would have be obtained. There are however many problems which de end on the relation between δx and δy, at least at the li ts, (see Prob. 3.) At the commencement of the variati, for instance, we cannot remove to any point we please, fr the circumstance that we are compelled to *begin* in a ce ain manner. Hence equation (2) is a most important pa of the result; and by assigning a relation between the th gs given and sought at the extremities, shews us the p tion of the extremities of the curve, and thereby rest ts the solution from a *kind* of curve (as a cycloid) to a *sp ific* curve, (a cycloid of known dimensions and position).

From equation (1) we might easily deduce a number of xpressions, for particular cases, easy of application. T s, if γ contains only y and p, the formula (1) gives

$$\mathrm{N}-\frac{d\mathrm{P}}{dx}=0.$$

H ce $d\gamma=\mathrm{N}dy+\mathrm{P}dp=\frac{d\mathrm{P}}{dx}dy+\mathrm{P}dp=d\mathrm{P}\,.p+\mathrm{P}dp$

$$=d(\mathrm{P}p);\ \text{and}\ \gamma=\mathrm{P}p+c. \quad (4.)$$

B as the reader will readily supply such formulæ for hi self, we proceed to exhibit the solution of a few proble s.

rob. 1. To find the curve of quickest descent from one g en point to another.

et x and y be the co-ordinates of a point in the curve, y eing measured vertically downwards from the upper p nt.

Then $t=\frac{1}{\sqrt{2g}}\int\frac{\sqrt{1+p^2}dx}{\sqrt{y}}$; in which the quantity c responding to γ contains only y and p.

$\gamma=\frac{\sqrt{1+p^2}}{\sqrt{y}}$, $\mathrm{P}=\frac{p}{\sqrt{1+p^2}\,.\sqrt{y}}$; and formula (4) gives

$$\frac{\sqrt{1+p^2}}{\sqrt{y}}=\frac{p^2}{\sqrt{1+p^2}\,.\sqrt{y}}+c,\ \text{or}\ \frac{ds}{dx}=\frac{1}{c\sqrt{y}};$$

ich is the differential equation to a cycloid. We may ve the problem by taking x as the vertical co-ordinate, which case γ will contain only p, and equation (1) will e $\frac{d\mathrm{P}}{dx}=0$, or $\mathrm{P}=c$.

But P, in this case, is $\frac{p}{\sqrt{1+p^2}\,.\sqrt{x}}$; $\therefore\frac{ds}{dy}=\frac{1}{c\sqrt{x}}$, the same result as before, with the exception that x and y are interchanged. The solution of this equation shews that the cusp of the cycloid is at the highest point, and its axis vertical.

Prob. 2. Required the curve which by revolution round its axis generates the solid on which the resistance produced by motion in a fluid shall be less than on any other curve having the same extreme co-ordinates.

The resistance varies as $\int\frac{yp^3}{1+p^2}dx$; $\therefore$ by formula (4)

$$\frac{yp^3}{1+p^2}=\left(\frac{3yp^2}{1+p^2}-\frac{2yp^4}{(1+p^2)^2}\right)p+c,$$

$$\text{or}\ 0=\frac{2yp^3}{(1+p^2)^2}+c.$$

This equation expresses the same property as that which Newton, without demonstration, assigned to the curve.

Prob. 3. To find the shortest distance between two given curves.

The expression for γ is here $\sqrt{1+p^2}$ where, as the line on which the distance is measured is a right line, $p=c$. But by formula (2)

$\gamma_1\,\delta x_1-\gamma_o\,\delta x_o+\mathrm{P}_1\omega_1-\mathrm{P}_o\omega_o=0$, when δx_1, &c. are indefinitely small. Also, if the curves have no connexion, we may make $\delta x_1\ \delta y_1$ assume what values soever we please, without affecting δx_o, δy_o; we must therefore have separately

$$\gamma_1\,\delta x_1+\mathrm{P}_1\omega_1=0,\ \text{and}\ \gamma_o\,\delta x_o+\mathrm{P}_o\omega_o=0.$$

The latter gives $\sqrt{1+p_o^2}\,\delta x_o+\frac{p_o}{\sqrt{1+p_o^2}}(\delta y_o-p_o\delta x_o)=0$,

or $\delta x_o+p_o\delta y_o=0$, or $\frac{\delta y_o}{\delta x_o}=-\frac{1}{p_o}=-\frac{1}{c}$, when δx_o and δy_o are indefinitely diminished.

But, since the measurement must begin *in* the first curve, the limit of $\frac{\delta y_o}{\delta x_o}$ expresses the tangent of the angle in which the tangent to the first curve cuts the axis. Our equation, then, shews that the line of shortest distance cuts the first curve at right angles. For the same reason it cuts the second curve also at right angles. Its position is consequently determined.

Prob. 4. To find the curve of quickest descent from one given curve to another.

Let h be the vertical ordinate of the point at which motion begins:

then $t=\frac{1}{\sqrt{2g}}\int\frac{\sqrt{1+p^2}}{\sqrt{y-h}}dx$, from which (by Prob. 1.) it is evident that the curve is a cycloid. To determine the angles at which the cycloid cuts the given curves, we have the following equation, (3): $\gamma_1\,\delta x_1-\gamma_o\delta x_o+\mathrm{P}_1\,\omega_1-\mathrm{P}_o\,\omega_o+\delta h\int\frac{d\gamma}{dh}dx=0$. The problem admits of several cases.

1. If the body starts from a given point in the first curve, that curve performs no part in the problem. Here δx_o, ω_o, and δh, are all zero.

$$\therefore\ \gamma_1\,\delta x_1+\mathrm{P}_1\,(\delta y_1-p_1\delta x_1)=0.$$

But $\gamma_1-\mathrm{P}_1p_1=c$, (see Prob. 1.)

$$\therefore\ \frac{1}{\sqrt{1+p_1^2}\ \sqrt{y_1-h}}=c,\ \text{and}\ \mathrm{P}_1=\frac{p_1}{\sqrt{1+p_1^2}\sqrt{y_1-h}}=p_1c,$$

$\therefore\ c\delta x_1+p_1\,c\delta y_1=0$; or $\frac{dy}{dx}$ for the second curve, at the point in which the cycloid cuts it, is equal to $-\frac{1}{p_1}$: which shews that the curve and cycloid cut each other at right angles.

2. If the motion is supposed to commence at the same horizontal line, whatever be the point at which the body reaches the first curve; we have $h=d$ constant, and the equation gives

$\gamma_1\delta x_1-\gamma_o\delta x_o+P_1\omega_1-P_o\omega_o=0$, from which it is evident, as in Problem 3, that the cycloid cuts both curves at right angles.

3. If motion begins at the first curve, $h=y_o$, and $\frac{d\gamma}{dh}=-\frac{d\gamma}{dy}=-N=-\frac{dP}{dx}\left(\because N-\frac{dP}{dx}=0\right)$; hence our equation becomes

$$\gamma_1\delta x_1-\gamma_o\delta x_o+P_1\omega_1-P_o\omega_o-\delta y_o\int_{x_o}^{x_1}\frac{dP}{dx}\,dx=0,$$

or $\gamma_1\delta x_1+P_1\omega_1=0$, $\gamma_o\delta x_o+P_o\omega_o+\delta y_o(P_1-P_o)=0$.

From the first of these it follows that the lower curve is cut at right angles. The second gives

$$(\gamma_o-P_op_o)\delta x_o+P_1\delta y_o=0, \text{ or } c+P_1\frac{\delta y_o}{\delta x_o}=0.$$

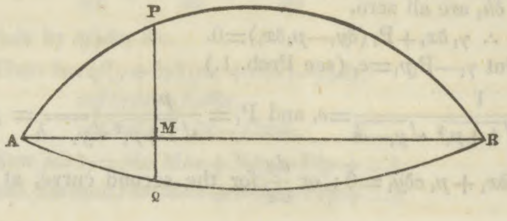
Also the first equation is $c+P_1\frac{\delta y_1}{\delta x_1}=0$.

$\therefore \frac{\delta y_o}{\delta x_o}=\frac{\delta y_1}{\delta x_1}$; from which it appears that the tangents to the two curves at the two points of section are parallel to one another.

10. We have hitherto solved only problems of absolute maxima and minima. But a very simple consideration will enable us to apply the same formulæ to the investigation of relative maxima and minima. The problem of isoperimetricals (prob. 5 below) will illustrate this class of questions. Here the integrated function is not required to be a maximum or a minimum absolutely, but only one consistent with the further condition that another integrated function shall not change its value. Although, therefore, $\delta\int y\,dx$ is actually zero, yet δx and δy are not, as in our previous investigations, *any* quantities whatever, but only such as will consist with the required condition that $\delta\int\sqrt{1+p^2}\,dx$ shall also be zero. To Euler we owe the idea of substituting for the quantity u, which is made to vary, not $\int y\,dx$, as in other cases, but $\int y\,dx+a\int v\,dx$; $\int v\,dx$ being the quantity which is to remain unchanged. By this substitution we determine the relation between x and y, which renders $\gamma+av$ a maximum or a minimum. But as that relation involves the arbitrary constant a, we restrict it by assigning to that quantity such a value as shall render $\int v\,dx$ of the required magnitude. We have therefore found a relation, which not only makes the sum of two quantities a maximum or a minimum, but which likewise reduces one of those quantities to a specified value. This relation then evidently makes the other quantity a maximum or a minimum. Thus the problem is solved in all its generality.

Prob. 5. AB is a given line, PMQ a line perpendicular to AB at the point M. The points P and Q are supposed to generate two curves by the motion of the line perpendicular to AB, having a relation such, that although both are unknown, PM is a known function of QM. It is required to determine both curves, when the length of AQB is given, and the area APBMA is a maximum.

Fig. 2.



Let $QM=y$, then $PM=f(y)$, where f is a known function.

Also length $AQB=\int\sqrt{1+p^2}\,dx$, and area $APB=\int f(y)\,dx$, the limits of both integrals being the same.

$$\therefore \gamma=f(y)+a\sqrt{1+p^2},$$

and by formula (4) $f(y)+a\sqrt{1+p^2}=\frac{ap^2}{\sqrt{1+p^2}}+c$,

$$\text{or } \{c-f(y)\}\sqrt{1+p^2}=a,$$

the differential equation to the curve AQB.

If $y=\phi(x)$ be the solution of this equation, $y=f\{\phi(x)\}$ is the equation to the curve APB.

Cor. If $f(y)=y$, we get $a^2=(c-y)^2+(c'-x)^2$, the equation to a circle.

Prob. 6. To find the curve which, *with a given length*, contains between its chord and its arc the greatest possible area.

By cor. to last problem the equation is $a^2=(c-y)^2+(c'-x)^2$.

Let the origin be at A and $AB=2r$; then since $y=0$, both when $x=0$ and $x=2r$, we get

$$y^2-2cy=2rx-x^2.$$

And from the equation to the limits $(\gamma_1-P_1p_1)\delta x_1=0$, or $\gamma_1-P_1p_1=0 \therefore c=0$; and the curve required is the semicircle.

Prob. 7. Given the length of the curve contained between two points in a horizontal line; required its nature, that the centre of gravity of the arc may be the lowest possible. Here we have to make $\int x\sqrt{1+p^2}\,dx$ a maximum, whilst $\int\sqrt{1+p^2}\,dx$ is constant.

$$\therefore \gamma=x\sqrt{1+p^2}+a\sqrt{1+p^2}, \text{ and } \frac{dP}{dx}=0, P=c,$$

$$\text{or } \frac{p(x+a)}{\sqrt{1+p^2}}=c,$$

the integral of which is $y=c\log.(x+a+\sqrt{(x+a)^2-c^2})+e$, the equation to the catenary.

The solution of more complicated problems is not consistent with our limits. For the investigation of formulæ in cases where γ involves an integral, or where it is given by a differential equation, the reader is referred to Woodhouse's Treatise. Considerations on the mode of distinguishing a maximum from a minimum will be found in Lagrange's *Theorie des Fonctions Analytiques.*

VARIATION *of the Compass.* See MAGNETISM.

VARIATION, in *Music*, means either the change induced upon a melody by embellishments given by the vocal or instrumental performer, or the new forms and more studied ornaments given by a composer to a theme of his own or to some popular air. Among instrumental variations, some of the most beautiful are to be found in Hadyn's andante movements, and in Mozart and Beethoven's variations to their own andantes, or to popular themes on which they have displayed their skill and genius.

VARNA, a city of Turkey in Europe in the province of Silistra. It stands on the Black sea, at the mouth of the river of the same name. It is strongly fortified, and considered as one of the most important defences o· the southern division of Turkey in Europe. The obstinate defence of it, in the late war with Russia, shows both its strength and its consequence. The harbour is good, and is the only one b nging to Turkey on that side of the Black sea. It is th seat of a Greek bishop, under whom are two churches. T ere are twelve mosques, 4000 houses, and about 20,000 in ibitants, among whom are a few Franks, and many Arm ians, Greeks, and Jews. Varna has considerable shippi and fisheries, and much trade in corn, butter, cheese, ar wine. Lat. 43. 17. 30. Long. 27. 45. E.

ARNISH, a clear limpid fluid, capable of hardening wi out losing its transparency, used by painters, gilders, &c to give a lustre to their works, in order to preserve th and defend them from the air.

coat of varnish ought to possess the following propertie 1st, It must exclude the action of the air; because wo l and metals are varnished to defend them from decay an rust. 2d, It must resist water; for otherwise the effect of e varnish could not be permanent. 3d, It ought not to lter such colours as are intended to be preserved by thi means. It is necessary therefore that a varnish should be asily extended or spread over the surface, without lea ng pores or cavities; that it should not crack or scale; an that it should resist water. Now resins are the only bo es that possess these properties. Resins consequently mu be used as the bases of varnish. The question which of urse presents itself must then be, how to dispose them for his use; and for this purpose they must be dissolved, as inutely divided as possible, and combined in such a ma ner that the imperfections of those which might be dis sed to scale may be corrected by others.

esins may be dissolved by three agents. 1st, By fixed oil. 2d, By volatile oil. 3d, By alcohol. And accordingly we have three kinds of varnish; the fat or oily varnish, ess tial varnish, and spirit varnish. Before a resin is dissol d in a fixed oil, it is necessary to render the oil drying. Fo his purpose the oil is boiled with metallic oxides; in wh operation the mucilage of the oil combines with the me l, while the oil itself unites with the oxygen of the oxi . To accelerate the drying of this varnish, it is neces ry to add oil of turpentine. The essential varnishes con st of a solution of resin in oil of turpentine. The var sh being applied, the essential oil flies off, and leaves the esin. This is used only for paintings. When resins are lissolved in alcohol, the varnish dries very speedily, and s subject to crack; but this fault is corrected by adding small quantity of turpentine to the mixture, which ren rs it brighter, and less brittle when dry.

e shall now give the method of preparing a number of rnishes for different purposes.

Varnish for Toilet-boxes, Cases, Fans, &c.—Dissolve tw unces of gum mastich and eight ounces gum sandarach a quart of alcohol; then add four ounces of Venice tur ntine.

Varnish for Wainscots, Cane Chairs, Iron Chairs, Gr es.—Dissolve in a quart of alcohol eight ounces of gu sandarach, two ounces of seed lac, four ounces of ros ; then add six ounces of Venice turpentine. If the var sh is wished to produce a red colour, more of the lac an ess of sandarach should be used, and a little dragon's blo should be added. This varnish is so thick that two lay of it are equal to four or five of another.

Varnish for Fiddles, and other Musical Instrumen.—Put four ounces of gum sandarach, two ounces of , two ounces of gum mastich, an ounce of gum ele , into a quart of alcohol, and hang them over a slow fire ill they are dissolved; then add two ounces of turper e.

rnish in order to employ Vermilion for painting Equipag .—Dissolve in a quart of alcohol six ounces of sandarach hree ounces of gum lac, and four ounces of rosin; afte ards add six ounces of the cheapest kind of turpentin mix with it a proper quantity of vermilion when it is to l used.

Gold-coloured Varnish.—Pound separately four ounces of stick lac, four ounces of gamboge, four ounces of dragon's blood, four ounces of anotta, and one ounce of saffron: put each of them separately into a quart of alcohol, and expose them for five days in a narrow-mouthed bottle to the sun, or keep them during that time in a very warm room, shaking them every now and then to hasten the solution. When they are melted, mix them together. More or less of each of these ingredients will give the different tints of gold according as they are combined. In order to make silver imitate gold exactly when covered with this varnish, the quantity of ingredients must be somewhat greater. The method of gilding silver leaf, &c. with this varnish, is as follows: The silver leaf being fixed, in the same manner as gold leaf, by the interposition of proper glutinous matters, the varnish is spread upon the piece with a brush or pencil. The first coat being dry, the piece is again and again washed over with the varnish till the colour appears sufficiently deep. What is called *gilt leather*, and many picture frames, have no other than this counterfeit gilding. Washing them with a little rectified spirit of wine affords a proof of this; the spirit dissolving the varnish, and leaving the silver leaf of its own whiteness. For plain frames, thick tinfoil may be used instead of silver. The tin leaf, fixed on the piece with glue, is to be burnished, then polished with emery and a fine linen cloth, and afterwards with putty applied in the same manner: being then lacquered over with the varnish five or six times, it looks very nearly like burnished gold. The same varnish, made with a less proportion of the colouring materials, is also applied on works of brass; both for heightening the colour of the metal to a resemblance with that of gold, and for preserving it from being tarnished or corroded by the air.

Oil Varnishes.—Gum copal and amber are the substances principally employed in oil varnishes. They possess the properties necessary for varnishes, solidity and transparency. The copal being whitest, is used for varnishing light, the amber for dark colours. It is best to dissolve them before mixing them with the oil, because by this means they are in less danger of being scorched, and at the same time the varnish is more beautiful. They should be melted in a pot on the fire; they are in a proper state for receiving the oil when they give no resistance to the iron spatula, and when they run off from it drop by drop. The oil employed should be a drying oil, and perfectly free from grease. It should be poured into the copal or amber by little and little, constantly stirring the ingredients at the same time with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when it is pretty cool, pour in a greater quantity of the essence of turpentine than the oil that was used. After the varnish is made, it should be passed through a linen cloth. Oil varnishes become thick by keeping; but when they are to be used, it is only necessary to pour in a little essence of turpentine, and to put them for a little on the fire. The turpentine is necessary in oil varnishes to make them dry properly; generally twice as much of it is used as of oil. Less is necessary in summer than in winter. Too much oil hinders the varnish from drying; but when too little is used, it cracks and does not spread properly. We shall subjoin the most useful oil varnishes.

White Copal Varnish.—On sixteen ounces of melted copal pour four, six, or eight ounces of linseed oil, boiled and quite free from grease. When they are well mixed, take them off the fire (not forgetting to stir them properly); and when pretty cool, pour in sixteen ounces of the essence of Venice turpentine. Pass the varnish through a cloth. Amber varnish is made in the same way.

Black Varnish for Coaches and Iron Work.—This varnish is composed of bitumen of Palestine, rosin, and amber, melted separately, and afterwards mixed: the oil is then added, and afterwards the turpentine, as directed above. The usual proportions are, twelve ounces of amber, two ounces of rosin, two ounces of bitumen, six of oil, and twelve of the essence of turpentine. Golden coloured varnish may be made also by substituting linseed oil for alcohol.

Essential Oil Varnishes.—The only essential oil varnishes used are for pictures. Picture varnishes should be white, light, and quite transparent, which will preserve the colours without giving them any disagreeable tint; and it should be possible to take them off the picture without injuring it. They are usually made of gum mastich and turpentine dissolved together in some essential oil. The varnish is passed through a cloth, and allowed to clarify. It is applied cold to the picture.

Varnish for Glass in order to preserve it from the rays of the Sun.—Pulverize a quantity of gum adragant, and let it dissolve for twenty-four hours in the white of eggs well beat up; then rub it gently on the glass with a brush.

Varnishes, before they are used, should be carefully kept from dust, which would spoil them; and they should be kept in a vessel quite clean and dry. When used, they should be lifted lightly with a brush, and spread upon a ground altogether free from dirt and moisture. The substance, after being varnished, should be exposed to the heat of the sun, or placed in a warm room covered with a glass case, to keep out all filth. Oil varnishes require more heat than alcohol varnishes. The varnish should be put on very quickly, making great strokes with the pencil or brush, taking care that these strokes never cross one another; it should be spread equally, and never thicker than a leaf of paper; a second coat should never be put on till the first is quite dry. If the varnish, after being put on, becomes dull and uneven, it must be taken off entirely, and new varnish applied.

When wainscot is to be varnished, it is first painted of a wooden colour. This colour is made by infusing in water either red or yellow ochre (according to the colour wished for), terra ombria (a kind of ochre) and white lead; into this as much as necessary is put of *parchment paste*. Two thin coats of this are to be put on, and, after they are quite dry, the varnish.

Varnishes are polished with pumice-stone and Tripoli earth. The pumice-stone must be reduced to an impalpable powder, and put upon a piece of serge moistened with water; with this the varnished substance is to be rubbed lightly and equally. The Tripoli must also be reduced to a very fine powder, and put upon a clean woollen cloth moistened with olive oil, with which the polishing is to be performed. The varnish is then to be wiped with soft linen, and, when quite dry, cleaned with starch or Spanish white, and rubbed with the palm of the hand or with a linen cloth.

To recover colours or varnish, and to take off the dirt and filth which may adhere to them, a ley is used made of potash and the ashes of lees of wine. Take forty-eight ounces of potash, and sixteen of the above mentioned ashes, put them into six quarts of water, and the ley is made. Instead of the ashes an equal quantity of potash would probably do as well. To clean dirty colours, dilute some of this ley with four times its quantity of water, and rub the picture with it; then wash it with river water; and when dry, give it a coat or two of varnish. In order to take off a varnish, wash it with the above mentioned ley, then with water, and then lift it off the substance on which it was with any iron instrument.

VARPA, an island near the north-east coast of Sumatra, about thirty miles in circumference. Long. 103. 25. E. Lat. 0. 36. S.

VARRO, Marcus Terentius, a very learned and very miscellaneous writer, was born at Rome about the year 116
before the Christian era. He received what was then con-
sidered as the best education that could be obtained. Hav-
ing studied at Rome under Stilo, he proceeded to Athens,
and became the disciple of Antiochus, an Academic philo-
sopher. Returning to his native city, he began to take
some share in the business of the forum, but he does no
appear to have acquired much reputation as an orator. H
successively filled the office of triumvir, and tribune o
the people. When he was about forty-nine years of age
Pompey entrusted him with the command of a Greek fleet
employed in the war against the pirates. In a naval en
gagement which took place near the coast of Cilicia, h
acquitted himself with so much courage, that he was th
first that boarded one of the enemy's ships; and in honou
of this exploit, Pompey presented him with a rostral crow
For some time he acted as governor of Cilicia, apparentl
by virtue of an extraordinary appointment.

During the civil war which ensued, Varro adhered t
Pompey, and was employed as his lieutenant in farth
Spain. He was however advanced in years, and, accor
ing to Cæsar's account, was disposed to follow the tur
of fortune. The affairs of his own party having assume
a more promising aspect, he pursued measures of great
decision; and having embodied two legions, with thir
irregular cohorts, he made vigorous preparations for d
fending the province, but the speedy approach of Cæs
rendered all his plans abortive. One of his legions revolte
and the inhabitants evinced no disposition to make the qua
rel their own. Varro now adopted the resolution of marc
ing towards Italy; but finding that this attempt was i
practicable, he offered to deliver the remaining legion
any one whom the victorious general should nomina
Having accordingly delivered it to Sextus Cæsar, he p
sented himself to Julius Cæsar at Corduba, and made
surrender of all his treasure, ships, and stores. After t
unfortunate termination of his military services, he appe
to have devoted himself with great ardour and perseveran
to the pursuits of literature; and, as his life was exten
beyond the usual term, he produced a great number
works, and on a great variety of subjects. He cultiva
a particular intimacy with Cicero, who inscribed to him
Academica, as he inscribed to Cicero a portion of his tr
tise "De Lingua Latina."

When Cæsar returned to Rome after having subd
all his enemies, Varro entertained some apprehension
his personal safety, and thought it prudent to withd
from the city; but his fears were soon removed, and t
hostility was at length converted into friendship. Cæ
committed to him the charge of forming and superinte
ing a public library; a charge for which he was emine
qualified by his very extensive and variegated learn
After the death of this ruler of the world, he was ag
exposed to danger: he was included in the same proscrip
which proved fatal to his friend Cicero; but, even on
occasion, his good fortune did not desert him. His wea
as well as his political connexions, must have contrib
to mark him for destruction. He was sheltered and c
cealed by Calenus, and his name was at length erased f
the list of the proscribed. He was the possessor of sev
villas; and in the mean time one of these had been se
and plundered by Antony. The loss of his valuabl
brary, including some of his own writings, was one of
contingencies to which he was exposed at this unha
crisis. He however survived for many years, and conti
his studies with unabated ardour. At the age of seve
eight, as we learn from Aulus Gellius, he had comp
490 books. According to Pliny, he still continued to v
at the age of eighty-eight. His death is referred to
year 27 B.C.; and, according to the computation from
date and the supposed date of his birth, he must hav
tained the age of eighty-nine. It is not however

pr able that he may have exceeded this age by a few ye s.

arro has very frequently been described as the most lea ed of the Romans; and it has already been stated tha he wrote on an immense variety of subjects.[1] His wo s were partly in prose, and partly in verse. One of the , a Menippean satire, consisted of an intermixture of erse with prose, of Greek with Latin.[2] Some of them rel ed to grammar and rhetoric, others to history and philos hy, others again to politics and theology. He seems ind d to have embraced almost every topic of human specul ion. But of all these treasures of ancient learning, it is eply to be regretted that only a very inconsiderable ren ant has escaped the ravages of time. Of his twenty-fou books "De Lingua Latina," the first three have all per ned except a few inconsiderable fragments. The fourth, fift and sixth, relating to the origin of Latin words, and ins bed to Cicero, and the seventh, eighth, and ninth, rel ng to the analogy of the language, are however preser d, though not without some mutilations. Of the other boo s, scarcely a vestige remains. Even in this mutilated sta the work is both curious and valuable. His editor Sca ger has however shewn that his etymologies are not unfre ently erroneous; and another very learned critic, Salma us, has remarked that his reluctance to admit Greek der ations often leads him very far astray.

s three books "De Re Rustica," have reached us in a b ter condition. It appears from the exordium, that he un took the composition of this work at the age of eighty; and hat his wife Fundania, to whom it is addressed, had pu ased a demesne which she wished him to manag n the most advantageous manner. Some inconsiderabl fragments of his other works, in prose and verse, hav been preserved, and have been collected with due car

f the work "De Lingua Latina," an edition, consid ed as the first, is in quarto, without place or date, but sup sed to have been printed at Rome by G. Lauer, about the ear 1471. The editor was Pomponius Lætus. There are ther three very early editions, likewise without dates, but onjectured to have been printed, the first at Venice abo 1472, the second in the same city in 1474, and the thi at Rome about the same time. The first two are in qua o, the third is in folio. After this period, the work was ins ed in various collections of the Latin grammarians. Se al editions of it bear the name of Michael Bentinus. On of them is that of Paris, 1530, 8vo. This edition like ise contains the spurious *Origines* ascribed to Cato. An lition was publised by Antonius Augustinus, afterwards arc ishop of Tarragona, Romae, 1554, 8vo. The same edi n, which contains marginal emendations, but no comme ary, is generally to be found with the date of 1557, an t then includes several additions; at the beginning of the olume, "Dubia et Varia," "Doctorum Virorum Nomi qui hujus libri emendationi operam dederunt," and mo than two pages of *Emendata;* and at the end, seventy-tw nnumbered leaves, occupied with various indices. This edi n of Varro was reprinted among the works of the editor ugustini Opera, tom. vii. p. 425–524. The next editio vas that of Vertranius Maurus, Lugd. 1563, 8vo. It wa followed by the very elaborate and valuable edition of seph Scaliger, Paris. 1565, 8vo. And soon afterwards app red "Adriani Turnebi Commentarii et Emendationes in ros Varronis de Lingua Latina." Paris. 1566, 8vo. Th was a posthumous work, and laboured under the usual dis vantages of such publications. Here we must not overlook another learned labour, "Ad M. Ter. Varronis Assertiones Analogiae Sermonis Latini, Appendix Henrici Stephani." Exc. H. Stephanus, 1591, 8vo. An edition of Varro's work was published by Scioppius, Ingolstadii, 1605, 8vo. Another separate edition appeared after a very long interval, Biponti, 1788, 2 tom. 8vo. This very useful edition, which also includes the fragments of Varro's works, is illustrated with the notes of Augustinus, Turnebus, Scaliger, and Popma. It was followed by the critical edition of L. Spengel, Berolini, 1826, 8vo. And last of all appeared "M. Terentii Varronis de Lingua Latina librorum quae supersunt, emendata et annotata a Carolo Odofredo Muellero." Lipsiae, 1833, 8vo. This is an edition of no small value; and we add, with much regret, that the editor has been prematurely arrested in the midst of a very distinguished career. He died at Athens on the first of August 1840.

Varro's treatise "De Re Rustica" has been printed in the numerous editions of the "Scriptores Rei Rusticae." The earliest edition of this collection is supposed to be that printed by Jenson, Venet. 1472, fol. Two editions issued from the Aldine press in 1514 and 1533. A critical edition was published by Victorius, Lugd. 1541–2. It consists of four parts; of which the first three contain the text of the different writers, and the fourth, dated in 1542, bears the title of "Petri Victorii Explicationes suarum in Catonem, Varronem, Columellam Castigationum." This part, consisting of 144 pages, is sometimes to be found as a separate publication. And here we must likewise notice a learned work of Fulvius Ursinus, "Notæ ad M. Catonem, M. Varronem, L. Columellam de Re Rustica." Romae, 1587, 8vo. For a very elaborate and valuable edition of the "Scriptores Rei Rusticae," we are indebted to Gesner, Lipsiae, 1735, 2 tom. 4to. Lips. 1773–4, 2 tom. 4to. And another edition, described as the best, was more recently published by Schneider, Lips. 1794–7, 4 tom. 8vo. Of Varro's treatise on agriculture, an English translation was published by the Rev. T. Owen, Lond. 1800, 8vo.

Of both works of Varro there are several editions, and the earliest is that of Scaliger. Exc. H. Stephanus, 1569, 8vo. It was reprinted at Paris in 1573, 1581, and 1585. A collective edition of these two works, and the fragments of his other works, was published by Ausonius Popma, Lugd. Bat. 1601, 8vo. The same editor had previously made a collection of the Fragmenta, Franequerae, 1589, 8vo. Another edition of all his works was published not long afterwards, Durdrechti, 1619, 8vo. Some copies of the same edition exhibit the imprint of Amsterdam, 1623. (x.)

VARRO ATACINUS, Publius Terentius, a Latin poet, was born in the province of Narbonne in the year 82 before the Christian era. According to Jerom, he derived his *cognomen* from a village named Atace; but as we discover no other trace of such a village, the account of Porphyrion, that he derived it from the river Atace, appears more probable. His name indicates a Roman origin. Jerom likewise informs us that, at the age of thirty-five, he applied himself with great ardour to the study of Greek literature. Horace, Sat. i. 10. 46, alludes to him as an unsuccessful writer of satires:

> Hoc erat, experto frustra Varrone Atacino
> Atque quibusdam aliis, melius quod scribere possem,
> Inventore minor.

Wüllner concludes, that of a living poet Horace would not have spoken in such terms. Adopting Bentley's chronology, according to which, the satire that contains this passage was written in the year 37 B. C., he infers that Varro did not exceed the age of forty-five. The conjecture is not devoid of plausibility, but cannot be admitted as certain.

---

[1] ee Fabricii Bibliotheca Latina, tom i. p.124–132. edit. Ernesti, where very many of his lost works are enumerated.

[2] ee Casauboni de Satyrica Graecorum Poesi et Romanorum Satira libri duo, p. 258. Paris. 1605, 8vo.

[3] lis poetical fragments were very laboriously collected by R. Stephanus, Fragmenta Poetarum Veterum Latinorum, quorum Opera non ext , p. 305–364. Excudebat H. Stephanus, 1564, 8vo. These fragments were collected by the father, and digested by the son.

Varro Atacinus is extolled by several of the ancient writers. Velleius Paterculus classes him with Lucretius and Catullus. Quintilian mentions him as a poet who had acquired a name. He is likewise mentioned by Ovid, Propertius, and Statius.[1] Virgil adopted several of his verses with little or no alteration. It is however to be regretted that, with the exception of a few fragments, all his works have perished. These fragments are to be found in various collections, and, among the rest, in Wernsdorf's "Poetae Latini Minores." Altenburgi, 1788–99, 6 tom. 8vo. They are incorporated in Wüllner's learned dissertation on the life and writings of the author.[2] One of his works was a version of the Argonautica of Apollonius Rhodius; but from the fragments which remain, it does not appear to have been a close version. Another of his works, "Bellum Sequanicum," was an epic or historical poem in celebration of Cæsar's recent victories. A third was a metrical *Chorographia;* of which Ruhnkenius supposes his *Europa*, quoted by Festus, to have formed a part.[3] The rest of his works, so far as they are enumerated, consisted of elegies, satires, and epigrams. (x.)

VARSHAH, a town in the Affghan territories, in the province of Lahore, thirty-eight miles east from the Indus. Long. 71. 40. E. Lat. 31. 47. N.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious. In architecture, the appellation *vase* is also given to those ornaments placed on corniches, fochles, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice, as incense-pots, flower-pots, &c.

VASSAL, in our ancient customs, signified a tenant or feudatory; or person who vowed fidelity and homage to a lord, on account of some land, &c. held of him in fee; also a slave or servant, and especially a domestic of a prince. See Feudal System.

VATNA, or Fatsa, a small sea-port of Asia Minor, in the Black sea, at the end of a fine bay. It is now a poor village, with an old palace, and a large khan for the accommodation of merchants trading with the Crimea. It is ten miles south-east of Unieh.

VATTEL, Emmerich de, an eminent jurist, was the son of a protestant minister, and was born at Couret in the principality of Neuchâtel, in the month of April 1714. His academical studies he prosecuted at Basel and Geneva. During his early years, his favourite pursuit was philosophy; and having carefully examined the works of Leibnitz and Wolf, he exhibited a specimen of his talents for metaphysical investigation, by publishing a defence of Leibnitz's system against Crousaz. It was printed in 1741; and in the course of the same year, he repaired to Berlin in the hope of obtaining some public employment from the king; but this hope was so long deferred, that in 1743 he proceeded to Dresden with similar views, and experienced a very favourable reception from Count Bruhl. Some private affairs required his presence in his native country; but he returned to the court of Saxony in 1746, and obtained from the elector, Augustus the Third, the title of counsellor of embassy, accompanied with a pension. He was sent to Berne in the capacity of the elector's minister to that republic; and as his diplomatic functions did not require constant residence, he passed some portion of his time with his own family. Much of his leisure was devoted to literature and jurisprudence. Among other works, he published "Mélanges de Littérature, de Morale, et de Politique," and "Loisirs Philosophiques." But his best efforts were directed to a more elaborate work, on which his reputation is chiefly founded. It appeared under the title of "Droit des Gens; ou, Principes de la Loi Naturelle appliqués à la Conduite et aux Affaires des Nations et des Souverains." Neuchâtel, 1758, 2 tom. 4to. During the same year, having been recalled from Switzerland, he was employed in the cabinet of Dresden, and was soon afterwards honoured with the title of privy-counsellor. Although his constitution had originally been robust, his labours now became so intense as to exhaust his strength. Having tried the effects of relaxation and of his native air, he thought himself sufficiently recovered to resume his place in the cabinet. He accordingly returned to Dresden in 1766; but his renewed exertions soon produced a relapse, and he made another excursion to Neuchâtel, where he died on the 20th of December 1767, in the fifty-fourth year of his age. He left a son, who was recently a member of the council of that principality. The last of his literary labours was a work entitled, "Questions de Droit Naturel; ou, Observations sur le Traité du Droit de la Nature, par Wolf." Vattel's *Droit des Gens* continues to be studied and quoted as a book of authority. It has passed through many editions, and has been translated into various languages. An English translation was published in the year 1760.

VAUBAN, Sebastien le Prestre de, marshal of France, and the greatest engineer that country ever produced, was born in 1633. He displayed his knowledge of fortification in the course of many sieges, and his services were rewarded with the first military honours. He was made governor of Lisle in 1668, commissary-general of the fortifications of France in 1678, governor of the maritime parts of Flanders in 1689, and a marshal of France in 1703. He died in 1707, after having brought the arts of attacking and defending fortified places to a degree of perfection unknown before. His writings on these subjects are in great esteem.

VAUCLUSE, a department in the south-east division of France. It has been formed out of the ancient province of Avignon, of the county of Venassin, of the principality of Orange, and of a portion of Upper Provence. It extends in north latitude from 43° 41′ to 44° 26′, and in east longitude from 4° 34′ to 5° 38′. It is bounded on the north by the department of the Drome, on the east by that of the Lower Alps, on the south by the mouths of the Rhone, on the west by that of the Gard, and on a small part of the north-west by the Ardeche. Its extent is 1357 square miles. It comprehends four arrondisements, divided into twenty-two cantons, and those subdivided into 148 communes. In 1836 the population amounted to 246,071 persons, chiefly adhering to the Catholic church; but there are about 4000 Protestants, who have their own consistory to regulate their religious affairs. The inhabitants are of dark complexion, with penetrating eyes, spirited countenances, and are gay and lively in their appearance and manners. The face of the country in the whole of the eastern division is mountainous, and in the west is an extensive plain, which may be considered as a prolongation of the valley of the Rhone. The mountains in the eastern part may be viewed as a part of the Alps, or of spurs projected from that range. The highest point of these elevations is 6300 feet; but the main chain of the mountains can be scarcely estimated h her than from 2400 to 3000 feet. These mountains a all calcareous, and for the most part sterile; but the v leys between them have a soil, partly of sand or of clay, c ered with vegetable mould, which, when cultivated, is h hly productive. The best soil is in the vicinity of the r er Durance and of the Rhone, both of which streams d posit a rich muddy compost in their passage. The dis- t t between Carpentras and Avignon is almost covered w h a mixture of pebbles.

---

[1] With respect to the allusion of Statius, see Vossius de Historicis Latinis, p. 77.

[2] De P. Terentii Varronis Atacini Vita et Scriptis Commentatio. Scripsit Dr. Franciscus Wüllner. Monastfrii, 1829, 4to.

[3] Ruhnkenii Epistola Critica, ii. p. 286. Opuscula, tom. ii. p. 606.

The chief river is the Rhone, which enters the depart- nt from the Gard, and in it receives the waters of the L izon, the Aigues, the Meyne, the Lorgues, and the Du- r ce. The Durance, which flows from the Lower Alps, r eives the waters of the Jabron and of the Cavallon b ore it joins the Rhone. The Rhone is the only s eam that is navigable; but there are many small arti- fi al canals, which, though chiefly designed for the pur- p e of irrigation, are made available for the transport of h vy goods.

The climate is mild and healthy, but subject to great c nges. The trees in some seasons begin to blossom in Feb- r ry, but are often checked by severe cold and showers. T e husbandry is in an imperfect state; green crops and e n clover are not known, though lucerne is cultivated in s e parts. The chief grains are wheat, barley, rye, buck w eat, and maize. The whole growth of these is annually 6 000 quarters, which is not sufficient for the consumption o the inhabitants. The chief product for sale is wine. The o e trees yield some oil, which, with dried fruits and saf- f n, forms the chief object with which are exchanged the f foreign luxuries that are consumed. Silk worms are k t in some districts. The spinning and weaving of silk is t chief occupation of the inhabitants; and the weaving is s l to employ 2600 looms. These goods form a part of t exports, to which may be added madder, which is raised a l prepared for the dyers. Some springs of saline water f nish culinary salt. This department returns two members t the representative chamber. The capital is the city Avignon, with a population, in 1836, amounting to ,786.

VAUD or Waadt, a canton of Switzerland, in the west- most part of it, extending in north latitude from 46° 17′ t 47°5′, and in east longitude from 5°54′ to 7° 1′. It is bound- on the north by the canton and lake of Neuchâtel, on e east by Freyburg, on the south-east by Berne and Va- l s, on the south by the lake of Geneva, on the south-west Geneva, and on the west by the kingdom of France. It i 893 square geographical miles in extent, and is divided, der a new constitution introduced in 1831, into nineteen tricts, and subdivided into sixty circles, each of which nprehends either one or two, and a few three, communes parishes. The population in 1838 amounted to 183,582 rsons, of whom 175,000 are of French extraction, and eak that language; the remainder are of the German race. e prevalent religion is the Calvinistic, which possesses 7 parish churches; but in the district of Eschallans, the tholic worship is established over seven parishes, and it is erated in all other parts of the canton. By the new con- tution a simple democracy has been established. The gislative body consists of 184 deputies, who are chosen ery fifth year by all the inhabitants. The executive d administrative power is vested in a council of seven embers, selected from the members of the legislature, d appointed for six years. The judicial power is in a ate of transition. The military administration is in a ard, and it superintends the army, or rather militia, hich comprehends horse, foot, and artillery. The force ustered exceeds 24,000 men of all arms; and there are Lausanne and at Morges institutions for the education of ilitary students. The civil and moral education is con- cted in two academies, seven colleges, and 613 primary or parish schools. The annual revenue is derived from a land tax, a tax on patents or licenses to trade, a salt tax, a stamp tax, and some smaller items. It amounts to about one million francs, and the expenditure is nearly equal to it. The contribution to the general confederation is 59,280 francs, and the contingent of troops is fixed at 2964 men.

The face of the country in Vaud is generally undulating, with hills of moderate height and pleasing vales, but inclosed by chains of mountains, which in the south reach the highest point among the Alps. The greater part of the canton is the finest part of Switzerland. It presents to the view rich and beautiful plains, valleys varying in extent, gentle acclivities, verdant meadows, and delightful shores around the most wonderful lakes of this romantic division of Europe. It must however be acknowledged, that in these plains the soil is generally so heavy and difficult to work, and that in the more elevated spots so thinly covered with vegetable mould, that agriculture is by no means a profitable pursuit, and the inhabitants are mostly occupied in the breeding of cattle and the cultivation of the vine. The best wine, called Vaud wine or Ryff wine, is made between Vevay and Lausanne. Those called Vins de la Cote, made between the latter city and Geneva, are all white, while the best red wine is that made on the lake of Neuchâtel; but much is made in other districts. The growth of fruit is very extensive, and there are many extensive woods of chesnuts. Tobacco is raised of good quality, and in some parts hemp and flax. The main object of rural husbandry is however the breeding of cattle.

In the mountains of Aigle and Bex is the only salt spring in Switzerland. There is very little manufacturing industry, except for domestic utensils. Some leather is tanned, and a few cutlery articles are made at Vallorbe; and there is a little porcelain and some coarse pottery ware prepared in different districts. The commerce consists chiefly of the transport of French wares to the interior of Switzerland and to Germany, and in the export of wine and cheese, and of live cattle. The imports consist of French brandy, snuff, sugar, coffee, woollen and cotton cloths, iron, leather. The corn grown is seldom equal to the consumption, and in most seasons wheat and barley form a part of the import articles.

VAUDOIS, or Valdenses. See Waldenses.

VAULT, in *Architecture*, an arched roof, so contrived that the stones which form it sustain each other. Vaults are on many occasions to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VAVAO or Vavon, one of the Friendly islands, in the South Pacific ocean, seen by Perouse in 1787. It is nearly equal to the size of Tongataboo. Lat. of the western point 18. 34. S.

VAYPEN, a small town in the territories of the Cochin rajah, standing upon a narrow island of the same name, which extends along the coast thirteen miles, and is only one mile in breadth. Long. 76. 7. E. Lat. 9. 58. N.

VAZIRABAD, a town of the Seik territories, in the province of Lahore, situated on the east side of the Chinaub river, forty-seven miles N.N.W. from the city of Lahore. Long. 73. 28. E. Lat. 32. 25. N.

VEDAS, the sacred books of the Hindus. believed to be revealed by God, and called *immortal*. They are considered as the fountain of all knowledge human and divine, and are four in number; of which we have the following account in the first volume of the Asiatic Researches. The *Rigveda* consists of five sections; the *Yajurveda* of eighty-six; the *Samaveda* of a thousand; and the *At'harvaveda* of nine; with eleven hundred *sac'ha's*, or branches, in various divisions and subdivisions. The *Vedas* in truth are infinite; but have been long reduced to this number and order;

the principal part of them is that which explains the duties of man in a methodical arrangement; and in the fourth is a system of divine ordinances.

From these are reduced the four *Upavedas*, the first of which was delivered to mankind by Brahma, Indra, Dhanwantari, and five other deities; and it comprises the theory of disorders and medicines, with the practical methods of curing diseases. The second consists of music, invented for the purpose of raising the mind by devotion to the felicity of the Divine nature; the third treats of the fabrication and use of arms; and the fourth of *sixty-four* mechanical arts. Of however little value we may esteem the mechanical arts of the Hindus, and however despicable their theological system may really be, the *Upaveda*, which treats of diseases and the method of curing them, surely deserves to be studied by every European physician practising in India. There is indeed a great number of medical books in the Shanscrit language worthy of attention; for though the theories of their authors may be groundless and whimsical, they contain the names and descriptions of many Indian plants and minerals, with their uses, discovered by *experience*, in the cure of diseases.

VEERE, or Ter Veere, or by the English Campvere. This is a fortified town of the province of Brabant, and the kingdom of the Netherlands. It stands on the north side of the island of Walcheren, on a narrow channel near the mouth of the Scheldt, where two arms of that river meet. It has a fine arsenal, a handsome town-hall, and two churches. It was formerly the staple-town for the trade between Scotland and Holland; but its privileges, and much of its commerce, have been removed to Rotterdam. It has some large handsome dwelling-houses, but now not more than 1750 inhabitants.

VEGA CARPIO, Lope Felix de, a celebrated Spanish poet, was the son of Felix de Vega and Francisca Fernandez, who were both descended from honourable families, and lived in the neighbourhood of Madrid. In that metropolis he was born on the 25th November 1562. He was, according to his own expression, a poet from his cradle; and beginning to make verses before he had learned to write, he used to bribe his elder school-fellows with part of his breakfast, to commit to paper the lines which he had composed. Having lost his father while he was yet still a child, he engaged in a frolic very natural to a lively boy, and wandered with another lad to various parts of Spain, till, having spent their money, and being conducted before a magistrate at Segovia for offering to sell a few trinkets, they were sent home again to Madrid. Soon after this adventure, the young poet was taken under the protection of Geronimo Manrique, bishop of Avila, and began to distinguish himself by his dramatic compositions, which were received with great applause by the public, though their author had not yet completed his education; for, after this period, he became a member of the university of Alcala, where he devoted himself for four years to the study of philosophy. He was then engaged as secretary to the duke of Alva, and wrote his Arcadia in compliment to that patron, who is frequently mentioned in his occasional poems. He quitted that employment on his marriage with Isabel de Urbina, a lady (says his friend and biographer Perez de Montalvan) beautiful without artifice, and virtuous without affectation. His domestic happiness was soon interrupted by a painful incident. Having written some lively verses in ridicule of a person who had taken some injurious freedom with his character, he received a challenge in consequence of his wit; and happening, in the duel which ensued, to give his adversary a dangerous wound, he was obliged to fly from his family, and shelter himself in Valencia. There he resided a considerable time; but connubial affection recalled him to Madrid. His wife died in the year of his return. His affliction at this event led him to relinquish his favourite studies, and embark on board the Armada which was then preparing for the invasion of England. He had a brother who served in that fleet as a lieutenant; and being shot in an engagement with some Dutch vessels, his virtues were celebrated by the afflicted poet, whose heart was peculiarly alive to every generous affection. After the ill success of the Armada, the disconsolate Lope de Vega returned to Madrid, and became secretary to the marquis of Malpica, to whom he has addressed a grateful sonnet. From the service of this patron he passed into the household of the count of Lemos, whom he celebrates as an inimitable poet. He was once more induced to quit his attendance on the great, for the more inviting comforts of a married life. His second choice was Juana de Guardio, of noble birth and singular beauty. By this lady he had two children, a son who died in his infancy, and a daughter named Feliciana, who survived her father. The death of his little boy is said to have hastened that of his wife, whom he had the misfortune to lose in about seven years after his marriage. Having now experienced the precariousness of all human enjoyments, he devoted himself to a religious life, still continuing to produce an astonishing variety of poetical compositions. He undertook the very unpoetical employment of secretary to the Inquisition, and shortly afterwards entered into holy orders. In 1609 he became a kind of honorary member of the brotherhood of St. Francis. His talents procured him many unsolicited honours. Pope Urban VIII. sent him the cross of Malta, with a diploma of Doctor in Divinity, and appointed him to a place of profit in the Apostolic Chamber. He had dedicated his Corona Tragica (a long poem on the fate of Mary queen of Scots) to that learned pontiff. In his seventy-third year he felt the approaches of death, and prepared himself for it with the utmost composure and devotion. His last hours were attended by many of his intimate friends, and particularly his chief patron the duke of Sessa, whom he had made his executor; leaving him the care of his daughter Feliciana, and of his various manuscripts. The manner in which he took leave of those he loved was most tender and affecting. He remarked to his friend Montalvan, that true fame consisted in being good; and that he would willingly exchange all the applauses he had received to add a single deed of virtue to the actions of his life. Having given his dying benediction to his daughter, and performed the last ceremonies of his religion, he expired on the 26th August 1635. The number of his works is immense, but there is no complete and uniform edition. Fr. Cerda y Rico superintended a "Colecion de las Obras sueltas, assi en prosa como en verso." Madrid, 1776–9, 21 tom. 4to. This collection does not include his comedies, which would occupy a much larger number of volumes.[1]

---

[1] See the elegant and tasteful work of Lord Holland, Some Account of the Lives and Writings of Lope Felix de Vega Carpio and Guillen de Castro. Lond. 1817, 2 vols. 8vo. This Life of Lope de Vega was separately published in the year 1806.

VEGETABLE PHYSIOLOGY.

I the Article on the Anatomy of Vegetables, a view h s been given of the organography of plants, or the struct e and forms of vegetables through their several gradat ns from the seed to the perfect plant. We now proceed t consider the functions which the different organs of veg tables perform, the description of which constitutes what i termed the Physiology of Plants.

In a subject of such extent, and concerning which so ich diversity of opinion prevails, we must bespeak the i lulgence of our readers, not only for the imperfections l t for the errors into which we may fall. From the nar w limits within which we are necessarily circumscribed, are constrained to give rather the results than the de ls of experiments; to avoid all discussion of disputable ints; to reject many practical illustrations and much his ical narration. Neither have we room to enlarge on the neral distinctions between plants and animals; on the portance of vegetables in the scale of being; their geo aphical distribution; the nature of their living power or ality; their sensibility, perceptivity, and many other pro rties which have been ascribed to them. The Articles nimal and Physical Geography will however furnish e necessary information on these particulars. Our pre nt aim will be confined to a general view of the leading and re important functions of the more perfect vegetables.

IAP. I.—OF THE GENERAL FUNCTIONS OF VEGETABLES.

Sect. I.—*Of the Germination of Seeds.*

In the article referred to we have detailed pretty fully e anatomy of seeds, and described particularly their tunics d the nucleus contained within them. This nucleus con ts of the organized parts, or embryo, and the inorganic tter destined to afford it nourishment. In its more com ete forms, this embryo consists of the radicle, the stem cauliculc, and the plumule. The stem, however, is often t distinguishable. When present, it connects the ra cle with the plumule; and the place of its junction with e radicle is denominated the *neck* of the embryo. In the ogress of evolution, the radicle descends to form the root, d the plumule rises and constitutes the first bud of the w plant.

Besides the organised parts just mentioned, there are hers called cotyledons, which derive their origin from the bryo. Many seeds have two cotyledons, and some more an two; others have only one, and some seeds have no tyledon. When present, the cotyledons exhibit different rms; and between them and the embryo, a vascular com unication is established, as may be seen in the dissection a bean, represented in Plate XXXIX. fig. 12. Besides ssels, the cotyledons are partly made up of cells, within hich the nutrient matter of the seed is contained. In me seeds, however, this matter is only partially contained the cotyledons; in others, as that of wheat, it is wholly ntained in a cellular tissue produced from the inner tunic. astly, the cotyledons of some seeds rise above the ground uring germination, and perform the function of leaves: others they continue beneath the soil. In all seeds their xistence is temporary, for they perish after having yield d their nutrient matter to the embryo.

This matter, called *albumen* by Grew and Gærtner, is a ecretion made by the vessels into the cells during the for ation of the seed; and, though itself inorganic, is contained in an organized tissue. It is of various colour and consistence in different seeds. Its bulk, compared with that of the organized parts, is, in some seeds, very small; in others very large.

Such is a brief notice of the more important parts which construct the seed, and which it is necessary clearly to understand before we can properly appreciate the nature and effects of the actions that go on during its germination. In considering these actions, we have to inquire into the circumstances or conditions in which the seed requires to be placed—the agents which then act upon it—the change of quality and condition which these agents themselves suffer, and the effects which, in consequence, they produce in the seed—and, lastly, the physiological phenomena which thence arise, and terminate in those alterations of form and structure which constitute the evolution of the seed.

In general, seeds, when placed to grow, are buried more or less deeply in the earth, but this condition is not essential; for they readily shoot forth and display their forms, when confined in vessels of air. In whatever situation their germination is attempted, a certain temperature, and a certain portion of moisture, are necessary to its commencement; and the access of air is afterwards required to carry on the process. We have, therefore, to inquire into the operation of water, heat, and air, in commencing and carrying on the germination of the seed.

Water, in the first instance, penetrates the tunics of the seed apparently by simple attraction or imbibition; and the force with which this attraction is exerted is well illustrated in the experiments of Boyle and Hales. They filled strong bottles with dry beans and peas, over which water was poured, and the bottles were then closely stopped. As the seeds imbibed the water, they readily burst the bottles asunder; or, if small iron cylinders, closed by a plug, were employed, the plug was gradually raised by the expanding seeds, though pressed by a weight of nearly 200 lbs. It is by the exertion of such a force, that certain seeds, as those of the peach and apricot, are able, says Du Hamel, to burst open their stony envelope. This expansion from the imbibition of water occurs not only in seeds which retain the faculty of germinating, but in those also which have lost it. We must, therefore, regard this first step in germination as similar to the attraction of water by inanimate bodies. Accordingly, if, after water has been thus imbibed, air be excluded, the radicle never increases beyond a certain size; and, if the seed be kept wholly immersed in water at a temperature of 60°, decomposition of its substance ensues.

To this imbibition of water, a temperature above that of freezing is necessarily required; and, within a certain range, the rate of expansion will be more or less influenced by that of temperature. Cold, however, does not destroy, but only suspends, the germinating faculty in seeds. Seeds have germinated after having been exposed for a short time to a temperature of —39° F.

When, by the combined operation of heat and moisture, the seed is brought into a condition fit for germination, then the presence of air is required. Many experiments were made by Boyle and others, to prove the necessity of air to germination; and since the composition of the atmosphere was made known, many more have been instituted to ascertain why the air is thus necessary, the nature of the changes it undergoes, the extent to which they proceed, and the manner in which they are accomplished. On all these points much information has been gained, and the results obtained are, in general, so precise, as to leave little doubt as to the nature and extent of the facts, whatever difference of opinion may exist as to the mode of their occurrence. We must refer those who desire full details on these subjects to the writings of Scheele, Cruickshank, Gough, De Saussure, Huber, and Senebier, &c. The results of their labours are given, more or less completely, in most of our chemical works, and are more fully detailed in Mr. Ellis's "Inquiries into the Changes induced on the Air by the Vegetation of Plants," &c. parts i. and ii.

From these results we learn, that atmospheric air is useful to germination, from containing oxygen gas; that by the germinating process, the oxygen gas of the air is changed into an equal bulk of carbonic acid gas; and that the azotic portion of the air remains unchanged in composition, and generally unaltered in volume.

The nature and extent of the change induced on the air being thus ascertained, we have next to inquire into the mode in which it is brought about, that is, how the carbonic acid is formed. Now, when the experiment is conducted in close vessels, no other substance, but the seed, is present that can afford carbon: and this fact, taken in connection with the circumstance that the seed actually contains carbon, and yields it, like other organized substances, to the atmosphere that surrounds it, authorises the conclusion, that, while the air supplies the oxygen, the seed yields the carbon by which the carbonic acid of germination is formed.

Granting, however, that carbon is afforded by the seed, and combines with the oxygen of the air, where, it may be asked, and in what manner, is this combination effected? A certain degree of moisture in the seed is necessary to enable it to yield its carbon; for, when perfectly dry, little or no reciprocal action goes on between the seed and the air. Neither does the living faculty of the seed seem necessary to this combination; for carbon is afforded by seeds when they are confined by vessels in azote or hydrogen gas, and even under actual decomposition. We may therefore regard the formation of carbonic acid, in the first stages of germination, as purely chemical, and as taking place either on the surface, or within the substance of the seed. Now, from the dense structure of the investing tunics, and the circumstance of the vessels of the seed being already filled with fluid, we see no way in which air can enter the seed, so as to act either on its organized or inorganic matter; and, consequently, we incline to the opinion, that the formation of carbonic acid takes place exterior to the tunics of the seed. Such, then, are the changes in composition which the air employed in germination suffers, and such appears to be the mode in which they are accomplished.

While these changes are produced in the air, others not less remarkable occur in the form and qualities of the seed itself; for not only are its organized parts gradually evolved, but its inorganic matter, besides being softened by the imbibed water, acquires, in many seeds, a sweetish taste. These facts, which had long been observed in the process of malting, were more distinctly ascertained by Cruickshank. He found that seeds of barley, when placed to grow in vessels, either of atmospheric air or of pure oxygen gas, acquired, in a few days, a sweetish taste, and were more or less completely converted into malt.

In what manner then, or by what agency must we suppose this change in the inorganic matter of the seed to be accomplished? This matter, though denominated albumen, does not resemble the albumen of chemists. In vegetable physiology, the term comprehends the whole inorganic matter of the seed, although that matter may contain no real albumen, but consist of several distinct substances, or "proximate principles," as they have been called. The principal ingredients of seeds, which afford nutrient matter to the embryo, are mucilage, starch, and sugar. For a full account of the chemical properties of these substances, we must refer to the writings of chemists; our limits permit only a very slight notice of them.

Mucilage—the soft and liquid state of gum—is inodorous and insipid; soluble in hot or cold water, but insoluble in alcohol. *Starch (fecula)* is obtained from the flour *(farina)* of the more nutritive seeds. It is also insipid and inodorous: insoluble in alcohol, and even in water, unless raised to the temperature of 160°. If heated to 180°, the solution then jellies, and, by evaporation, may be reduced to a substance closely resembling gum. *Sugar* exists abundantly in the juice and fruits of plants; but in seeds, it is formed chiefly during their germination. It is soluble both in hot and cold water, and also in alcohol. Other ingredients, as *gluten*, albumen, and oil, are found in particular seeds.

Of the "proximate principles" which contribute to vegetable nutrition, chemists have attempted to ascertain not only the elements, but the proportions in which they enter into the several compounds. All agree in making these elements to consist chiefly of carbon, hydrogen, and oxygen, and in some instances also of nitrogen; but the proportions assigned by different analysts for the same substance differ scarcely less than those allotted for the composition of the different substances.

From the ultimate analysis of these substances, we derive little aid in explaining the chemical changes which they undergo; and we must therefore recur to other modes of accounting for those alterations in their sensible qualities which germinating seeds exhibit. In the germination then of many seeds, the hard and insipid albumen is gradually reduced to a milky form, and acquires a sweetish taste; while the organized parts become, at the same time, softened and expanded, and prepared to take on those actions, and exhibit those specific forms, which constitute the development of the embryo. Now, the only agents which act simultaneously on the several parts of the seed, when this development occurs, are water, heat, and air; and, as far as we have been able to trace their operation, the changes produced in the seed must therefore arise, more or less, from the action of heat and moisture; or from the loss of carbon; or from some specific agency exerted directly by the oxygen gas of the air; or arising indirectly out of its conversion into carbonic gas; or from the combined operation of these several agents. Let us then examine their operation, both separately and conjointly, and try to discover the share which each exerts in the production of these changes.

It has been shown that neither heat alone, nor moisture alone, nor both united, are able to produce the development of the seed; but that these agents contribute to bring it into a proper state for being acted on by the air. In what manner, then, does the air act on the germinating seed? No direct effect can be ascribed to its nitrogen; for that gas neither suffers nor produces change in germination, and the process goes on perfectly well either in pure oxygen gas, or in gaseous mixtures which contain no portion of azote.

But oxygen gas is essential to germination, and by that process is uniformly converted into carbonic acid gas. This disappearance of oxygen has led to the belief, that while a part of it was converted into carbonic gas, another portion actually *combined* with the seed, and contributed to its development. But it is well ascertained, that oxygen gas, by its conversion into carbonic acid, suffers no change of volume; and as the bulk of that acid gas, produced in germination, equals exactly that of the oxygen which has disappeared, it follows, that no portion of the oxygen, lost by the air, combines with the seed, but really exists exterior to it in the form of carbonic acid gas. The only other source from which the seed, in the experiments referred it could derive oxygen, is from the decomposition of water; but germinating seeds, says M. de Saussure, emit neither hydrogen nor oxygen, but only convert the oxygen gas of the air into an equal bulk of carbonic acid gas. It seems therefore, to be quite certain that the changes produced in the germinating seed cannot arise from the combination of oxygen.

Neither, in conformity to the opinion held by some, that the mucilage of the seed becomes sugar by losing a part of its carbon, can we ascribe the change of quality in the seed to the loss of that substance; for the portion of the carbon given off by the germinating seed is exceedingly small, and we have no evidence that it is afforded by its mucilaginous matter. The chemical change, by which mucilage is converted into sugar, takes place also in circumstances where there is no reason to ascribe it to the loss of carbon.

That the combined action of heat and moisture will produce on the *fecula* of seeds changes analogous to those which occur in germination, has been long known. Dr. Irvine long since remarked, that the farinaceous matter of seeds could thus be rendered sweet. Hence, distillers, says he, often mix not only grain imperfectly malted, but raw meal, with their malt; and the whole being then mixed with water, and submitted to distillation, becomes sweet, and forms wines and spirits. M. Fourcroy and M. Vauquelin obtained sugar and alcohol from bruised unmalted barley, by the combined use of water and heat; and Dr. Thomson has remarked, that the wort made from raw grain is nearly as sweet as from that which has been malted. In the experiments of M. Kirchoff and others, starch was converted into sugar by thirty-six hours boiling in four times its weight of water; and, from some later trials, it would seem that saw-dust and other vegetable matters, as linen rags, may, by a similar process, be made to experience a like conversion. From these experiments we learn, that the conversion of the *fecula* of seeds into sugar is an operation purely chemical, effected by the combined and continued action of heat and water; and since, in germination, the albumen of the seed is made to undergo a similar chemical change, under the varied operation of the same agents, may we not presume that it is accomplished in a manner somewhat similar?

When, by germination, the albumen of the seed has been thus changed from a solid and tasteless, to a fluid and sweetish substance, it is brought into a condition fit for the nutrition of the embryo. For this purpose, it is taken up, absorbed from the cells in which it had been deposited, and conveyed to the neck of the embryo, where a part of it is carried downward to feed the radicle, and another part upward to nourish the plume.

Connected with the structure that determines the course which the nutrient matter takes on reaching the neck of the embryo, appears to be that tendency in the plumule and radicle to pursue opposite directions, in whatever position or circumstances the seed be placed to grow. These tendencies have been ascribed to the action of light on the plume, and of earth on the radicle: but the radicle equally descends, although no earth be present, and the plumule rises, although light be excluded. Others have attributed the descent of the radicle to the greater weight of its sap, and the ascent of the plumule to the lighter condition of that fluid: but there is no evidence that, in these parts respectively, any such difference of sap exists. More lately, it has been supposed that gravitation acted in causing the descent of the radicle; and attempts have been made to counteract this by force, by keeping seeds, during their evolution, in continued motion on vertical or horizontal wheels: but the results obtained seem only to prove, that, in such circumstances, the radicle and plumule pursue, as usual, opposite directions, without affording any reason, why, in natural growth, the one always rises and the other descends. It is worthy of remark, that this tendency to descend exists only in the primary radicle or tap-root: for the lateral shoots which it puts forth extend themselves, says Du Hamel, nearly horizontally. In like manner, the rootlets that spring from the extremity of a cutting descend perpendicularly, while those that issue from its sides proceed horizontally. We may observe a corresponding peculiarity in the plumule and its productions. It is very singular, continues this writer, that a tree which springs from a seed raises its stem very straight: it is the same with a cutting taken from a straight stem; but a cutting taken from a lateral branch, or the bent shoot of a tree, bends much in its growth, especially if its wood be of a hard nature.

Both the radicle and plumule, as they receive nutriment, increase in all their dimensions; that is, both in length and breadth. The elongation of the radicle, according to Du Hamel, is produced only by the addition of new matter to its extremity, an opinion which the observations of Mr. Knight confirm. In the more succulent plumule, Du Hamel has shown, by satisfactory experiments, that elongation is produced by an extension of parts already formed, as well as by the addition of new particles; but this extension is not observed when the new parts have acquired a certain degree of hardness. In their diametral growth, it is probable that both the radicle and plumule experience, in their tender state, some degree of expansion from the motion of their contained fluids, as well as from the addition of new matter to their exterior surface.

In this brief account of germination, we have supposed the process to be carried on in closed glass vessels, in which the progress of evolution can be observed, the agents concerned in carrying it on made known, and their action, to a certain extent, appreciated. In such vessels the development of the seed can be continued until all the nutrient matter is exhausted, and the organized parts assume their peculiar forms, and execute their appropriate functions. If indeed water and air be duly supplied, the seeds of various herbs will grow and produce flowers and fruits without coming in contact with earth, as M. Bonnet ascertained; and in other experiments of Du Hamel, the seeds of different trees, which had been made to germinate on wet sponges, and had their roots afterwards set in bottles so as to be in contact with water, continued to vegetate for several years, and produced annually new leaves, bark, and wood, by the aid of water alone; so that, "without attempting to explain how the parts of this fluid become solid, it is certain," says this excellent writer, "that water is able to furnish the nourishment necessary to plants." For a description of the daily appearances exhibited in the evolution of several kinds of seeds, we must refer to our former article.

In ordinary germination, however, by the time the nutrient matter of the seed is exhausted, the radicle has sent forth rootlets through the soil, which at once serve to fix the plant in its place, and to draw from the earth fresh materials to sustain its growth. These materials, as will afterwards be shown, undergo certain changes in the young leaves, which have now sprung forth from the plumule, and in part execute the function of cotyledons. The cotyledons, if they have risen above the surface, now fade and fall; if they have remained beneath it, they decay and perish. In addition to water, heat, and air, the only agents required to carry on the germination of the seed, light now becomes necessary to give perfection to the plant; and its operation in bestowing colour and other peculiar properties on plants will be more particularly noticed hereafter. In this account of germination, we have given attention chiefly to the physical phenomena which it exhibits, reserving what we have to say of the seed, as a living body, to another occasion.

Sect. II.—*Of the Vegetation of Plants.*

Art. I.—*Of Soils, and of the Food of Plants.*

The plant, like the seed from which it sprang, is constructed of two elementary systems, denominated vessels and cells. For a detailed account of these, and of the opinions held concerning them, we must refer to our former article. By these systems, variously blended and combined, the several textures, denominated Cuticle, Bark, Wood, and Pith, are composed. The structure of these textures, as they occur in different varieties of herbs and trees, has likewise been described in that article.

Though the vessels of plants differ in form and structure, yet, with regard to use, they appear to be but of two kinds; those, namely, which receive and convey the common sap or lymph, and are named, therefore, Sap or Lymphatic Vessels; and those which contain and convey the juices proper to each species of plant, and are therefore denominated Proper Vessels. In trees, the sap-vessels are found chiefly in the wood, and the proper vessels in the bark; but in many herbs and in palms, both kinds of vessels are associated together through the entire stem. Whether they occupy distinct places in the vegetable, or are associated together, their functions are respectively the same; the sap-vessels being always employed in raising the sap upward, and the proper vessels in conducting its descent.

In all parts of plants, the vessels are in contact with cells, which serve sometimes the purpose of a connecting medium; sometimes to fill up vacuities or augment the bulk of parts; and sometimes as receptacles for various secretions. Between the vessels and cells a vascular communication exists, so that matter deposited at one time in the cells of the plant, may, at another, be taken up and again mixed with the fluids, as occurs in the germinating seed; and these functions of internal secretion and absorption seem to be performed, in plants, as well as in seeds, by the alternate exercise of the same vessels, acting at different times and under different circumstances.

Although, as we have seen, plants not only grow, but produce flowers and fruits without the aid of soil, yet, in ordinary circumstances, they draw the materials of their food from the earth. In an inquiry, therefore, into the nutrition and growth of plants, we have to consider the nature and properties of soils, which afford them habitation and nutriment—the absorption of this nutriment and its conveyance through the vessels—the changes of quality which it experiences in its course, so as to fit it for nutrition—the agents required to effect these changes, and the mode in which they act—and, lastly, the manner in which this nutrient matter, after having undergone its destined changes, is applied to nourish and augment the plant.

The soils in which plants grow are composed of organized and inorganic matters in various proportions. Of inorganic substances, the earths which prevail most are silica, alumina, and lime. With these earths, magnesia and certain metallic oxides, particularly that of iron, are often to be found. To these we may add alkaline matter, and animal and vegetable substances in different stages of decomposition and mixture. According to the proportions in which these mineral and organized remains are present and blended together, the soil will vary greatly in texture, in its property of retaining heat and moisture, and in its degree of fertility. To say, however, what mixture of substances constitutes the most perfect soil would be very difficult: for not only does climate greatly modify the natural condition of soils, but plants themselves exhibit the greatest diversity of choice or liking in this respect. Hence it is, that the soil and climate best suited to one plant, are ill adapted or unsuited to another; and that every part of the earth's surface, in which heat and moisture sufficient to sustain vegetation are present, is more or less clothed with its appropriate species of plants.

In considering physiologically the *uses* which the different ingredients of soils serve in vegetation, we must bear in mind that certain chemical elements seem essential to the constitution of vegetable matter; while others, though present and highly useful, are not so indispensably necessary. Thus, the vegetable substances, gum, starch, and sugar, are composed essentially of oxygen, hydrogen, and carbon; and woody fibre, when freed from all adventitious matter, is found to be composed of the same elements, united nearly in the same proportions. Now, considering woody fibre as the basis of the vegetable organs, and as formed, in germination, directly from the *fecula* of the seed, and probably the water in which it is dissolved, we may presume, that the elements which thus compose fecula, water and woody fibre, are the true constituents of vegetable matter.

In certain kinds of vegetable matter, which approximate to animal substance, nitrogen is a necessary ingredient. In other kinds, the vegetable substance partakes largely of the earthy materials of the soil. Hence lime and silica are abundant in certain plants; but as such substances can enter plants only in a state of solution, the earths met with in vegetables may not, says De Saussure, depend so much on those which constitute the basis of the soil, as on those held in solution by the water which it contains. Some have even supposed that the earths may be formed or generated in plants by the vegetative process; but the facts alleged in support of this opinion are not sufficiently precise. While, therefore, it is admitted, that earths are carried into plants, and, in certain tribes, enter largely into the composition of some of their textures, we have no evidence that they contribute directly to nutrition, or form an essential element in the composition of vegetable matter. Their use in affording station or habitation to vegetables is sufficiently obvious; and the temperature and moisture of the soil will also depend much on their kinds, proportions, and intermixture.

Together with the earths, chemical analysis shows, that sulphur, phosphorus, some metallic oxides, and particularly alkaline matter, exist in plants. Certain saline substances seem indeed necessary to vegetation. Marine plants languish in a soil destitute of common salt; and it is well known, that potash forms a large portion of the incombustible matter of land vegetables, and is especially abundant in the leaves. De Saussure found phosphate of lime in every plant he analysed. Certain plants throve well only in soils containing nitrates of lime or potash; and sulphate of lime or gypsum accelerated much the growth of lucerne and trefoil. These saline ingredients are highly useful, and the alkalis, in particular, seem necessary to the due perfection of the vegetative process; but, as the elements of these substances do not form a necessary constituent of the vegetable fibre, they cannot be considered as an essential part of the food of plants. Perhaps they may be regarded as condiments which aid in the process of assimilation; and, as will appear, they are otherwise highly useful in the vegetable economy.

With regard to the organized remains, which form so large a portion of the most fertile soils, they are not only soluble in water, like the other ingredients, but are composed of the same elements as vegetable substance. M. de Saussure found pure vegetable mould to yield, by distillation, products similar to those of the undecayed wood from which it had been formed, differing chiefly from it by containing a larger proportion of charcoal and some azote. Water dissolved a portion of this mould; and when deprived of this soluble portion, the residue, though unaltered in appearance, did not support the growth of plants so well as before. The part thus dissolved by water exhibited the properties of *extractive*,—a principle found in the sap, and especially in the bark of plants. Hence it appears, that de- ved vegetable matter, and the same may be said of ani- l remains, is not only conveyed into plants, but, being med of the same elements as the living plant, may be ceived to furnish materials necessary to its growth.

But in all soils adapted to vegetation, water is a neces- y ingredient, whether it be regarded merely as a vehicle the conveyance of other substances, or as itself forming ortion of the food of plants. To the experiments of Van lmont, Boyle, Bonnet, Du Hamel, and Braconnot, tending prove that water alone affords nutriment to plants, it has en objected, that the water which they employed, though parently pure, held in solution both earthy and saline tters; but, unless we suppose these matters convertible o oxygen, hydrogen, and carbon—the only essential ele- nts of vegetables—the presence of these earths and salts in water could not supply the elements required for the pro- ction of vegetable matter. If, on the other hand, with Hamel and De Saussure, we suppose water, though not composed, to lose its fluidity, and become fixed in vege- les, then we have at once two of the elements of woody re, combined in that proportion which the experiments Gay Lussac and Thenard exhibit them as holding in the nposition of vegetable substance.

Of the source of the other element, carbon, it is not less ficult to speak. It is an ingredient of vegetable mould, d of the carbonic acid carried into plants with the sap, her in a free state, or in combination with alkaline mat- ; so that, by these means, it is pretty largely supplied plants. On the other hand, M. Hassenfratz endeavoured show, that plants which vegetated in the open air by the l of pure water, yielded, on analysis, less carbon than the eds or bulbs from which they had sprung. M. de Saus- re obtained similar results when he analysed plants that d grown in pure water, and in a place weakly illuminat- ; but when they grew under the direct influence of light, en the proportion of carbon in the plant nearly doubled at in the seed. This carbon he supposes to be de- ed from that decomposition of carbonic acid which is rried on by the leaves of plants growing in sunshine. lmitting this to be the fact, we may perhaps regard the rbon thus deposited in the leaf as contributing rather to e formation of the inflammable products of the plant, than undergoing *assimilation*, and being applied to the pro- ction of new vegetable substance. And hence, as will terwards be shown, plants which grow in darkness not ly contain less carbon than those which grow in light, but e at the same time destitute of those inflammable ingre- ents which plants growing in light possess.

Beside the earth and water, the air also has been sup- sed to furnish food to plants. That plants obtain mois- re from the air will not be denied; and in as far as water concerned in vegetable nutrition, the moisture thus ob- ined may contribute to vegetable growth. But they have so been supposed to derive carbon from the atmosphere, decomposing its carbonic acid. Since, however, the at- osphere contains less than $\frac{1}{1000}$th part of carbonic acid is, the portion of that gas decomposed by plants in the en air must, even in sunshine, be necessarily very small, d the quantity of carbon thus obtained is probably much ceeded by that continually given off by plants to unite ith the oxygen gas of the atmosphere, through every pe- od of active vegetation. M. de Crell, indeed, deeming e carbon that could be afforded by the atmosphere insuf- cient to account for the addition of that substance which ants receive during their growth, was led to suppose they ssessed the power of forming carbon by the aid of water, r, and light; and M. Braconnot has maintained that vege- bles find in pure water every thing necessary for them to similate; that mould and manures yield no nutriment; d that earths, alkalis, metals, sulphur, phosphorus, and charcoal, are developed from water, by the organic powers of plants assisted by solar light.

"But the experiments," says Sir Humphry Davy, "in which it is said that alkalies, metallic oxides, and earths, may be formed from air and water alone in processes of vegetation, have been always made in an inconclusive manner; for distilled water may contain both saline and metallic impregnations; and the free atmosphere almost constantly holds in mechanical suspension solid substances of various kinds. The conclusions of M. Braconnot," he adds, "are rendered of little avail in consequence of these circumstances. In the only case of vegetation in which the free atmosphere, in his experiments, was excluded, the seeds grew in white sand, which is stated to have been purified by washing in muriatic acid; but such a process was insufficient to deprive it of substances which might afford carbon, or various inflammable matters."

ART. II.—*Of the Course of the Sap, and the Causes of its Motion.*

In the warmer regions of the earth, the sap flows, in certain plants, through the whole year; but in more temperate climes the functions of vegetables are suspended during the winter season. Early in spring, however, it begins to rise in trees, and continues daily to ascend till it reaches the extremities of the branches. This sap is absorbed from the soil by the extremities of the capillary rootlets, or the spongioles, as they are called, and conveyed upwards through the vessels of the root to the trunk. In its ascent it rises only through the wood; for, at this early period, no sap is found in the bark, nor between it and the wood, nor in the pith. This rise of the sap occurs *before* the buds have shot forth into leaves; and as no outlet for its escape by transpiration then exists, it rises or falls in the vessels in which it is contained according to the temperature of the atmosphere. If at this period of its flow, its course, in certain trees, be intercepted, by piercing the vessels of the trunk in any part, it issues forth, and may be collected for examination. In this way the vine, the birch, and sugar-maple, yield sap, or *bleed*, as it is called, very abundantly. They bleed also from the extremity of a cut branch, if the experiment be made sufficiently late in the season, but still *before* the appearance of the leaves.

Early in February, before the sap began to flow, Dr. Walker made several incisions, at different heights, in a birch tree, in order to observe its motion. No sap was visible at the lowest incision in the trunk till the temperature of the atmosphere rose to 46° in the shade; after which, as the temperature augmented, the sap continued daily to rise. When the highest incision in the trunk, at the height of thirty feet, bled, the thermometer was at 52°; and when the tree bled, not only from the incisions in its trunk, but from every cut extremity of its branches, it was at 56°. During the whole experiment, when the temperature was nearly the same, the sap continued nearly stationary,—rising again, as the temperature rose, just like the fluid in a thermometer. To the cut extremity of a vine branch, Dr. Hales, in the bleeding season, cemented long glass tubes, so that he could readily observe the movements of the sap. Into these tubes it would rise many feet through the morning after the sun was up; but while in this rising state, if there was a cold wind, or the sun was clouded, the sap would immediately subside, at the rate of an inch in a minute, for several inches; but as soon as the sunbeams broke out again, the sap would immediately return to its rising state, just as any liquor in a thermometer rises and falls with the alternations of heat and cold.

To ascertain the force and velocity of the sap's motion at this season, Dr. Hales made many experiments. He found it to rise in glass tubes, at the rate, sometimes, of an inch in three minutes, and to attain the height of more than twenty feet. In other experiments, it exerted a force sufficient to sustain a column of mercury at the height of thirty-eight inches; a force, says he, five times greater than that of the blood in the crural artery of a horse. In the chief bleeding season, the sap continued to rise by night and by day, but more in the day, and most of all in the greatest heat of the day; and when the sun shone hot upon the vine, a continued series of air-bubbles rose through the sap, so as to make a large froth on its top.

Such are the phenomena exhibited by the rising sap *before* the appearance of the leaves: when they have shot forth, a great change is observed in its movements. It still, however, continues to rise through the trunk; but if the wood be now pierced, none of it flows out, as it did in the bleeding season. In the excellent experiment of Dr. Walker, already referred to, the birch tree continued to bleed from the 5th of March to the 24th of April, on which day it bled from every incision in its trunk, and every cut extremity of its branches. On the 30th of April, vernation or budding began, and the young leaves shot forth. As they advanced, the bleeding gradually lessened, till at length, on the 10th of May, when the leaves were fully expanded, all the incisions, says Dr. Walker, which had yielded sap so freely, were everywhere dry; and this, not from evaporation by the leaves, but from a general diffusion of the sap from the wood through the bark at that season. In conformity with these observations, Dr. Hales remarks, that, after the appearance of the leaves, the bark, which was before dry, and adhered to the wood, becomes lubricated with sap, and easily separates. Even after the bark has thus been brought to separate from the wood in a young tree full of sap, if all the leaves, says Du Hamel, be stripped off, the bark, in two days, will again adhere to the wood, and continue to do so through the winter. These facts distinctly prove, that after the leaves have sprung forth, the sap of plants is no longer confined to the wood, but finds its way into the bark; and we have next to trace its route into that texture.

M. De la Baisse and M. Bonnet traced the sap of plants from the extremities of the roots into the leaves and flowers; and when the plants were set in coloured liquors, the fluid was seen to pass from the vessels of the leaf into its cellular tissue, and the bark of the petiole afterwards to become tinged. The communication thus established between the wood and the bark, M. Bonnet considered to occur in the extreme ramifications of the leaf, where, as he supposed, the ligneous and cortical vessels mutually anastomose. In a plant of Euphorbia, set in a coloured liquor, Dr. Darwin observed the fluid to run along the inner ring of vessels in the petiole to the upper surface of the leaf; while on its under side, a white fluid was seen to return from the extremities of the same leaf, and to descend, by the exterior ring of vessels in the petiole, into the bark. In similar experiments on the apple branch, Mr. Knight followed the returning fluid through the bark, by the vessels of which it seemed to be conveyed to the roots. These facts show that the sap, which is observed in the bark, after the leaves have sprung forth, gets into that texture by passing through those organs.

The leaves, which thus form the organs of communication between the wood and the bark, not only vary the course of the sap, but greatly influence its motion. Before their appearance, no natural outlet for its escape existed, and it therefore rose, continued stationary, or fell in the same vessels, chiefly according to variations of temperature. But when the leaves are developed, a large portion of the sap, in its passage through them, is thrown off by transpiration, and the remainder is conveyed into the bark; so that, by these means, the vessels of the tree are emptied, and put into a condition to attract fresh portions of fluid. Hales accordingly found that amputated branches of trees, which were furnished with leaves, and set in glass tubes of water, attracted from fifteen to thirty ounces of water in the course of the day; while similar branches, from which the leaves had been stripped off, imbibed, in the same time and circumstances, not more than one ounce. In like manner, a growing vine, which was perspiring abundantly by its leaves, ceased at once to yield sap from its stem, when cut over *below* the leaves. He found also that amputated branches, when plunged in water, imbibed from the small end to the great end as well as in the opposite direction; that they imbibed also when deprived of their bark, but not when stripped of their leaves; and that they would imbibe water from their small cut extremity, while still attached to the trunk. Hence it appears, that, after the period of vernation, the flow of the sap is promoted chiefly by perspiration from the leaves; and, therefore, if the leaves be removed, or their perspiration counteracted by a cold and humid atmosphere, then, as Hales found by experiment, the attraction of fluid by the sap-vessels is proportionally diminished.

To find the force and velocity with which the sap moved in this more advanced stage of vegetation, Dr. Hales cemented branches of trees, furnished with leaves, in glass tubes filled with water, and then set the lower end of the tube in a vessel of mercury. As the water was attracted by the branch, the mercury rose into the tube, in one instance, to the height of twelve inches in seven minutes. When the mercury had reached its greatest height, it would hold to that height for several hours in a warm sunshine, which favoured perspiration from the leaves; but as the sun declined or set, perspiration decreased, and the mercury ceased to rise. So great at this season is the attractive force of the leaves, that if a notch be cut in the trunk of a tree through which the sap is rapidly flowing, yet will the notch remain dry; "because," says Hales, "the attraction of the perspiring leaves is much greater than the force of trusion from the column of water." By other experiments he ascertained, that, when once the motions of the sap have been brought under the dominion of the leaves, the sap-vessels of the root no longer possess the same power of forcing the sap upward, as they did in the *bleeding* season; but so long as the leaves throw off the sap, the roots more or less abundantly attract fresh supplies of it from the earth.

In these various motions of the sap, both before and after the bleeding season, Dr. Hales ascertained that the tree underwent no variation in its dimensions; yet, whenever it rained, the stem very sensibly dilated, and when the weather again became dry, it subsided as much. "This shows," he adds, "that the sap, in all stages of vegetation, is confined in its proper vessels, and does not confusedly pervade every interstice of the stem, as the rain does, and thereby dilate it." Du Hamel also noticed this alternate augmentation and diminution in the size of trees, under the different states of a humid and dry atmosphere.

Beside this perpendicular ascent, there is also, in certain circumstances, a *lateral* motion of the sap. Dr. Hales cut four large gaps in the branches of different trees, at several inches distance from each other. The cuts were carried down to the pith, and opposed, in position, to the four points of the compass. If the cut branches were then amputated and immersed in water, they imbibed that fluid by their extremities, but not so abundantly as before, and continued to give it off freely by their leaves; if they remained attached to the tree, after such gaps were made in them, both the leaves and fruit of the branch flourished as well as those on other branches of the same tree; proving, says Hales, a very free *lateral* passage of the sap, where the direct passage had been several times intercepted. In these gaps, no moisture could, at any time, be either seen or felt, notwithstanding much fluid was passing by, because the stem, above the gaps, was in a strongly attracting state to supply the great perspiration of the leaves. Mr. Knight made similar in sions on the opposite sides of apple branches during the w ter season; yet, through these branches, the sap flowed in pring, and pushed forth the buds as usual.

rom the facts stated above, it appears, that, *before* the pe od of vernation, temperature is the chief agent in prom ing the flow of the sap; and that, *after* that period, its pr ress is aided principally by perspiration from the leaves. T re must, however, exist in the plant itself some conditic or structure which favours the operation of these agents. A lifferent periods, different causes have been assigned for th ascent of the sap. It has been supposed to exist in the sta of vapour, and its ascent has been ascribed to its levity: ot rs have attributed its rise to some imagined action of th spiral vessels; others to fermentation, or to the mech ism of valves; and others to a power of contraction and dil ation in the vessels, or to capillary attraction. Of these all ed causes, the two last alone deserve particular notice. Tl t a contractile power, derived from a vital source, is not ne ssary to the motion of the sap in plants, seems certain fr the fact of the ready transmission of fluids through de vegetables. Even the dissevered particles of vegetal s, as the ashes of wood, were found by Hales capable of tracting water with a force nearly equal to living organi d structures. From these and other facts, he considered th rise of the sap to be produced by capillary attraction, ai l by temperature, and especially by perspiration from th eaves.

he force of capillary attraction, when thus aided by ev oration, is strikingly illustrated by an experiment of P essor Leslie. He found that the attractive force, exerted by he very fine pores of a thin hollow ball of earthenware, fr which water was continually evaporating, was more th sufficient to support a load of mercury, in a tube attached the ball, equal to that of 400 inches of water, or a colu of thirty-four feet of that fluid. He estimates the diam rs of the pores in the ball at the 10,000th part of an in , and supposes the pores in the leaves of plants to posse nearly the same dimensions.

lthough capillary attraction, when aided by perspiratic from the leaves, may exert great influence over the m on of the sap, it is yet probable that some power or pr erty, inherent in the vessel as a living organ, assists its ac n. The direct effect of heat in promoting the flow of th sap in the bleeding season, and of cold in retarding it, se s to be more connected with some living property in th vessels, than with their powers as simple capillary tubes. If is heat be supposed to dilate the vessels, it ought to ch k capillary action, and cold, by diminishing their diam rs, ought to increase it; but the results afforded are ex tly the reverse of these. "If a capillary tube," says D Thomson, "be taken of such a bore that a fluid will ris in it six inches; and if, after the fluid has risen to its gr test height, the tube be broken short three inches from th ottom, none of the liquid in the under half flows over.—B if we cut a plant, the *Euphorbia peplis*, for instance, in o places, so as to separate a portion of the stem from th est, the milky juice of that plant flows out at both ends so ompletely, that if afterwards we cut the portion of the st in the middle, no juice whatever appears. Now, the di eter of these vessels is so small, that, if it were to contir unaltered, the capillary attraction would be more than su ient to retain their contents, and consequently not a dr would flow out. Since, however, the whole liquid es pes, it must be driven out forcibly, and consequently th vessels must contract." From similar experiments, Du H el inferred that the proper juice is forced out by a co raction of the vessels that contain it.

u Petit Thouars believes that the expansion of the buds ar the extremities of the branches in spring is the first ca e of the movement in the sap. He ascertained, by ex riment, that the sap begins to move at the extremities of the branches before it stirs at the roots. Dutrochet brings forward his theory of galvanic currents to account for the flow of the sap. The fluids of plants, he says, are denser than those which surround them, and hence a galvanic action, or *endosmose*, takes place, by means of which the water of the soil is propelled into their system. These two theories may be combined, and we may suppose that, when the buds are developed in spring, the fluid which they contain increases in density by evaporation; thus leading to a flow of the thinner fluids upwards by endosmose, the motion being propagated through the whole plant down to the roots which attract the fluid from the soil.

From all that has been advanced relative to the flow of the sap, we may conclude that temperature, the development of buds and leaves, and the exhalation from them, endosmose, and probably some vital actions, may all conspire to promote this important vegetable function.

In addition to the general circulation of sap, there are also special motions of it, confined to particular parts, and partaking more of a vital nature, to which the names of *rotation* and *cyclosis* have been given. The first of these motions is met with in plants of low organization, but is not confined entirely to flowerless or cellular plants; while the latter occurs only in plants of a higher organization, although not limited exclusively to flowering species.

Rotation has been noticed chiefly in the genera *Chara* and *Nitella*, and consists of currents setting from joint to joint, flowing down one side, generally that next the axis, and returning up the other, without any membrane intervening to separate the opposing currents, and the motion in each cellule being independent of that in the cellules next to it. The motion occasionally intermits, and is rendered obvious by green granules of starchy or oily matter, which float in the fluid of the cellules, and are carried about by the currents. Some interesting observations have been made on these peculiar vital movements by Treviranus, Amici, Solly, Varley, and Slack, in the Annales des Sciences Naturelles, and the Transactions of the Society of Arts.

Cyclosis was discovered by Professor Schultz of Berlin in 1820, and consists of the motion of a fluid called *latex*, analogous, in many respects, to the blood of animals, and contained in peculiar vessels, to which the name of *cinenchyma* or *laticiferous* vessels has been given. These vessels consist of branched anastomosing tubes, lying in no definite position with respect to the rest of the tissue, and so thin and capillary in the young state as to be scarcely visible. They are expanded and contracted at intervals, and their sides are not parallel as in other vessels. They exist often in connection with spiral vessels. The latex is sometimes transparent and colourless, but in many cases it is opaque, and either milk-white, yellow, red, orange, or brown. Its colour is due to the presence of numerous minute globules, which are constantly agitated as if by a spontaneous motion, and appear to be alternately attracted and repelled by each other. The latex is looked upon as the proper juice of the plant. On exposure to the air it separates into a tenacious coagulum and a thin serum. The motion of the latex, or cyclosis, consists of currents, which are observed traversing the laticiferous vessels, and passing through the lateral connecting tubes or branches into the principal channels. These currents, which are rendered visible by the movement of the globules in the latex, follow no determinate course, but seem to be very irregular in their direction, some proceeding up, others down, some to the right, and others to the left; the motion occasionally stopping suddenly and then recommencing. The motion is checked by diminution of temperature, or by a wound in the vessels, and it is completely arrested by a strong electric shock.

Cyclosis has been observed in *Ficus elastica*, or the Indian rubber plant, *Chelidonium majus* or Celandine, *Alisma Plantago*, *Tradescantia*, &c.

For full particulars relative to these singular movements, the reader is referred to M. Schultz's paper, which will speedily be published in the Mémoires de l'Académie des Sciences.

Art. III.—*Of the Qualities of the Sap, and the Changes which it undergoes in the Leaves from the agency of the Air.*

Having said so much of the *motion* of the sap, and of the powers by which that motion is accomplished, let us next direct our attention to its *qualities.* If collected during the bleeding season, it is almost without taste, but sometimes a little sweet. It ordinarily yields, by evaporation, only a little mucilage; but that of the maple of Canada is said, by Du Hamel, to afford nearly 5 *per cent.* of sugar. The sap of the elm (*Ulmus campestris*) was examined by M. Vauquelin at successive periods of vegetation. In his first analysis he found 1039 parts of it to consist of

1027·904	water and volatile matter;
9·240	acetate of potass;
1·060	vegetable matter;
0·796	carbonate of lime.

At a later period, the vegetable matter was in greater quantity, and the saline ingredients had diminished; and, at a period still later, these changes were still more evident. Other saps were analysed, and found to possess similar ingredients; and some others in addition. The sap of the beech contained gallic acid and tannin; and that of the birch, sugar, and acetates of alumina, and lime. The sap of the vine, examined by Dr. Prout, resembled river water in appearance and specific gravity, but was sweetish to the taste. It yielded, by evaporation, a minute portion of *residuum*, consisting of a peculiar vegetable matter and carbonate of lime.

The increase of vegetable matter observed in the sap as the season advances, suggests the idea that it becomes mixed with matter previously deposited in the tree. This idea occurred to Malpighi, who considered the sap, as it rose through the vessels, to be partly deposited in the cells, where it underwent changes which fitted it for supplying the first nutriment to the young buds and tender leaves. A similar opinion was held by Darwin, who also supposed the sweet juices found in certain roots, and in the knots and stems of some of the grasses, to serve the same purpose. From finding the specific gravity of the sap to increase as it rose higher in the tree, and the alburnum of a tree, felled in winter, to be heavier than in other seasons, Mr. Knight also supposed a deposition of nutrient matter to be made in the alburnum, through the latter part of summer and autumn; so as to be ready to mix with the sap in the following spring, and afford nourishment to the buds and leaves. Hence, we may consider the young bud, like the embryo of the seed, to draw its first nutriment from matter previously secreted, and in part deposited in cells, and afterwards reabsorbed and applied to its destined use.

The bud, thus nourished in its early growth by the ascending sap, is more or less rapidly developed, and the tree soon becomes clothed with leaves. Of the changes in the *motion* of the sap when vernation occurs, we have already spoken, and have now to describe others which are effected in the *qualities* of the fluid. The first action of the leaves upon the sap is to throw off a large portion of it. The insensible perspiration of plants has been particularly investigated by Woodward and Hales, and by Bonnet and Guettard. Dr. Woodward found that a sprig of mint, weighing only 27 grains, imbibed, in seventy-seven days, 2558 grains of water: yet its weight was increased only 15 grains; and it must therefore have given off in that time 2543 grains of fluid. Hales calculated that a sun flower, the area of the surface of which above ground was equal to 5616 square inches, gave off, by perspiration, in a warm dry day, about 20 ounces of fluid. In a warm dry night, without dew, it exhaled only three ounces. When the dew was sensible, there was no perspiration; and when the dew was abundant, or the night wet, then the weight of the plant was increased. The more succulent leaves perspired more than those of firmer texture, and deciduous more than those of evergreens. In plants of the same species, and placed in similar circumstances, perspiration is proportional to the extent of perspiring surface: but in all plants, cold and humidity more or less diminish or entirely suspend this function.

The fluid thus perspired was collected by Hales as it issued from the leaves of various herbs and trees. The liquor in all was very clear, nor could he distinguish any difference in its taste. It had nearly the specific gravity of water, but when exposed to a hot sun it began sooner to putrify. Senebier evaporated the perspired fluid of a vine: the *residuum* consisted of minute portions of resinous and gummy matter, and of carbonate and sulphate of lime, which ingredients seemed to augment as vegetation proceeded.

By the loss of its more aqueous parts, the proportions of the remaining ingredients of the sap must be much changed. Grew, Malpighi, Du Hamel, and others, have pointed out the great differences produced in the consistence, colour, odour, and taste of the sap during its transmission through the leaves; differences peculiar to each species of plants, and which have obtained for the sap, at this stage of its movement, the appellation of Proper Juice. It is in this proper juice, says Du Hamel, that the narcotic power of the poppy, the corrosive quality of the fig, the diuretic virtue of the fir, and the purgative property of jalap, resides: and even the peculiar products obtained from the sugar cane and maple arise probably from the intermixture of the proper juice with the common sap: whence we may infer that the virtue of plants resides principally in their proper juice.

It is difficult to collect these juices in a pure state. Those which have been examined differ much in their chemical properties. In some of them, mucus is the predominant ingredient, and such juices are generally mild and nutritious. Of the milky juices some are mild, others hot and acrid. From the proper juice of Euphorbia, M. Chaptal obtained, by the agency of chlorine, a white precipitate, consisting of two parts resinous matter and one part woody fibre. The juice of the *carica papaya*, a tree that grows in Peru, yielded M. Vauquelin a substance very like the fibrine of animal matter. From other juices, gums, resins, turpentines, balsams, tannin, sugar, and various other products, have been obtained: so that, in their sensible qualities, these juices differ as much from each other as they do from the common sap; but all of them appear to contain a substance resembling in character the woody fibre.

That the difference of quality observed in the common sap and proper juices is effected chiefly in the leaves, seems now to be generally admitted. Some part of this difference is doubtless attributable to the concentration which these juices experience from the exhalation of so much water; but a much larger part is to be ascribed to the effects which result from the combined agency of light and air. That air is essential to the vegetative process, and that the leaves of plants more especially act on the air, are positions long since established by decisive evidence; but physiologists are not yet agreed as to the nature and extent of this action, nor, consequently, as to the mode and degree in which it affects the vegetable fluids. This discordance appears to us to have arisen partly from imperfect experiment, and partly also from blending together two actions performed by the leaves, which, in their nature, are quite distinct, and which, though they commonly go on together, may be easily separated, and the peculiar and specific results of each better observed and estimated.

In the ordinary circumstances of growth, plants are exposed at the same time to both light and air; and each agent exerts on them peculiar and specific effects. If deprived of air, when in a state of active vegetation, plants not only cease to grow, but soon die; but the exclusion of light is not followed by suspension of growth, and still less by death. Hence, in favourable circumstances as to heat and moisture, plants continue to vegetate even through the night; and are frequently seen to grow in situations from which light is wholly excluded. They then lose, however, many of their peculiar and more active properties; but they augment in size, and display their specific forms. Air, therefore, is essential to vegetation; but light, though necessary to the development of certain properties, is not essential to the growth of plants. It will be convenient to consider the functions of the leaves, first, in relation to air; and secondly, in relation to light.

The late Dr. Priestley led the way in pointing out the nature of the changes which the air suffers in vegetation; but from not clearly ascertaining, at that early period, the composition of the air he employed, nor the extent of change it suffered, nor being fully aware of all the circumstances which might vary his results. he arrived at contradictory conclusions as to the effects which vegetation ultimately produces in the air. On the whole. however, he considered the atmosphere, when vitiated by other processes, to be purified by the growth of plants. His illustrious contemporary, Scheele, by previously removing the carbonic acid from the foul air he employed, found that plants, by their vegetation, either in sunshine or in shade, constantly deteriorated the air. Similar results, as to the deterioration of the air, in ordinary vegetation, were obtained in many of the experiments of Ingenhousz, Senebier, Woodhouse, and De Saussure; and they have since been extended and confirmed by Mr. Ellis in the work already referred to. By these experiments, it is proved that plants, like the seeds from which they have sprung, require, in the atmosphere in which they are set to grow, the presence of oxygen gas; that, by their vegetation, they convert this gas into an equal bulk of carbonic acid gas; and that the azotic portion of the air, as well in volume as in composition, remains unaltered.

As the seed, in its germination, supplied carbon to unite with the oxygen of the atmosphere, so does the plant yield that element for the same purpose, during its vegetation. Most vegetable substances, either dead or living, solid or fluid, when placed in suitable circumstances as to heat and moisture, deteriorate the atmosphere by forming carbonic acid gas; and the experiments of Huber, Senebier, and De Saussure, show, also, that, when all the oxygen of the air has been consumed, they still yield carbon to unite with its other ingredient, so as to form carburetted azotic gas; or, if hydrogen gas has been employed instead of azote, then carburetted hydrogen is formed. Neither the living state of a plant, nor the presence of oxygen gas, is essential to the separation of carbon from vegetable matter; and we may, therefore, presume that its separation is owing not so much to any attractive force exerted by the gas employed, as to some spontaneous change in the vegetable compound itself, whereby its carbon is enabled to combine with the gases that surround it, in the order of its affinity for them. In low temperatures, or when the plant is very dry, its functions are more or less completely suspended, and the formation of carbonic acid is then proportionately reduced; while, on the contrary, a vigorous exercise of the vegetative powers gives rise to a corresponding production of that gas. In what state or form the carbon exists, at the moment of its combination with elastic fluids, is not yet known; but it is probably held in solution by water, and acquires and retains its elastic state, only while in union with a permanently elastic body. It may further be asked, in what part of the plant does this union of its carbon with the oxygen gas of the air take place, and in what manner is it accomplished? In the living plant, it is chiefly by the leaf that carbonic acid is formed. To discover the mode and place in which it occurs, we must take into view not merely the change produced in the air, but the structure of the living organ by which that change is effected; for it is only by combining a strict regard to anatomy with our chemical knowledge, that we can ever hope to arrive at true physiological conclusions, and avoid the crude and fanciful notions that have too often usurped their name.

The leaf, then, is formed of a vascular system, of cellular tissue, and of a cuticular covering that invests it on all sides. To this organ the sap is brought by vessels which spring from the alburnum or wood, and which, after forming several fasciculi in the petiole, proceed to the base of the leaf, and there, by their expansion and distribution, produce a minutely reticulated structure. With these sap-vessels, proper vessels are every where associated, which appear to communicate with the sap-vessels, and to convey into the inner bark the sap which they receive. Grew considered the vessels, which form the reticulations of the leaf, to be of the same size in every part, and never to inosculate or anastomose, except end to end, or mouth to mouth, after they have come to their final distribution. Malpighi, on the other hand, believed them to anastomose in every part: and, in regard to the minuter transverse fasciculi, given off from the longitudinal bundles, he has been followed by Dr. Todd Thomson, who, however, though he considers them as "distinct vessels, uniting with the longitudinal bundles in a singular manner," has never been able to determine "whether there is any opening directly into the longitudinal vessel on which the extremity of the transverse vessel is applied." It is during the course of the sap, through the two orders of vessels in the leaf, that it undergoes those changes in its properties which fit it for nutrition; but whether these changes are effected in the sap-vessels, or the proper vessels, or partly in both, has not yet been determined.

The minute network formed by the vessels is everywhere filled up with cellular tissue, constituting the parenchyma of the leaf. The cells of this tissue contain fluids derived from the neighbouring vessels, and are likewise the seat of the green colouring matter. There must, therefore, be a ready communication between the vessels and cells; and this many have supposed to be accomplished by the medium of pores in the sides both of the cells and vessels. But the best observers represent the cells as close cavities, having no visible communication with each other. Were we even to admit the existence of pores, we should find it difficult to conceive how the contents of the cells could be set in motion and transmitted through their own sides, and those of the vessels also, so as to be conveyed and deposited in the several parts where growth takes place, with all the regularity we actually observe. To us no other means occur of accomplishing these operations, consistently with the integrity of the cellular structure, than the exercise of those alternate functions of secretion and absorption, which, from so many other considerations, we have supposed to be carried on in every vegetating part of the plant.

The cuticular covering of the leaf is the organ through which, under different circumstances, the fluids that are exhaled and absorbed must pass; and through which also both light and air exert their peculiar action on the vegetable juices. The structure of this organ has excited particular attention, and the opinions held concerning it have been detailed in our former article. It is there described as being composed of a proper cuticle, beneath which is a vascular network, the vessels of which, springing from the larger fasciculi, form at various points an oval ring, from whence go off two or more radiating filaments, which terminate at the cuticle in an oval pore, more or less elongated. It is by the vascular filaments, which thus terminate at the pores of the cuticle, that the exhalation of fluids is held to be performed; and hence it is, that, in different plants, this function is more or less abundantly carried on, in proportion to the number of cuticular pores or stomata; and that plants, and parts of plants, which have but few pores, perspire little, and those that are destitute of pores not at all. Precisely the same coincidence between the number of stomata in leaves, and their power of absorbing fluids, has also been remarked; and M. Decandolle believes that the vascular pores, on the surfaces of the leaves and of porous stems, are the organs by which the functions both of exhalation and absorption are alternately carried on, according to the existing condition of dryness or humidity in the surrounding atmosphere.

Beside the function of exhalation, it has lately been maintained by Dr. Todd Thomson, who has bestowed great attention on the structure of the leaf, that the stomata are the organs by which the function of respiration in plants is performed. According to him, the pore is not a superficial aperture, but "a short cylindrical tube, penetrating completely through the cutis, and terminating in a cul de sac, which is impressed into a vesicle that appears to communicate with the oblong cells immediately beneath the cutis. But although the aperture penetrates the cutis, there is no opening through the epidermis, which, on the contrary, enters into the tubular part of the pore, and lines it throughout."[1] In different leaves, the form of the pore, of its short tube, and of the vesicle beneath, are said to vary; but the cuticle or epidermis dips down and lines the cavity in all. By the funnel-shaped pore above described, the air is said to be admitted into the vesicle situated beneath it: and as this vesicle probably communicates with the cuticular cells, which are in general filled with air, the aqueous contents of the cells that form the parenchyme of the leaf, are thus brought into immediate contact with the atmosphere.[2]

It can hardly, however, be admitted that the existence of stomata is indispensable to the production of that chemical change in the air which constitutes respiration; for, according to Decandolle and Rudolphi, the petals of flowers, the cuticle of fleshy fruits, the tunics of seeds, the stems and leaves of etiolated plants, most of the lower tribes of vegetables, and all roots and bulbs that grow beneath the soil, are alike destitute of stomata; and yet the united experience of Priestley, Scheele, Ingenhousz, and De Saussure, bears testimony that all these parts are capable of acting on the air like porous leaves. Dr. Thomson indeed states that some of the lower tribes of vegetables, and certain etiolated leaves, are really furnished with stomata: but even granting this to be the case, there still remain other parts of plants, which grow beneath the soil, and yet act upon the air, like porous parts that vegetate on the surface. Without denying, therefore, the probability that stomata may favour the exercise of the respiratory function, we are compelled to admit that surfaces, not yet discovered to have stomata, are capable of producing similar changes in the air.

But whether the air enter the stomata in order to be changed, or is merely changed at the surface of the plant; or whether, by some unknown means, it permeate the cuticle, cells, and vessels, so as to act directly on the fluids they contain; it seems certain that these fluids acquire the properties, which fit them for nutrition and growth, directly through the agency of the air. How, then, does the air act in producing such effects? No specific action can be ascribed to its azotic portion, since that gas is not essential in vegetable respiration; and when present, it neither suffers nor produces any known change. Neither can we suppose the effects produced to arise from the loss of carbon, for were it proved that this carbon is extracted directly from the juices contained in the vessels, rather than afforded by the fluids which they exhale, still the quantity given off is too minute to be considered as the cause of such remarkable changes; and it is more reasonable to believe that they proceed rather from something derived from the air, than from anything given off from the plant. They have accordingly been very generally ascribed to the *combination* of oxygen with the juices of the plant; this oxygen being partly supplied by the external air, and partly by the air contained in the spiral vessels of the plant.

ART. IV.—*Of the mode in which the Proper Juice is applied to the Purposes of Growth.*

It is only after the common sap has been duly changed in the leaf by the agency of the air that it is rendered fit for the formation of vegetable matter. For this purpose, it descends in the "proper vessels," which in trees are commonly situate in the bark. If at this period, therefore, a circular portion of that texture be cut away, the proper juice is seen to issue from the *upper* lip of the wound; but this soon ceases, and its accumulation in the vessels then forms an enlargement around that part. Sometimes the proper juices exude, and form concretions of a gummy, saccharine, or resinous nature on the surface of the bark, and sometimes they are effused into the sap-vessels or cells. Where the bark is young and succulent, the juices probably receive some further change in their descent; for such stems act on the air like leaves, and, in some species of plants, which are destitute of leaves, the functions of the leaves are performed by the stem alone. In ordinary trees, however, the bark is unable to form nutrient matter without the aid of the leaves, as an experiment of Hales distinctly shows. He removed circular portions of bark, half an inch in breadth, from a thriving branch of a pear tree, so as to leave several ringlets of bark, three quarters of an inch distant from each other. All these ringlets, except one, had a leaf-bearing bud on them, and all but this one swelled at their bottoms and grew; and the more leaves the bud produced, so much more did the bark on which it grew swell at the bottom, while the leafless ringlet did not swell or increase at all. From facts before stated, it also appears, that a portion of the nutrient matter that descends from the leaves is found in the alburnum, as well as in the bark; and this will be still more clearly shown when we come to treat of the regenerating powers of the alburnum.

In discoursing on the trunk of trees, it was stated that a layer of bark, called *liber*, and a circle of wood, named *alburnum*, are annually formed; and that between this liber and alburnum the new matter that adds to the bulk of the tree is deposited, and becomes organised. Malpighi believed the *liber* to form the new parts, and that these parts were afterwards converted into wood. Grew also considered the new wood to be formed by the bark, but not the liber to be converted into wood. Hales, on the other hand, supposed the new wood to be formed by the old; while others have held that both bark and wood contribute to form new matter. Are, then, the new layers which are annually adde to the tree formed by the bark, by the wood, or by both By various experiments, which we have not room to detail M. du Hamel endeavoured to shew, first, that the bark i able to form new wood, and that this power resides not i its outer layers, but in the part called *liber*; secondly, tha the *alburnum* is also able to produce new wood and bark but that this power is not possessed by the older and mor hardened vessels of the wood.

The process by which new vegetable matter is formed i trees is thus described by the same excellent writer. Whe a portion of bark has been removed from a tree, a glair m cilaginous fluid is first seen to flow from beneath the rem ning bark, or, in certain circumstances, from the alburnum. I liffers in appearance from the proper juice, and was name *cambium* by Grew. To observe the process more comp tely, Du Hamel enclosed the stems of young elms and c rry trees, from which portions of bark had been removed, in glass tubes, closed at each end by cement. For a few d s, the glass was obscured by vapour, which gradually d ppeared; so that it was then easy to see what passed w hin. At first, a small tubercle appeared beneath the u er lip of the wound, and one still smaller at the lower li After this, granules of gelatinous matter issued from th alburnum: they were isolated, and had no connection w the tubercles just mentioned; their colour was at first gr yish, but, in about twelve days, passed to a greenish tint. A these new parts continued to extend through the summ ; the tubercle from the upper lip of the wound enlarged gr tly, but that below, very little; so that it was principa y by the growth from above that the wound was healed. T bark of the cicatrice having been formed by the union of new productions from the upper and middle part of the w nd, was very rough, and in some places entirely wanting; b all the regenerated parts duly performed their appropr te functions, and the stems augmented so much as, in so e instances, to burst asunder the glass tubes that encl ed them.

---

[1] Thomson's Elements of Botany, vol. i. p. 614.

[2] Ibid. p. 622, 623.

While Du Hamel's experiments showed that new wood w not produced from the old, they did not prove that it w produced by liber. Accordingly, with the view of clearin up this matter, Mr. Knight instituted new experiments, b which he was led to adopt the idea, that wood is not the pr luce of bark, but is formed by matter sent down from th leaves, this matter forming both new wood and new bark.

Du Petit Thouars, from observing, in the Isle of France, w t takes place in the formation of the branches of *Draca a*, and other monocotyledonous plants, has come to the co clusion, that woody fibres are the prolongation of the b s or germs which are developed. He looks upon buds as n fact fixed embryos, which send roots downwards to fo new wood and bark, and shoots upwards to form new br nches. According to this theory, the young shoot may be egarded as the plumule, the pith as the cotyledon, and th fibres of the wood and bark as the roots. The cambi n he considers as useful in nourishing the bud roots. A important feature in this ingenious theory is, that it is ap icable both to exogenous and endogenous plants. Vari s objections, however, have been urged against it by Deca lolle and others, and farther observations are still requ ed to confirm it.

ecandolle does not deny that buds, or the leaves which they pr uce, have some influence in the formation of wood, but th action, he says, is entirely physiological, and depends on eir elaborating the descending sap by which the young wo d is nourished. While Du Petit Thouars attributes to th buds the origin of woody fibres, and to alburnum and lib their nutrition, Decandolle thinks that leaves produ the nourishment, and that the fibres are developed by th iber and alburnum. These opinions embrace the chief po ts under dispute, and further elucidation of them is re ired before we can come to a decided conclusion relative to e origin of wood. Physiologists seem at all events no to be agreed on this, that the formation of wood depe s, in some measure, on the action of leaves freely expo d to the sun or bright light. We have before remarked th when the parts of plants have been once formed, they co inue permanent, unless removed by accident or disease; th vegetables possess no power of removing decayed orga by *internal* absorption, as occurs in the animal syste but that their powers of regeneration are confined to th eproduction of parts or organs which have been removed by ecay, by accident, or disease.

ART. V.—*Of the Changes which the Sap undergoes in the Leaves from the agency of Light.*

In what has hitherto been said, we have supposed the functions of nutrition and growth in plants to be carried on, as in seeds, by the combined agency of water, heat, and air, without the access of light. Light is injurious to the growth of seeds, by impeding the change of *fecula* into sugar, which is so favourable to germination; and that it also retards the formation of saccharine matter in plants, is proved by many facts familiar to every one in the cultivation of celery and other plants, which, when secluded from light, not only lose their colour, but acquire a mild, and even sweetish taste. If a plant, says M. Achard, be covered with a glass vessel, it is observed sometimes to change from a sweet to a bitter taste; but if the vessel be opaque, the same plant, in its subsequent growth, will retain its sweetness. In the year 1774, the late Professor Robison observed, that tansy, mint, and other plants, which had grown in a dark coal mine, although they throve well in darkness, lost their colour, their odour, and their taste. But when they were brought up and set to grow in day-light, their white parts died down, and the stocks then produced the proper plants in their usual dress, and having all their distinguishing properties. When deprived of light, says Dr. Irvine, all plants nearly agree in the qualities of their juices. The most pungent vegetables then grow insipid; the highest flavoured, inodorous; and those of the most variegated colours are of a uniform whiteness. Vegetables which grow in a natural situation, he adds, readily burn when dry; but a vegetable, bred in a dark box, contains nothing inflammable. The results of analysis perfectly accord with these observations; for etiolated plants are found to yield more saccharine matter, carbonic acid and water, and less inflammable matter than those which are green.

From the facts above stated, it appears, that, when deprived of light, plants continue to grow; that the juices which support this growth are then nearly alike in all; and that they acquire their peculiar properties as to colour, odour, taste, and inflammability, only when vegetation proceeds under the direct influence of light. To the agency of the air, therefore, we may ascribe those changes in the vegetable juices, which render them fit for nutrition and growth; while light bestows on them those more obvious and active qualities, on which their colour, odour, savour, and combustibility more immediately depend. The first series of effects resembles those which were exhibited in the germination of seeds, from which process light is excluded; the second series is superadded to the former, and is directly attributable to light. It is on the leaves and succulent stems of plants that light chiefly acts; and it is in those parts that the proper juices, which give colour and peculiar character to plants, more especially reside. Are we then able to trace out the mode in which it produces any of these singular effects?

In all periods of active vegetation, plants uniformly convert the oxygen gas of the atmosphere into an equal bulk of carbonic acid gas; and if, at the same time, they grow in obscurity, they soon lose their green colour and become white. On the other hand, if they be made to grow in impure air under exposure to sunshine, they not only resume their green colour, but occasion a production of oxygen gas. This curious discovery was first made by Priestley. It has since been extended and confirmed by the experiments of Ingenhousz, Senebier, Woodhouse, and Davy; and more lately the subject has been treated with still greater precision by De Saussure. From the united labour of these writers we learn, that air, which has been depraved by animal respiration or combustion, is again, in certain circumstances, rendered pure by the aid of plants; that the air, which experiences this purification, must contain a portion of carbonic acid, either in an elastic form, or held in solution by water, and that it must be exposed, with the plant confined in it, to the influence of the solar rays; that neither the plant alone, nor light alone, will effect the decomposition of carbonic acid gas, which is accomplished only by their united agency; that only the leaves and other *green* parts of plants are able, by this decomposition of carbonic acid, to produce oxygen gas; and that the bulk of oxygen produced in these circumstances is exactly *equal* to that of carbonic gas which has disappeared. Hence, if plants be made to vegetate in a given bulk of atmospheric air, and placed alternately in obscurity and sunshine, carbonic acid is successively formed and decomposed; so that, as De Saussure ascertained, the air suffers no permanent change either in its bulk or composition.

This operation of plants in purifying air was deemed by Priestley a *vegetative* function carried on by the aid of light; and by Ingenhousz it was ascribed not to vegetation, but to the influence of light combined with a certain state of vegetable structure. As plants grow in obscurity, where they produce no oxygen gas, this operation cannot be deemed essential to vegetation; and, on the other hand, the decomposition of carbonic acid is effected by the combined agency of plants and solar light, in situations and under circumstances where vegetation cannot exist. Thus, if plants be placed in sunshine, they produce oxygen gas either when immersed in vessels of water saturated with carbonic acid, or when confined in pure carbonic gas. So likewise a similar decomposition of this gas is accomplished by plants, with the aid of light, in temperatures many degrees below freezing, and in such a state of mutilation as is incompatible with the proper exercise of their vegetative powers. Hence, in these different instances, the decomposition of carbonic acid is effected by plants without the aid of that oxygen gas, or that degree of heat, or that condition of structure, which are essential to vegetation; while, on the contrary, it occurs only under exposure to light, which, as we have seen, is not necessary to vegetable nutrition and growth.

But the operation of light, which is thus necessary to the decomposition of carbonic acid, is required also to produce the *green colour* in plants; and exclusion of light, which prevents this decomposition, prevents also the appearance of that colour. The two effects, indeed, are not only accomplished by the same agents, acting in the same circumstances, but, as far as observation extends, are simultaneously performed; whence it may be inferred, that some necessary connection subsists between them; and, could we discover this, it might lead us to an explanation of the green colour of plants.

Senebier observed, with great care, the operation of light in rendering white leaves green. At first, in different places are seen yellow spots, which gradually become deeper, and at length green. These spots multiply, extend, and meet on the face of the leaf, till at last it is rendered entirely green. If part of a white leaf be secluded from light, by covering it with tinfoil, that portion continues white, while the other parts become green; or, if a green portion be similarly covered, so as to exclude the light, it gradually loses its green colour, while the neighbouring parts retain it. From these and similar facts, Senebier considered the green colour in plants to be effected by the direct agency of light, independently of vegetation. He remarked, that a singular relation subsists between the parts of green leaves that furnish most oxygen, and those parts of white leaves which first become green; and from the circumstance of carbonic acid being decomposed and its oxygen expelled only when these parts became green, he was led to ascribe the green colour to the retention of the carbon of the decomposed gas, and its deposition in the cellular tissue of the leaf.

Mr. Ellis considers that the deposition of carbon in the manner above stated is not sufficient to change the colourless juice of the leaf to a green hue, and supposes that these colours are owing to the predominance of acid or alkaline matter. In support of this theory, he states that alkaline matter is an abundant ingredient in leaves; and the observations of Hales, Du Hamel, Coulomb, Knight, and others, show that carbonic acid is largely carried in with the sap, either in solution or in combination with alkaline matter. With the alkali already present in the leaf, the excess of acid in the sap will readily combine; and according to the proportion in which acid and alkali are present, the leaf will be variously coloured. If the acid abound, as in etiolated leaves, the leaf will be white; but if means can be found to withdraw this acid, and render the alkali predominant, then the green colour will appear. "Now, the decomposition of carbonic acid in plants, by the agency of solar light, seems to be the mean employed by nature to accomplish this purpose; for by this mean," says Mr. Ellis, "the acid is not only withdrawn from its combination, and its oxygen expelled, but the alkali at the same instant becomes predominant, and exists, therefore, in a state fitted to exert its specific action on the colourless juices of the plant, which, in consequence, are rendered green. The coloration of the leaf, therefore, is not owing immediately to the decomposition of carbonic acid and expulsion of oxygen, but to the predominance of alkali which that decomposition occasions. Hence, in the earlier stages of the process, we cannot so properly say that the green leaf affords oxygen, as that it becomes green when that gas is expelled; and thus it is that the decomposition of carbonic acid in leaves, by the agency of solar light, gives rise at once to the production of oxygen gas, and the formation of the green colour in plants."

But though light thus appears to be the active cause of colour in plants, yet, as it acts only by rendering alkali predominant in their juices, it follows, that if, from the soil, or in any other manner, a similar predominance of alkali arise, these juices will be rendered green. Hence certain buds and the germs of some seeds, and parts which lie within the bark of certain herbs, exhibit a greenish hue, though perfectly secluded from light; so that it is not to be doubted, as Senebier remarks, that plants, and parts of plants, may become green, although light should not act immediately upon them.

If thus the predominance of alkali occasion a green colour, then deficiency of it, and, still more, excess of acid, should have a contrary effect. Accordingly, when light is excluded from plants, no carbonic acid is decomposed in the leaf, and then its retention and accumulation, by saturating the alkali, subdue the green colour, and give rise to the white appearance observed in etiolated plants. So, likewise, the changes of colour which leaves exhibit in autumn seem to arise from the abundance of acid matter, not, however, occasioned by the absence of light, but developed under the various conditions of decay and decomposition in which they are then placed.

From the facts stated above, with regard to the alternate consumption and production of oxygen gas by growing plants, a question has arisen, whether, on the whole, vegetables purify or deteriorate the atmosphere. We cannot enter further into this question than to observe, that it is not to be decided altogether by experiments made in close vessels of artificial mixtures of air, but demands a comprehensive survey of vegetation in different climes, and a knowledge of the times and circumstances in which the one or other process prevails, or is variously accelerated or retarded. Since the production of oxygen arises solely from the decomposition of carbonic acid in the plant, we must also know the modes and quantities in which that gas is supplied to plants; for the power of plants to produce a large excess of oxygen, when confined in artificial atmospheres that contain from 7 to 10 per cent. of carbonic acid, does not at all apply to the natural condition of the atmosphere, which contains less than a thousandth part of that gas. We have already remarked, that carbonic acid is largely carried into plants with the rising sap; and various facts seem also to prove, that, when plants are confined in close vessels containing carbonic acid, that gas enters the leaf in an elastic form. Other gases, as oxygen, hydrogen, and azote, under similar circumstances, also obtain admission; and fleshy leaves, in particular, take up, through the night, a volume of oxygen greater in bulk than themselves, which, according to De Saussure, they again give out when exposed to a bright sunshine. It is not yet determined in what way elastic fluids thus obtain admission into leaves, and are again expelled from them; but the indiscriminate mode of their entrance and expulsion, at times, too, and under circumstances, in which vegetation is completely suspended; their long retention in a bulk greater than the containing body, and other circumstances, which we have not room to detail, lead to the belief that the phenomena are quite distinct from those which properly constitute vegetation, and are attributable to the conjoined operation of mechanical and chemical causes, aided by a certain condition of structure in the vegetable organs.

When, in the experiments of M. de Saussure, plants were made to vegetate in atmospheric air, and placed alternately in sunshine and in darkness, the decomposition of carbonic acid in the former case so exactly balanced its previous formation in the latter, that the air suffered no permanent change either in purity or in volume. Even in sunshine, as the same author remarks, plants growing in close vessels continue to produce carbonic acid, and it is only because they then also decompose it, that they do not permanently vitiate the air: hence, if a substance that attracts the carbonic acid as fast as it is formed be placed in the vessel, the air of the vessel no longer preserves its volume, nor its proportion of oxygen gas.

Professor Burnett recently made some experiments on the changes which growing plants produce on the air, and came to the conclusion, that the production of oxygen and its converse, the formation of carbonic acid, are the unvarying results of two different functions; the former being the product of *digestion*, the latter of *respiration*, and both being vegetative functions dependent on vitality. The formation of carbonic acid, he states, is constant by day and by night during the life of the vegetable; it is equally carried on whether the plant is healthy or unhealthy; it is essential to its existence, and for the sustentation of its irritability; for, if deprived of oxygen, and confined in carbonic acid gas, plants, like animals, quickly die. This function, which is performed chiefly by the leaves and petals, though also in a less degree by the stems and roots, is, like the respiration of animals, attended with and marked by the conversion of oxygen into carbonic acid, and is in fact the *respiration* of plants.

Again, vegetables at certain times, and under certain circumstances, decompose carbonic acid, and renovate the atmosphere, by the restoration of its oxygen. This restoration, however, is dependent not on the respiratory, but on the digestive system. It in part arises from the decomposition of water, but chiefly from the decomposition of carbonic acid, absorbed either in the form of gas or in combination with water. And here again there is a marked analogy between the functions of respiration and digestion in plants and animals; for to both is carbonic acid deleterious when breathed, and in both it is invigorating to the digestive system when absorbed as food.

The presence or absence of light appears to have little or no influence on vegetable respiration; but it produces very notable effects in the assimilating powers of vegetables, by enabling them to separate from the air and water those principles which are necessary for their support, and to liberate such others as may be too abundant in the crude aliment which they absorb. Thus digestion or assimilation tends to increase, respiration to decrease the solid materials of plants.

Mr. Ellis, who has written most ably on the influence which plants exert on the air, agrees with Burnett in thinking that the function of nutrition is entirely distinct from that of respiration; the former process being primarily carried on by the roots, and the matters ultimately rendered fit for assimilation in the leaves. The leaves themselves, he says, apparently exert two opposite actions in the different circumstances of shade and sunshine, or night and day. In the shade and through the night they convert oxygen gas into carbonic acid gas, which is easily detected, because little or no purification of the air is then carried on. Even in sunshine, as De Saussure has shown, plants exert the same power in deteriorating the air; but it is not then so readily discoverable, because the acid gas which is formed is at once decomposed by the direct agency of solar light, and the purity of the air is restored. The former process, by which oxygen gas is converted into carbonic acid gas, he regards as the true respiratory process, essential to nutrition and growth; the latter, as a chemical operation effected by the agency of light, and contributing immediately to the colour, odour, and certain other sensible properties of the plant.

Professor Liebig, who has recently made some observations on this subject, maintains that plants derive their carbon exclusively from the decomposition of carbonic acid, chiefly, or often entirely, supplied by the atmosphere; that they at the same time restore oxygen to the atmosphere; that the decomposition of carbonic acid is arrested by the absence of the light, and then plants appear to produce and evolve carbonic acid; that at night a true chemical process commences in consequence of the action of the oxygen in the air upon the organic substances composing the leaves, blossoms, and fruit; that this is not connected with the life of the vegetable, but is in fact a process of oxidation. He also states, that the humus or fertile ingredient of the soil nourishes plants only by being a lasting source of carbonic acid, which it emits very slowly. The hydrogen which enters into the constitution of plants he thinks is derived from water, and the nitrogen from the decomposition of the ammoniacal salts contained in the soil.

Recent experiments have proved, that the quantity of carbon fixed by a plant exceeds that given off by the process of respiration; and Dr. Daubeny has shown, that if a plant with leaves and stem be confined in the same portion of air, day and night, and duly supplied with carbonic acid during sunshine, it will go on adding to the proportion of oxygen present, so long as it continues healthy; the slight diminution of oxygen and increase of carbonic acid during the night, bearing no considerable ratio to the degree in which the opposite effect occurs during the day. Plants, then, must be regarded as the chief provision employed by nature to maintain the purity of the atmosphere of our globe.

Beside contributing to their *colour*, light, as we have seen, exerts a direct action on the substances which impart odour, taste, and combustibility to vegetables. These several qualities depend immediately on the oils, volatile and fixed, the resins, gum-resins, balsams, and turpentines, the alkalis and acids, the earthy and saline compounds, and the tannin, extractive, and other principles met with in the proper juices. It is probable that these substances are formed in the leaves and other corresponding structures, chiefly by peculiar secreting organs; but either the functions of the organs, or the products which they yield, appear to experience great modifications and changes from the direct action of light; and hence, if this agent be wholly excluded, these vegetable products are either sparingly formed, or not at all produced. When formed, they become mixed with the sap in its course through the leaves, and variously change its sensible properties, so as to constitute juices proper to each species of plant. Thus blended with the sap, they are conveyed, more or less abundantly, through the organized parts, and impart to them those properties of colour, odour, taste, &c. observed in the several textures. Sometimes the gummy and resinous matters exude on the surface of the tree, or stagnate in the vessels or cells of the bark and wood, forming those collections and concretions to be found in different parts of those textures. All these ingredients of the proper juice serve, in vegetation, purposes different from those of the mucilage, starch, and sugar, from which the secretion called *cambium* is derived, and which is more immediately employed in the production or nourishment of new vegetable matter.

In these operations of light on plants, it is probable that the several species of rays that compose the solar beam exert specific but varied actions. The violet rays, or rather the invisible rays associated with them, were observed by Senebier to act most powerfully in producing the green colour of plants; and he likewise ascertained that they act by their own peculiar quality, and not by their heating or illuminating power. This agrees with the acknowledged power of this portion of the solar beam in producing decomposition, since it is through the decomposition of carbonic acid in plants that their green colour is obtained. The experiments of De Saussure also shew, that by this decomposition of that acid gas, not only is oxygen gas expelled from the plant, but the proportion of its carbon increased; but whether this carbon contributes to the formation of any of the more active ingredients of the proper juices, or of those which impart colour, or whether the calorific power of the solar beam acts in their production, nothing yet known enables us to determine.

CHAP. II.—OF THE FUNCTIONS OF THE INDIVIDUAL MEMBERS AND ORGANS OF VEGETABLES.

SECT. I.—*Of Buds, and of the Members and Organs produced from them.*

ART. I.—*Of Buds.*

Having thus exhibited a brief outline of the leading facts which constitute vegetation, as exemplified in the nutrition and growth of plants, we have now to notice, in a manner still more brief, the functions of certain parts and organs which serve different uses, and afford various products; and more especially those by which the continuance of their race is maintained. Some plants pass rapidly through the several stages of their existence, and having produced their seeds, fade and die; others continue for one or more years; and many prolong their existence to very distant periods. Even in these latter, the more active organs of vegetation, after producing their fruits and seeds, fade and fall like plants of shorter duration; and when the season adapted to the growth of *annuals* returns, then also *perennials* reproduce all the organs necessary to growth and fructification. In ordinary cases, reproduction in annuals is continued only by seeds; in perennials, both by seeds and buds. For an account of the species of buds, and of their formation and structure, we must refer to our former article: at present we can only afford space for a few observations on those varieties of buds which produce branches, leaves, and flowers.

During summer and autumn, when perennial plants add to their bulk by the formation of new layers, they also form new buds on the sides and at the extremities of their branches. These buds continue to enlarge through the autumn, and in part through the winter; so as to be ready, on the return of spring, to shoot forth, and supply the place of those that annually decay. Some buds chiefly produce wood, others leaves, others flowers, and others both leaves and flowers; and this variety of production may be so modified by culture as to enable us often to substitute one species of bud for another. The wood and leaf buds are the result of vigorous growth, and are primarily of the same structure. As the plant approaches to maturity, or when the vigour of its growth abates, then flower-buds augment in number.

Buds naturally remain attached to the parent tree, and there execute their allotted functions; but they may also be made to grow as individuals, or be transferred, in various modes, to another stock, and perform the same functions on it, as on their proper parent. Though supplied then with sap from a different tree, they retain the power of effecting in that fluid the same changes, and forming with it the same products as they would have produced on their native stock. The bud of the tree, therefore, like the embryo of the seed, must be held to possess individuality of character, and to be capable of producing new individuals perfectly similar to itself. To the embryo of the seed, however, as to every organised body, is assigned certain periods of infancy, maturity, and decay, which may be varied in duration from accidental causes, but can never, beyond certain limits, be changed. What is true of the primary embryo of the seed, is true also of all the buds propagated from it, whether they remain on the parent stock, or are transferred to another. Hence, when the period arrives in which the function of reproduction naturally ceases in the buds of the parent tree, all the buds, growing on foreign stocks, indicate the same character of age, and cease to bear fruit; and for the permanent continuance of the species recourse must then be had to a seminal progeny. Mr. Knight has very ingeniously applied these principles to account for that failure in bearing fruit which the oldest and best varieties of trees in the cyder districts exhibit. Although grafts from these trees still grow on foreign stocks, yet they do not now yield fruit as formerly, because the trees, from which they have been taken, have outlived the fruit bearing period.

ART. II.—*Functions of Branches, Thorns, and Tendrils.*

In its progressive growth, the bud, under its various forms, gives origin to branches, with their various appendages of thorns and tendrils, of leaves and flowers. The functions of the branch may be considered as similar to those of the trunk; which indeed it so nearly resembles in structure and growth, that, if cut off and planted, it readily, in many species, puts forth rootlets and buds, and becomes a perfect tree.

The thorns of trees may be regarded generally as abortive branches, which assume their form chiefly from defective nutrition; and hence, as Malpighi observed, they often disappear under higher culture. Sometimes, however, they derive their origin from the degeneration of other organs, as from the stalks of leaves and flowers. They serve as a defence to plants, and protect them from the ravages of animals.

The several varieties of *fulcra* called claspers and tendrils have the same structure as branches; and, like thorns, sometimes originate from abortive leaves and flowers. Their obvious use is to connect the different parts of a plant with one another for mutual support, or to attach themselves, for the same purpose, to the bodies near them. Sometimes this purpose is assisted by means of a viscous secretion which they yield, and which glues them to neighbouring bodies with much force.

ART. III.—*Functions of Leaves.*

The leaves spring from the buds chiefly of young br ches, and by their number, forms, and colour, constitu the chief ornament of trees. If they exhibit less sp ndour than flowers, they enjoy a longer existence. They fu ish to animals a large part of their subsistence, afford th n shade and shelter, and spread everywhere beneath ar around us, that "all-refreshing green," on which the ey fatigued and distracted by the glare of other colours, al ays loves to repose.

We have already discoursed largely of the functions of th leaves as organs of respiration and of transpiration. B ides this transpiring power, the leaves exercise also an ab rbent function. From the experiments of Bonnet it ppears, that the leaves of many herbs, when laid upon w er, absorb equally well by both surfaces, but those of tr s only by the under surface: and these facts correspond w h the observations of Decandolle and Rudolphi, as to th existence of stomata on these surfaces respectively. T e power of the leaves to absorb moisture from the air w also abundantly proved in many of the experiments of H es and Du Hamel, and more recently by those of K ight. This absorption appears to be carried on by the m ute vascular terminations which open at the pores; and is pparently performed by the same vessels, which, at a d erent time, and under different circumstances of temp ature and humidity, execute the function of exhalation.

Beside the aqueous fluids given off by leaves, others are so etimes afforded, which seem to be secreted by peculiar or ans. On the leaves of different plants, mucilaginous, sa charine, resinous, or oily fluids are sometimes seen; or if nvisible by the eye, they are often sensible to taste and sm ll. In some leaves, these secretions appear to proceed fr m minute glandular organs, seated in the cellular tissue; in thers, small follicles in the cuticular texture seem to fu ish them. Of the structure of these minute organs li e is known, and still less of the mode in which they e cute their functions. Of the influence of light on the se reted fluids of the leaf we have already spoken; and also o he mode in which it contributes to the production of its g en colour. Bonnet has likewise shown that light ex- e a great power over the motion or direction of leaves, o which some notice will be hereafter taken.

ART. IV.—*Functions of Roots.*

So nearly does the root agree in structure with the trunk, th t, as Malpighi observes, we may consider it as a producti of the trunk beneath the soil. From the principal r t or stock proceed the buds that give origin to the prim y rootlets; and these give off finer ramifications, at the e remities of which are formed the spongioles or spong ets, which are the true absorbents of the root. These fi absorbents take up the nutrient matter from the e th, and convey it to the root, from whence it is sent to t trunk. Where these absorbents extend, the earth is e austed of its nutrient matter, and not in the neighb urhood of the larger roots. In a severe winter, Du H mel found these fine rootlets to die, and to be abund ntly replaced by others, when the temperature became r der. Not only the root, but the branch of a tree, r dily produces rootlets, if it be amputated, and set to g w in water or in soil. The form of the root is much i uenced by the texture of the soil. If the soil be easily p etrable, the root descends in the form of a long tapr t; but if it be hard and resisting, then the root r ins shorter, and divides into lateral branches. Du Ham l remarks that roots extend into that portion of soil w ich is richest, while the barren parts are nearly destitute o them; so that the qualities of the soil, as well as its text e, exert the greatest influence on their direction and growth. In regard, however, both to composition and texture, different soils are best suited to different kinds of roots. We have before remarked, that the elongation of roots and rootlets is made by the addition of new matter to their extremities, not, as in succulent branches, by the simple extension of parts already formed. The diametral growth of roots is effected, like that of the trunk, by the formation of new layers between the bark and wood.

ART. V.—*Functions of Flowers.*

Flowers may be regarded not only as the last, but the most elaborated organs of the vegetable system. Whether we contemplate the beauty of their forms, the splendour of their colours, or the delicious fragrance which they breathe around us; or whether, with a physiological eye, we survey the delicacy of their structure, and investigate the peculiar functions which they perform, we cannot but feel the greatest admiration of the skill with which, in a compass so small, and by means apparently so simple, such a series of actions, terminating in results so varied and important, can at once be combined and regulated.

The flower is attached to the plant that bears it by the peduncle, on the extremity of which is placed the cup or calyx, which, in its turn, supports the corolla, and the organs of reproduction. Of these organs, the male parts consist of one or more stamens, formed by the filament, bearing on its top the anther, which contains the fecundating particles, named pollen. The female organs consist of one or more pistils, the style of which bears on its top the stigma, and terminates below in the ovary that contains the rudiments of the seeds. For an account of the structure of these several parts, we refer to our former article.

Various as are the forms, colours, and functions of the several parts of the flower, yet, in structure, they are so similar, that, under a change of circumstances, almost any one part or organ can be made to assume the character of any other. Thus, not only are the petals of the corolla, or the stamens and pistils, sometimes abortive, but, at other times, the stamens become simple filaments or petals, or the petals take the form of stamens. Sometimes, again, the style of the pistil changes into a petal: in other instances, the petal becomes a floral leaf, or the calyx is changed into real leaves. In like manner, as leaves, or their petioles, are sometimes transformed into claspers and tendrils, so the peduncles and petals of the flower now and then exhibit similar transformations. Nor are these transformations confined to leaves and flowers; they extend to the more solid and permament members of the plant. Thorns, we before remarked, were but abortive branches; and as a branch, by surrounding it with earth, may be made to throw out rootlets instead of buds, so a root, when brought into light and air, will, on the contrary, put forth buds. Even an entire tree may be inverted, and the roots and branches, by being placed in circumstances respectively opposite to their nature, may be made gradually to assume each other's character, and execute each other's functions. These facts demonstrate a great uniformity of structure in all parts of vegetables, and show with what facility modifications of form and of function are induced, by varying the application of those external agents and conditions, concerned in the development of vegetable organization.

1. *Colours of Flowers.*—The *colours* of flowers are not less diversified than their forms. They present every variety of tint and every shade of intermixture; and not unfrequently the same flower, at different times, or even at the same time, exhibits great diversity of colour. Grew remarked that no flower has its proper colour in the bud; that many of them are then pale or white; and that the full and proper colour is formed only when they expand. Even after their expansion, the colour of some flowers, as that of the rose, may be made to disappear by secluding it

from light, as Sir Humphry Davy remarked; and the flower of honeysuckle, which continues white while the light is excluded, acquires its red hue on exposure to light and air. It has not however as yet been ascertained what influence air and light exert on the colour of flowers. Ellis believes that, as in the case of leaves, the predominance of air and alkali may be the cause of the different colours of the petals. It is, however, probable that the chemical condition of the juices themselves, or the textures by or through which their colours are reflected or transmitted, are modified by variations of structure in the organs, which altogether escape detection, and become known only in their effects. Du Hamel considered many varieties of colour in the flower to arise from the intermixture of different species and varieties of plants, at the period of fecundation. Poppies and primroses, which grow wild in our fields, are respectively red and yellow; but the same plants, transferred to our gardens, furnish a prodigious number of varieties. If the wild variety of primrose be removed from its natural place, and set to grow among cultivated varieties of the same kind which possess different colours, the seeds obtained will produce many yellow flowers, because the parent plant will have been fecundated by some of its own stamens; but it will also afford other varieties, because some of the seeds will have been produced by fecundation of neighbouring plants. Many of the fine varieties of flowers which florists procure by means of seeds, seem to be thus obtained. They indeed attribute them to some particular infusion with which they have watered their seeds, or to some colouring matter which they have mixed with their soil, or even to some differently coloured bodies which they have presented to their plants, or to a singular good fortune peculiar to themselves. "I have tried without success," says Du Hamel, "these infusions and these mixtures of colours; and I deem it unnecessary to resort to experiment to destroy the other two means." In the ultimate production of colour, modifications may also proceed not only from the texture of the parts, but the configuration of their external surface, as exemplified in the prismatic tints of "mother-of-pearl," which, according to the observations of Sir David Brewster, owe their existence to the configuration of the surface alone. Schubler and Funk, in a memoir published at Tübingen in 1825, have made some interesting observations on the colour of plants. They have divided flowers, in reference to their colours, into two series: 1st, the Xanthic series, or those having yellow for their type, or which are capable of passing into red or white, but never into blue; 2d, the Cyanic series, or those having blue for their type, and capable of passing into red and white, but never into yellow. For an account of these observations, as well as those of Köhler, on the colours prevalent in different natural orders, &c. we must refer the reader to the memoirs themselves, as it is impossible, in the space allotted to us, to give any thing like a correct view of the subject. From numerous experiments made on various leaves and flowers, Dr. Hope was led to the conclusion, that *chronogen*, or the colourable principle, is not an individual substance, as hitherto supposed, but that there are two distinct principles, one which forms a red compound with acids, which he names *erythrogen*, and another, which affords a yellow compound with alkalies, which he calls *xanthogen*. These principles exist sometimes separately, and sometimes together in different plants, or in different parts of the same plant. All green leaves, all white, and all yellow flowers, and white fruits, contain xanthogen alone; while in red and blue flowers, and in the leaves of a few plants which exhibit the former of these tints, the two principles occur together. Light, says Dr. Hope, is indispensable for the production of the green chromule of leaves, but not for the formation of some of the finest tints of flowers and fruits, if essential for any; differences probably connected with the fact, that the formation of the green colour in leaves is always accompanied, or rather preceded, by the evolution of oxygen gas.

2. *Odour of Flowers.*—Next to colour, the property in flowers that most strikes our senses is their odour. Other parts of plants, indeed, possess odour; but the finer and more diffusible fragrance that emanates from them proceeds commonly from the flower. Of the peculiar organs in flowers which form and emit odorous particles, but little is known. Their ordinary seat is probably in the *corolla*, since many flowers, which are wholly destitute of sexual organs, emit their peculiar odours. Of the nature of the odorous matter, all we at present know is, that it is inflammable; and this property, M. de Saussure considers to depend rather on the presence of an essential oil, than on any variety of hydrogen gas. That light is more especially concerned in its production seems probable from the fact, already stated, that the most pungent odours cease to be formed in plants which are kept secluded from light; but are speedily produced in them when restored to its presence. In climates and situations where the sun exerts the greatest influence, plants possess the most exalted odours and the most active inflammable ingredients; but of the mode in which the solar rays act in thus contributing to produce odour and inflammability in plants, little is at present known. Schubler and Köhler have also made observations on the odour of plants, as connected with colour; for which we must refer to the memoirs already mentioned.

3. *Savour of Flowers.*—Connected with the odour of plants, at least in the mode of its production, is the property which they possess of imparting sensations of taste. This property is more generally distributed through the vegetable, and is of a much less fleeting and diffusive nature than that of odour. Tastes have been regarded either as simple or compound; and of each a great diversity is to be found in plants. Tastes differ also in quality, degree, and duration; are more or less fixed or diffusible; and, in some instances, affect variously the different parts of the organ which receives the impression. Of all these, and some other varieties, Grew has given examples, taken from the savours of the juices found in the wood, bark, and root, or in the leaves, flowers, and fruits of various plants.

In general, however, the roots, and all those parts that are secluded from light, have a taste milder and less intense than others; and, as we before remarked, plants, possessing naturally a hot or bitter taste, become mild, or even sweet, by the exclusion of light, and resume their pungent and acrid qualities if brought into day. Light, therefore, exerts a direct action in the formation of the savours as well as of the odours and colours of plants. The odour and savour are commonly more concentrated in some parts than in others; and when formed in the leaves, they are frequently mixed with the proper juices, and more or less pervade every part of the plant. Although, therefore, the action of light, in the production of colour, odour, and savour, be, in the first instance, *local*, or confined to those plants, and parts of plants, exposed directly to its influence, yet these properties may afterwards be diffused, by the motions of the fluids, through all parts of the vegetable, including even those buried beneath the soil, and thereby protected from the action of light. From the whole it appears probable, that all the effects, simultaneously produced in plants by the direct agency of light, are in position local, in operation chemical, and in nature entirely distinct from that series of actions accomplished by the air, and which contribute to their evolution, nutrition, and growth.

4. *Fecundation of Flowers.*—Although in appearance the flower differs so much from the leaf, yet in structure it is very similar; and, for the due performance of its proper functions, not only requires the presence of the same

ag nts, but acts in the same manner upon them. The n essity of air to the growth of plants, and the conversion o its pure part into carbonic acid by the leaves, in every st e of that growth, have already been noticed; and P estley, Scheele, and Ingenhousz, showed that flowers, in ike manner, require air, and convert its oxygen into c bonic acid. De Saussure has since ascertained that fl ers do not develope in atmospheres destitute of oxygen g ; that, in proportion to their bulk, they consume more ox gen than leaves; and that the oxygen which disappears is eplaced by an equal volume of carbonic acid gas; so th little or no variation of bulk occurs in the air employed. U ike leaves, however, flowers do not produce oxygen gas in unshine. Under such an increase of temperature, they co sume even more oxygen than before; but no trace of th production, either of hydrogen or azote, is discoverable in he atmosphere in which flowers have been made to gr w.

onnected immediately with the great consumption of ox gen by flowers, is the high temperature which some of th n manifest at the period of fecundation. Lamarck an Senebier observed the flower of *Arum cordifolium* to in art the sensation of heat to the touch; and to possess, a tle after midday, a temperature 12° higher than that of th surrounding atmosphere. In the Isle of Madagascar, M lubert found that the same plant raised the thermometer st higher; that the male parts of the flower possessed, in th respect, greater power than the female, so that twelve st nens, placed round the bulb of a thermometer, raised it t the moment of bursting, from 70° to 121°; that this po er resided in the exterior surface, not within the subst ice of the organs; and, lastly, that air was necessary to th elevation of temperature, and was rapidly depraved in th process. In confirmation of these facts, De Saussure h since found that double or imperfect flowers consume le oxygen than those which are simple and perfect; that th greatest portion of this gas is consumed at the period of fe ndation; and that the stamens, adhering by their base to he receptacle, consumed more than other parts. He fu her ascertained that the temperature of many flowers ri s in proportion to the quantity of oxygen consumed; a , to the rapid combination of oxygen gas with the carb of the flower, he ascribes, with Senebier, the great ri of temperature which occurs, in certain flowers, at the p iod of fecundation.

his necessity of air to the development of flowers, ta en in connection with the chemical changes which it suffe , and the high temperature thence arising at the period of fe ndation, points to some peculiar action which it exerts in he exercise of the generative function. Not long after th true nature and use of the sexual organs had been m le known by Grew, Dr. Blair, in a learned essay on the *G eration of Plants*, maintained, that, while the greater p of the ascending sap passed on to the leaf, a portion w also carried to the petals of the flower, and, in its co rse through them, underwent that change and elaborati which fitted it for forming the pollen, and rendering th matter the proper means of fecundation. A similar op nion of the use of the corolla was held by Du Hamel. T petals, says he, are organs necessary to fructification. T y not only protect the stamens and pistils, but perfo n the office of leaves, in acting on the fluids of the sexual o ns, and perhaps effect in them some important preparat n. Dr. Darwin likewise considered the petals to act, by th agency of the air, in elaborating the juices destined to n rish and develope the sexual organs. These opinions assi to the less important parts of the flower functions esse ial to the perfection of the whole, and corresponding in nature with those executed by the leaves, only that " ture," as Grew observes, "hath lapped up the virtue in le es as in brown paper, but in the flowers as in leaf-gold."

When the organs of reproduction have attained their perfect state, and a suitable condition of the atmosphere prevails, the process of fecundation is accomplished by various modes in different plants. By the agency of the solar rays, aided probably by that high temperature which at this period they derive from the decomposition of the air, the anthers burst and discharge the pollen in the form of a fine dust. This dust, in some instances, falls directly on the stigma of the pistil previously prepared, by the secretion of a viscid matter on its surface, to receive and detain it. In other instances, the pollen is conveyed to the stigma by insects, or by the wind; and in others, its conveyance is accomplished in different modes. When the pollen has been shed, the stamens and petals soon begin to fade and fall; the filament of the pistil likewise fades; but the ovary at its base augments in size, and the pulpy globules, or vesicles, previously formed within it, enlarge, and gradually assume the form and character of the perfect fruit or seed.

The pollen, which occasions these extraordinary changes in the ovarian vesicles, is composed of small particles, enclosed in two coverings, and possessing a different colour, size, and figure, in different plants. These particles are organized, and, when observed in a bright sunshine with a microscope, may, in some plants, be seen to burst; and then a liquor like saliva escapes, in which, says Du Hamel, small particles are obscurely visible. Of the chemical nature of the pollen little further is known, than that it yields a peculiar matter, called *pollenin*, which is described as being of a yellow colour, without taste or smell, insoluble in water and alcohol, but highly inflammable, and yielding, by distillation, a good deal of ammonia, which approximates, in composition, to animal matter; but this knowledge gives us no insight into the nature of its peculiar action.

When the grains of pollen have lain for a short time on the stigma, they open at their angles, or in certain definite points of their surface, and emit long slender tubes called *pollen tubes*, which, according to Brongniart and Brown, are formed of the inner lining of the pollen grains. These pollen tubes, which are not above the 1500th or 2000th part of an inch in diameter, pierce the stigmatic tissue, and find their way down to the region of the placenta, conveying the matter contained in the grains into the interior of the style. The active molecules of the pollen are thus brought into communication with the foramen of the ovule, and are the means by which impregnation is effected. Although tubes enter the ovarium, and run along the placenta, it has not been proved that the true pollen tubes come in contact with the ovule. What is the nature of the communication made by the pollen to the ovule, through the medium of the pollen tubes, and the result of which is fertilization, we have no means of knowing. Some consider it a peculiar stimulus, which is required to call into existence an embryo germ of life, residing in the point of the nucleus; others say that it is the act of conveying such a germ to the nucleus from the pollen grains. The latter idea has been supported by Schleiden, whose ingenious views on the subject are published in the Nova Acta Academiæ Naturæ Curiosorum, &c., vol. xix.

On this subject, Brown remarks, that our knowledge appears not yet sufficient to warrant even conjectures as to the form of the immediate agent derived from the male organ, and the manner of its application to the ovule, in the production of that series of changes constituting fecundation; and he at the same time remarks, that in investigating the obscure subject of generation, additional light is perhaps more likely to be derived from a further minute and patient examination of the structure and action of the several organs in *asclepiadaceæ* and *orchideæ*, than from that of any other department either of the vegetable or animal kingdom.

But whether the pollen act directly or indirectly on the ovarian vesicle, there is little doubt but its influence is necessary to the perfection of the seed : for though, as Ray observed, some fruits may be produced without the concurrence of the male parts of the plant, just as some birds will produce eggs without the concurrence of the cock, yet such fruits, like such eggs, are altogether barren and unproductive.

To the impregnation of one species of flower by another of a kindred nature, through the agency of winds and insects, Du Hamel ascribed most of the varieties of fruits denominated new. In some fruits, the species, in the hybrid production, are kept so distinct, that we are able to distinguish one part from another, with which it had been associated at the period of fecundation. Thus, there is a species of orange, which, on the same tree, says he, produces "des bigarades, des citrons, et des balotins séparés, ou même rassemblés par quartiers dans le même fruit." In like manner, a certain species of vine produces, on the same shoot, bunches both of red and white varieties ; or on the same bunch both red and white grapes ; or bunches on which the grapes are red and white by halves, or even by quarters. These diversities in fruits he attributed to the impregnation of one species by the pollen of another ; and to a similar cause, as we before stated, he ascribed many of those diversities in the colours of flowers, where different varieties grow and blossom together. Others have made many direct experiments on the reproductive function in plants by *crossing* different species with each other ; and, by a judicious extension of the same methods, Mr. Knight has been able to present us with several new and improved varieties both of seeds and fruits.

ART. VI.—*Maturation of Fruits.*

The period that intervenes between fecundation and that in which the ripening of the fruit or seed is completed, varies in different plants, and even in the same plant, is much modified by climate, season, habit, &c. Whatever, to a certain extent, diminishes the vigour of vegetation, favours the production and accelerates the maturation of the fruit. So long as trees continue to shoot and abound in sap, says Du Hamel, their fruits do not arrive at maturity. By stripping them of their leaves, we hasten this period, not so much, however, by exposing the fruit to the sun, as by weakening the flow of the sap. But if the tree be stripped before the fruit has reached its proper size, both its size and quality are bad. As the powers of vegetation decline, the fruit advances towards maturity ; and then exposure to the sun, by promoting transpiration, and concentrating the juices of the fruit, hastens the ripening process. At an earlier period, however, the same degree of exposure, by exciting too great transpiration, might cause the fruit to languish and wither. When fruits are enclosed in bags to protect them from wasps, transpiration is checked, and the fruit enlarges; but has not so good a flavour as usual. The present taste for what are called "fine fruits," seems directed chiefly to size, and is content to resign the rich and racy flavour, found only in fruits of a moderate bulk, for the pampered and bloated produce of a too luxuriant vegetation.

Ingenhousz formerly maintained that fleshy fruits, whether ripe or unripe, and whether growing in sunshine or in shade, always vitiated the air in which they were confined : and in a late Memoir on the Maturation of Fruits, M. Berard has adopted the same opinion, and maintained that green fruits do not decompose carbonic acid and disengage oxygen gas in sunshine, but that, through every period of their growth, they uniformly convert the oxygen of the air into carbonic acid gas. To this Memoir, M. de Saussure, who had formerly combated the opinion of Ingenhousz, has replied by new experiments; and has satisfactorily proved, that although, during the night, green fruits convert the oxygen gas of the air into carbonic acid gas, yet that, when exposed to sunshine, they again reconvert this carbonic acid into oxygen gas ; so that, if they be placed alternately in sunshine and in obscurity, for two entire days, the air of the vessel undergoes successive changes which nearly counterbalance each other, and at the close of the experiment no other degree of change exists in it, than may be attributed to errors of observation. Hence it is inferred, that, both in the shade and in sunshine, green fruits act upon the air like green leaves; but this action is carried on to a smaller extent, and diminishes as they approach maturity.

As thus the air, under similar circumstances, suffers the same changes from green fruits as from leaves, it may be presumed that the fruit owes its green colour to the same action of light upon it. Light seems also to act in the production of the other colours which fruits exhibit. M. Bonnet shut up, in cases of white tin, grapes of a black colour, which did not then acquire their natural hue. Pears, says Du Hamel, which grow in the shade, are often green, while others, exposed to the sun, are beautifully coloured; and the same things are observed in peaches. Neither peaches, pears, nor cherries, assume their proper colours, if, at the period of ripening, says Senebier, they are secluded from light; and if a portion of fruit be covered with tin-foil, that part will continue pale or yellow, while the uncovered portions of the same fruit become perfectly red. If the red juices of fruits be extracted by water or alcohol, they are affected by acids and alkalis like those of flowers; and similar changes are produced by these agents on the coloured infusions obtained from their skins. These facts show that the same chemical actions, which occasion the colour of leaves and flowers, are employed in the coloration of fruits: but in these latter, they are probably much modified by the chemical changes that go on in the fruit itself during the process of maturation.

To discover the chemical changes that take place in the fruit during its maturation, M. Berard analyzed several fleshy fruits at different periods of their growth. With this view, three apricots of the same size were selected, and being plucked in succession, one of them was analyzed at three different stages of growth, namely, in its green state, in a state more advanced, and in a ripe state. The several results are given in the following table.

Apricot very Green.		Advanced.	Ripe.
Animal matter...	0,76	0,34	0,17
Green colouring matter..........	0,04	0,03	Yellow 0,10
Woody fibre.....	3,61	2,53	1,86
Gum	4,10	4,47	5,12
Sugar	traces of	6,64	16,48
Malic acid........	2,70	2,30	1,80
Lime..............	a very small portion in the three.		
Water.............	89,39	84,49	74,87

In the interval between the first and last analysis, the fruit had so much increased in size, as nearly to double its weight. It will be seen that, with the exception of the green colouring matter, which had become yellow, all the ingredients found in the unripe fruit were present in the ripe one, but some were in greater proportion. Sugar in particular had greatly increased, and water had diminished. From these results it is inferred, that the different flavours of green and ripe fruits are not owing so much to the disappearance of any primary ingredient, or its transformation into another substance, as to the production of new substances, and especially of sugar, made in the progressive stages of growth. Similar analyses of cherries, gooseberries, plums, and peaches, afforded the same results.

There are some fruits, however, as those of apples and pears, which ripen very well after they are detached from th ree ; and in these, sugar seems to be formed out of the oth r ingredients, as it is formed from fecula in the germina on of the seed. M. Berard plucked a pear from the tree wh n firm and green, and shut it up in a close vessel of atmo pheric air from the 12th to the 29th of August. Its co ur had then become yellow, and it was perfectly ripe. Du ng this period, its total weight had diminished very little and this was due to the loss of a little water, and a mi ute portion of carbon ; but the proportions of its ingredie s were much changed, for the quantity of sugar was ne y doubled, and that of gum, of water, and of woody fib had decreased. The united loss of the gum and woody fib was not, however, equal to more than half the gain of gar ; and therefore M. Berard supposes that water may ha become fixed, and augmented the proportion of this latt substance. If water be thus held to have contributed to e production of sugar in the pear, we may suppose it to ve served a similar purpose in the ripening of the apricot for the loss of water in the ripe apricot, as compared wit the green one, comes near to the gain of sugar ; and no ange in the relative proportions of the other ingredients car e deemed sufficient to account for the great increase of s ccharine matter.

he external agents required to effect these chemical cha ges in the maturating fruit appear to be heat and air. In e above experiment with the pear, the vessel was kept in temperature of about 82° Fahrenheit; and the air, as we as the fruit, underwent a change of composition. It ind d remained unchanged in volume ; but 100 parts of it elded, on analysis, 13·52 carbonic acid, 7·51 oxygen, an 78·97 azote ; so that, as in other cases, the loss of oxygen was supplied by an equal bulk of carbonic acid, since th nited volumes of the acid gas and oxygen made together alm st exactly the $\frac{21}{100}$ of oxygen gas which the air at first con ained. Hence no oxygen can have combined with the fru ; nor can the azote of the air be deemed to have undergo any necessary change, since the very minute portion of at gas unaccounted for may fairly be set down to error in periment. That this conversion of oxygen gas into car onic acid is necessary to the maturation of fruits, M. Be rd inferred from the fact that the process is arrested if fru be kept in an atmosphere destitute of oxygen; yet, aft being kept for some weeks in such an atmosphere, the pro ss recommences if oxygen be supplied.

this process of maturation, light, though ordinarily pre nt, and acting on the colours of fruits, does not seem nec sary ; for fruits will ripen in dark places ; and, to has n maturation, it is not uncommon to enclose bunches of pes in black bags, which must, at the same time, exclu light and accumulate heat. Whether light be actually unf ourable to the formation of sugar in fruits, as it appears to in seeds, remains to be ascertained ; but certainly, tho h it should retard, it does not prevent maturation : and its esence is ordinarily accompanied with such an increase of t perature as may more than compensate for its supposed inj ous operation. Since, also, the vegetating process gra ally diminishes as the fruit approaches maturity, and cea s to act upon it when its growth is completed, we cannot scribe the changes that constitute maturation to vegetati , but must regard it as a chemical change, effected by e reaction of the several ingredients of the fruit on each oth , under the operation of those external agents necessar o its occurrence.

Art. VII.—*Fecundity of Vegetables.*

e period required for the accomplishment of those cha es in the ovarian vesicles, which terminate in the for tion of perfect seeds, varies much in different species of nts, and also in the same species, under different circum ances of climate, soil, habit, &c. When they are completed, the ovary or pericarp, in which the seeds were contained, is opened, in various modes, for their discharge : or the fleshy pulp that invested them decays ; or the stony covering in which they were imprisoned is rent asunder ; so that, in one way or other, they are set free, and by various means are disseminated over the surface of the earth, destined either to reproduce new beings similar to themselves, or to minister to the gratification and sustenance of animal life.

Of the seeds thus produced, the number, size, figure, texture, and other properties, are infinitely diversified. With respect to their number, we have already, in our former article, given examples of the productiveness of wheat and barley, and described the peculiar structure by which, in the family of the grasses, this productive power may be almost indefinitely augmented. M. Dodart prosecuted the same inquiry on trees. He selected an elm, which, in the fifteenth year of its growth, he calculated to produce, in one season, 329,000 seeds. Supposing this tree to live 100 years, and its mean fecundity, for its whole life, to be taken at 329,000, this number, multiplied by 100, will give 32,900,000 as the number of seeds produced, through its whole life, by the single seed of an elm. But suppose further, says Du Hamel, all these seeds to be planted, and each to produce a tree as fruitful as its parent, and so on from generation to generation ; then, calculating the produce of each of these trees during 100 years, we shall have an increasing geometrical progression, of which the first term will be one ; the second, thirty-three millions ; the third, the square of that number ; the fourth, its cube ; and so on to infinity ; a fecundity which, in the revolution of ages, would be sufficient to cover the whole surface of the earth with one species of plant.

But propagation by seeds is not the only mode by which plants are multiplied. With the exception of some trees, as the pine and fir, which do not shoot afresh when they have been lopped, except when very young, most vegetables, continues the same author, contain in all parts of their branches, their trunk, and even roots, germs which do not develope unless rendered necessary by the retrenchment of their boughs. Thus, if an elm be headed, and its smaller branches removed, its trunk and larger branches will, in the following spring, be covered with new productions, which never would have appeared if the first branches had not been removed. At whatever part or height the tree is headed, new shoots spring forth. The whole tree, therefore, from the root to the extremities of the branches, is filled with germs (or rather, we would say, endowed with a capacity of producing them), when the parts previously existing receive such injury as to render these new productions necessary to supply the place of the former.

Roots also possess this capacity of producing shoots as well as the branches. If the root of the elm be exposed, with certain precautions, to the air, it puts forth young branches ; and many creeping roots, when they come into light and air, produce branches, which, by transplantation, form individual trees. A sprig of willow, when both its ends are thrust into the earth, yields rootlets from both, while the intermediate portion pushes forth leaves into the air ; and the leaves of certain vegetables, as those of *Bryophyllum calycinum*, are capable, in proper circumstances, of producing entire plants. We may therefore say, adds Du Hamel, that there is perhaps no point of the surface either of the branches, the stem, or the root, which does not contain a germ, ready to develope itself when circumstances shall arise wherein this development may be useful to the parent tree. Nay, more, continues the same author, there is not perhaps any point on the branches, the stem, or the root, from which rootlets may not spring, when the conditions required for their development shall be fulfilled. If the root of a species of *campanula* be cut into pieces, and these pieces be put into the earth, each piece will produce both roots and stems. Of these concealed germs, dissection indicates no trace, until they become sensible in the progress of their development. From whence do they proceed? From the vessels or the cells? Or are they formed by the sap? Do they exist in a form invisible to us before the tree was headed? This, says he, is pure conjecture, although it is true, that if this operation had not been performed, the sap would have continued its course in the parts already formed, and would not have aided in developing the germs of which we speak. But not to abandon ourselves to imagination, it is sufficient, he adds, to have shown the immense fertility of vegetables, first, by seeds, and, secondly, by invisible germs, of which but a small number of analogous facts are to be found in the animal kingdom. In these remarks, Du Hamel, the Haller of vegetable physiology, evidently leans to the doctrine of pre-existing germs, which at one time so much occupied the attention of naturalists; but of which he ultimately disposes, with that good sense and real candour, which are not less admirable in all his writings than the talent and information which they every where display.

CHAP. III.—OF THE VITAL POWERS, SECRETIONS, SPONTANEOUS MOTIONS, SLEEP, DECAY, AND DEATH OF PLANTS.

ART. I.—*Of the Vital Powers.*

Such is a brief outline of those vegetable functions which comprehend the evolution, growth, and reproduction of plants. In the description of these functions, we have endeavoured to keep within the limits of observation and experiment; and, in reasoning from the facts derived from these sources, we have adhered strictly to explanations, which apply only to the *physical* constitution of plants. But we are aware, that, to accomplish these physical changes, not only is a particular structure required, but that structure must be endowed with the property or principle that distinguishes living organized beings from dead and inorganic matter. Without embarrassing ourselves with inquiries into the nature and origin of life, we are content, on the present occasion, to seek it only in its effects; to regard it as a power or property not less essential to the constitution of living matter, than gravitation is to that of dead matter; and, rejecting all speculation about its nature, to study only the physical conditions required for the display of its operations, and, as far as we are able, trace the laws by which those operations are regulated. "It is not," says Dr. Franklin, "of much importance to us to know the manner in which Nature executes her laws; it is enough, if we know the laws themselves. It is of real use to us to know that china, left in the air unsupported, will fall and break; but how it comes to fall, and why it breaks, are matters of speculation. It is a pleasure indeed to know them, but we can preserve our china without it."

Beside the evidences of a living power in plants, derived from the ordinary phenomena of growth and reproduction, the function of secretion by which growth is sustained, and various new products formed, deserves more particular notice. Other evidences of this power have been drawn from the various motions exhibited by the roots, leaves, flowers, and fruits of plants; and also from the phenomena of infancy, maturity, and old age, which they exhibit in the successive periods of their existence. To enable them to execute these different functions, and exhibit these phenomena, some physiologists have pushed the analogies between plants and animals to an unwarrantable extent; and, in addition to all the attributes connected with growth and reproduction, have endowed plants not only with irritability but with sensibility, instinct, perception, and volition. In ascribing to them these attributes, more attention seems to have been given to a supposed correspondence in effects, than to a real agreement in the structure and functions of organs. Neither has any very nice distinction been taken between what may be due to physical agents, acting on vegetable organization, and what, from our present inability to explain on *physical* principles, we are too apt at once to attribute to what are called *vital* principles or causes. It is only, however, where physical explanations altogether fail, that it is allowable to resort to the mysterious aid of vital causes: and as the natural philosopher, in treating of inanimate matter, assumes gravitation as a fact, and, without investigating its nature, proceeds to describe the laws of its action; so the physiologist, in studying living bodies, may regard life, and direct his inquiries rather to the laws by which it acts, than to the nature or principle of its action.

ART. II.—*Of Secretion.*

By secretion is understood the separation of a peculiar matter from the general mass of fluids by some particular structure, and which may either retain its primary condition, or pass into a solid state. Though the mass of fluid from which secretions are produced be one and the same, and the secreting organ, as to external conditions, be often in the same circumstances, yet the matters secreted differ greatly from each other, which difference probably arises from variety of structure in the secreting organs. Thus, an essential oil is found only in the rind of the orange, a fat oil only in the kernel of the almond, and so with regard to other secretions which exist only in particular parts. Besides the acids, alkalis, earths, and metals, which, though of a mineral nature, are more or less constantly found in plants, chemists enumerate about forty products of vegetation, which possess distinct chemical characters; and of many of these products numerous varieties exist. As none of these substances can be detected in the common sap, they must have been elaborated by the specific organs of vegetables, under a process of secretion. By what peculiarity of structure, or of function, these organs are enabled to produce such remarkable chemical changes in the common sap, is quite unknown; neither do we know how much is to be attributed to the action of the organ itself, or to the reaction of the several ingredients on each other, or to the influence of external agents.

Of these secretions, the most important is the *cambium*, the fluid employed directly in vegetable nutrition and growth. By the changes which the common sap undergoes in the leaves, the proper juices of plants are formed. These juices differ greatly from each other both in their sensible and chemical qualities. It is from them that the cambium is directly formed by a process of secretion, and in all plants is said to possess nearly the same characters. It is a mucilaginous fluid, without colour, odour, or taste; while the proper juices themselves exhibit all those properties. The proper juices also are contained in the vessels, and flow out when they are divided; but the cambium transudes rather than flows, and that only in places where new parts are to be formed. Thus, in the pine, says Mirbel, while the proper or resinous juice flows in the large vessels, the cambium transudes beneath the *liber*; and similar observations on the fig show that the cambium is entirely distinct from the proper juice. The cambium, then, we must regard as a *secretion*, separated from the proper juice by the vascular structure of the liber or alburnum, when and wheresoever it is required to support nutrition and growth. Hence, in an experiment of Du Hamel, when a piece of the bark of a peach tree was engrafted on the wood of the plum, the new wood, formed beneath the bark, was white like that of the peach, not red like that o the plum. Of the other secretions of plants, which, fo reasons already assigned, are found chiefly on the *externa* parts, as the leaves, flowers, fruits, &c., the number an di rsity are very great. They are probably formed in each in ance, by peculiar and appropriate organs, but in what m ner is quite unknown.

Art. III.—*Of the Spontaneous Motions of Plants.*

lthough plants, as is well known, possess no locomotive po er, yet, in different parts, they often exhibit what are de ned spontaneous movements. In cloudy weather th ugh the day, and always towards evening, many plants, at rtain hours, close their leaves and flowers. Bonnet re rked, that the leaves of certain plants approached by th superior surface when the sun shone; but as he decli d or set, they fell down, and, even in some instances, ap oached by their inferior surface. If heat was applied to aves thus closed, they would open and fold back in a co rary direction: and, on the other hand, if moisture was ap ied to leaves that had been folded by the sun's heat, th also would open and fold back as from dew. In these ex nples, the different conditions of heat and moisture seem ve much to influence the movements of the leaves. In lik manner, the stalks of many fruits change their office un r the different conditions, with respect to moisture, that ac mpany the ripening process: for under the desiccation wh h then occurs, many of them, says Du Hamel, exercise m ements not unlike those of muscular action, and are th eby enabled, in some instances, to scatter their seeds.

e have already described many important effects produ d in plants by the direct action of light, and have now to tice the influence which it exerts on their movements. If pl ts be confined in a chamber, where there is but one wi low, all the younger shoots will forsake their perpendicu r direction and make towards the light. In like manner, a oung tree, when growing in the midst of older ones, pu ies rapidly upwards, till it reaches the height of those th surround it, when it ceases to grow in height, but augm ts in size: or, if a young plant be made to grow in an op que vessel pierced with holes which admit the light, the sh ts which it puts forth will be directed towards the holes. So e plants appear to follow the sun more or less distinctly in is course from east to west. Over these movements, Be net ascertained that neither heat, nor humidity, nor ai had much influence; so that the sun, says Du Hamel, in using these motions, acts more by his light than by his he .

ut there are other movements, proper to certain plants, or particular parts of them, over which light exerts little or o power. Many observations have been made on the m ions of the sensitive plant by Hooke, Du Hamel, and ot rs. The latter author remarks, that the movements of th plant do not depend essentially on light or heat; for if ke in a green-house, it closes its leaves early in the evenin before the sun has withdrawn, and while the temperatu is yet high; or if placed in perfect obscurity, it still co inues to open in the morning, and close in the evening as efore. If, during its expansion in the early part of the da it be gently touched, its leaves partially close, but soon re ver their former state. Mere touch, however, without ag ation, does not produce motion; for the leaves may be pr sed between the fingers, without causing motion, if no ag ation be given. With proper address, it is possible, sa Du Hamel, to divide the mid-rib of a leaflet, without ex ting motion in the other leaflets, or even in its own fo les; nor does motion follow the puncture of a needle, if l agitation be avoided. The time required for a branch, th has been touched, to resume its former state, depends on he vigour of the plant, the hour of the day, the season, & ; and the order in which the parts re-establish themse es likewise varies.

he motions of this plant seem to depend much on pecu arity of structure. From a branch proceed the branchle that bear the leaves. These leaves are formed of a common petiole, which at its extremity terminates in four conjugate leaflets, each of which has a mid-rib, furnished with a certain number of folioles. In the movements of this plant, the branchlets are so articulated with the branch, that they move on it in the manner of a hinge. The common petiole of the leaves has a like movement; and lastly, each foliole moves on its proper stalk to apply itself to the opposite foliole. This peculiarity of structure explains why agitation is so necessary to the movements of this plant; and why it bears such great violence without moving, if no agitation be employed to excite motion in its several articulations; so that it is principally in the articulations, says Du Hamel, that the sensibility of this plant resides. He adds, that, when this plant closes, it is not through weakness, but by a sensible contraction, which resists any attempt to replace it in its former state. Dutrochet accounts for the motions of the sensitive plant by the distension and contraction of the upper and lower portions of the swellings which are met with at the base of the petiole and of the leaflets.

In certain flowers spontaneous movements take place at the period of fecundation. The stamens of the barberry approach towards the pistil on the slightest irritation, as do those of the sun-flower and other plants. During the night, the petals of may-flowers close, and thereby protect the stamens and pistils; but they cease to do so after fecundation is effected. The water-lily is said to bear its flowers on a foot-stalk under water; and when the flowering season arrives, the stalk rises through the water, till the flowers reach above the surface. The flowers then expand, and the anthers burst and discharge their pollen on the stigma in the usual way. About four o'clock in the afternoon, the expanded flowers close, and the stalk then lies down either upon or under the water. The next day it rises, as before, and continues to do so daily until fecundation is completed, when it sinks beneath the surface, and there remains to ripen its seeds. Other spontaneous movements are exhibited by claspers and tendrils in seeking support from neighbouring bodies, and by roots in the directions which they take in search of food.

Unable to assign physical reasons for these and similar phenomena, some naturalists, guided by vague analogies drawn from the animal kingdom, ascribe such movements in vegetables to sensation and perception, by which they not only *feel* their wants, but *perceive* the best modes of gratifying them; and in the performance of the actions necessary to accomplish their objects, they are, according to some, directed by Instinct, and, according to others, by Volition. Such modes of reasoning not only afford no explanation of the phenomena described, but supersede all necessity for it; and are apt, therefore, to beget a conceit of knowledge where ignorance alone prevails. In reference to such attempts at explanation, Du Hamel well observes, that "every peasant has remarked the fact, that the radicle of the seed tends always towards the earth, and that the plume rises in the air. If we ask of them why one part thus strikes into the earth, and the other seeks the air, they give the fact for a reason, by replying that the one part strikes down because it is the root, and the other ascends because it is the stem. And let us not smile too complacently at these modes of expression; for we ourselves use them every day when we raise questions about things which are unknown to us. Do we not say that a stone falls because of its gravity? And those who give for a reason that it is attracted by the earth, do not satisfy the real philosopher, who never is content with simple terms void of meaning. To me it seems both more simple and more honest to make at once a confession of our ignorance."

Art. IV.—*Of the supposed Sleep of Plants.*

Some writers, deeming plants to possess voluntary power, have from thence inferred that they require sleep. We have no proof, however, that they possess any such power; nor that, in the exercise of their ordinary functions, they experience that fatigue and exhaustion which renders sleep necessary to their restoration. All the spontaneous movements of vegetables previously described, seem to arise from the operation of physical agents, conjoined with those inherent properties which belong to them as living beings. These agents act variously on different plants; and hence some close their leaves and flowers from the abstraction of heat or moisture, and others from the exclusion of light; and this at various periods of the day, as well as through the night. Other plants exhibit spontaneous movements only in the flower, and at the season of fecundation, when suitable conditions of the atmosphere prevail; and though, in some instances, these motions continue for a time after the conditions required for their display may have been withdrawn, yet we must ascribe such motions rather to habit than to any thing that partakes of the nature of volition.

The diminution or suspension of action through the night which occurs to plants that inhabit temperate climes, cannot be received as a proof of sleep, induced by the exhaustion of the vegetative powers; for even in such climes, vegetation, in favourable seasons, proceeds often by night as well as by day. In climates still more favourable, the same plants which with us produce fruits only once a-year, yield two or more crops; and in Norway and Lapland, where the sun, at certain periods, continues almost constantly above the horizon, the whole period between seed-time and harvest sometimes occupies only about fifty days. In such cases, little or no suspension of the vegetative functions can have taken place; nor have we the smallest reason to believe that the continued exercise of them is followed by fatigue or exhaustion sufficient to require sleep. What, therefore, has commonly been denominated the "sleep of plants," we can regard only as a diminution or suspension of the vegetative functions, arising from the abstraction, more or less complete, of those external agents, whose presence is essential to their full operation and display.

Art. V.—*Of the Decay and Death of Plants.*

But whether the functions of vegetables unceasingly continue or be occasionally suspended by the abstraction of the conditions necessary to their exercise, all plants submit at length to the same general law, and die, either in whole or in part, when the great purposes of their existence—those, namely, of growth and reproduction—have been accomplished. Some plants speedily arrive at maturity, and having produced their seeds, die altogether; others flourish for one or two seasons, and then decay and perish; and others again die only in part, after having produced their seeds, and also a new series of buds to continue their growth and fructification. In the progress of our inquiry, we have seen that, in every stage of vegetation, certain organs fall into decay after having fulfilled their allotted functions. Thus the tunics of the seed perish beneath the soil, after having yielded their nutrient matter to carry on the evolution of the embryo; and those cotyledons which rise into the air, decay also, when the radicle has taken its proper hold of the soil, and the leaves are sufficiently developed to execute their appropriate functions. So likewise the petals, the stamens, and pistils of the flower, rapidly fade and fall as soon as the important function of fecundation is effected; the fruits next drop when they have reached maturity; and lastly, the leaves, even of perennials, when their allotted functions have ceased, decay and fall like those of annual plants.

To account for this *fall* of the leaves, many hypotheses have been proposed. Some have ascribed it to defective transpiration, and consequent accumulation of juices in the vessels; others to an inequality of growth between the stem and the petiole of the leaf, during the progress of vegetation; others to the desiccation of cellular tissue, supposed to exist at the insertion of the petiole with the stem; others to a simple sloughing of worn-out parts; and by others, the fall of the old leaf has been attributed to the growth of the new bud. In all the examples enumerated above, of the decay and fall of cotyledons, flowers, and fruits, the organs ceased to execute their functions, when the purposes of their existence were accomplished; and such we must regard as the general law that determines the death of the leaves. In some instances, the death of parts seems to be hastened by the diversion of nutrient matter from the older organs to the new parts which are subsequently developed, as is exemplified in the decline and fall of the stamens and pistils from the growth of the ovary after fecundation; but, in other instances, as in the death of annual plants, no such acting cause is apparent, and nothing remains to account for the event that occurs, except the character of duration, more or less extended, which was impressed on the plant at the era of its formation.

But from whatever cause the deciduous organs of plants cease to perform their functions, the immediate cause of their fall seems to vary in different vegetables, and to depend often on accidental circumstances of climate, &c. In some instances, the growth of the young bud seems to occasion the fall of the leaf. Thus, though the leaves of the oak die and become dry in autumn, they do not, says Du Hamel, fall till spring, when the buds begin to open, and the new leaves to appear. In other instances, the fall of the leaf seems to be connected with the exercise of the transpiratory function; for plants which transpire largely, soonest lose their leaves, and hence evergreens, which transpire little, retain their leaves longest. Even if an evergreen be engrafted on a deciduous tree, it still retains its leaves after those of the stock have fallen. Sudden changes of temperature and humidity in the atmosphere, frequently promote the fall of leaves. Thus, in autumn, when rain succeeds to a white frost, the leaves sometimes rapidly fall. So, likewise, it sometimes happens, that the too great heats of summer dry up the leaves; and then also, if warm rains follow, the dried leaves fall and new ones succeed, which continue longer than those of spring. On the other hand, leaves equally fall, though not so speedily, when the winter is mild; and in conservatories, where a regular temperature is kept up, deciduous plants lose their leaves in spring, when the new ones shoot forth. Certain accidents or diseases, however, as lightning, or the eruption of the proper juice from its vessels, or a peculiar disease which separates the bark from the wood, sometimes kill a tree suddenly; and then, says Du Hamel, though the leaves become dry, they adhere strongly to the branches. These facts show, that, while the natural *death* of the leaf is to be sought in the specific nature and constitution of the plant to which it belongs, its *fall* sometimes depends on the growth of new buds; or on variations in the motion of its fluids; or on sudden changes in the temperature and humidity of the atmosphere; and sometimes, probably, the period of the fall is determined by a difference of texture in the fibre of the plant itself.

The duration of the stem or trunk, after the leaves have fallen, is very different in different plants. In many herbs the stem dies at the same time, or shortly after the leaf; but in some trees, the life of the trunk is prolonged through many ages. The Gentleman's Magazine for 1762 contains an account of the age of a chesnut tree, then growing at Tamworth in Staffordshire. This tree, it is said, was, at that period, probably the oldest, if not the largest, in England, being fifty-two feet in circumference. Its period of rising from the nut may be fixed at the year 800, in the reign of King Egbert. From that date to the reign of Stephen is 335 years, at which time it was fixed on as a bo ndary or landmark, and called by way of distinction, the *Great Chesnut Tree of Tamworth.* From the first yea of Stephen, anno 1135, to 1762, is 627 years; so that its ntire age, at that period, was 962 years. It bore nuts in 59, from which young trees were raised. In this tree, the fore, the faculty of producing seeds remained at the age of more than 950 years; but whether this faculty contin s through the entire life of such trees is not known. In annals, we know that life ceases in the whole plant soon aft reproduction has been accomplished; but the observations of Mr. Knight seem to show that, in certain trees, as those of the apple and pear, the reproductive powers cease before those of vegetation. The death of plants at such various ages, yet occurring at the same age in plants of the same species, suggests the belief that a period, beyond which life cannot extend, was assigned to each species at the era of its creation, and that this character of duration, like the others peculiar to the species, is transmitted through all succeeding generations. (Q.)

EGETIUS RENATUS, Flavius, a Latin writer, flo ished towards the close of the fourth century. His tre ise "De Re Militari," he inscribed to the emperor Valen nian the Second, who was assassinated in the year 393. He ppears to have been a man of rank. Raphael Volaterra s styles him "Comes Constantinopolitanus," and some ma uscripts of his own work describe him in a similar manner In the older editions, his treatise is divided into four boo s; but Scriverius, on the authority of certain manuscr ts, divided it into five. The authors whom Vegetius pro esses to follow are Cato, Celsus, Frontinus, and Paternu together with Augustus, Trajan, and Hadrian, in their con itutions, or legal enactments. He has thus collected a luable mass of materials; but Lipsius has remarked tha he confounds the customs and practices of his own wi those of former ages.

n edition of his work, supposed to be the first, appeared nder the title of "Epitoma de Re Militari." It is in fol without place or date, but, according to conjecture, wa printed at Utrecht about the year 1473. There is anoth undated edition in quarto, and a third in folio. After va us intermediate editions appeared that of F. Modius, Co n. 1580, 8vo. It was followed by two editions contai ng the elaborate commentary of Stewechius, Antverp. 15 , 4to., Lugd. Bat. 1592, 8vo. His commentary, toge er with that of Modius, is to be found in the edition of Sc verius, Lugd. Bat. 1607, 4to. These three, like most of e editions, include Frontinus and other ancient writers on military affairs. The text of these authors, with the no s of Scriverius, was reprinted in 12mo. at the same place in 33 and 1644. An edition of Vegetius, containing select no s of Stewechius and Scriverius, with those of the editor, an a French translation, was published by N. Schwebelius, N mbergæ, 1767, 4to. Another, containing the annotatio of various critics, appeared long afterwards, Argent. 18 , 8vo. The work has been translated into several mo ern languages. There is an early English version by Jo Sadler, Lond. 1572, 4to. And a more recent translat n was published by Lieutenant John Clarke, Lond. 17 , 8vo.

EGETIUS RENATUS, Publius, is sometimes confo ded with the writer noticed in the preceding article. H s the author of a work on the veterinary art; "Artis Ve rinariæ, Sive Mulo-medicinæ, libri IV." Basil. 1528, 4t This is the *editio princeps;* and it was followed by th edition of Sambucus, Basil. 1574, 4to. Vegetius was ins ted by Gesner among the "Scriptores Rei Rusticæ ve res Latini." Lipsiæ, 1735, 2 tom. 4to. There is a se rate edition, of which the title bears, "curante Jo. M hia Gesnero." Mannhemii, 1781, 8vo. But it merely co ains a reprint of Gesner's text, without his annotations. O this work an English version was published "by the au or of the translation of Columella." Lond. 1748, 8vo.

EGLIA, an island in the Adriatic part of the Austrian pr ince of Trieste, in the bay of Quarnaro. It is, includin the small island Plaunich, about ninety square miles in ex nt, and contains a city, three market towns, and fourteen villages, with 10,414 inhabitants. The island is mountainous and rocky, and on the north and east sides very barren, but in the other parts has a fertile soil, yielding abundance of fruit and of wine, but not sufficient corn. Some good oil is made, and the fishing is an important source of wealth. The capital, of the same name, is the seat of a bishop, who has a palace and a cathedral. The export of wine is the chief trade. The harbour is both small and shallow. The inhabitants do not exceed 1400. Lat. 45. 3. 20. Long. 14. 32. 40.

VEII, a city of ancient Etruria, and long the powerful rival of Rome; distant about 100 stadia, or twelve miles, to the north-west, and situated on a high and steep rock. It was taken after a siege of ten years by Camillus, six years before the taking of Rome by the Gauls. The spot on which it stood lies near Isola in St. Peter's patrimony.

VELARIUS, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain in the prince's apartment, as that of the chancellor's was at the entry of the ballustrade, and that of the ostiarii at the door. The velarii had a superior of the same denomination, who commanded them.

VELE RETE, a cluster of rocks in the eastern seas, to the south of the island of Formosa. Long. 121. 30. E. Lat. 21. 55. N.

VELITES, in the Roman army, a kind of ancient soldiery, who were armed lightly with a javelin, a casque, cuirass, and shield.

VELLETRI, a city of Italy, in the papal territory, and the district of Tivoli. It stands on the declivity of the Albanian hills, has decayed walls and dilapidated towers, but is the seat of a bishop. It is ill built, but has a fine market place, a cathedral, with several other churches, nine monasteries, and two nunneries. Here is a fine museum belonging to the family of Borgia. The inhabitants are 9740, chiefly employed in agriculture and in making oil. Lat. 41. 41. 16. Long. 12. 39. 25. E.

VELLORE, a celebrated town and fortress of the south of India, province of the Carnatic, formerly the capital of a small district of the same name. It was once a port of great importance, as it commanded the main road leading to the Upper Carnatic, from the valley of Peniambady, which is the most direct route to and from the Mysore. It is strongly fortified, the walls being built of very large stones, with bastions and round towers at short distances. A fausse bras lines the wall between them, and, with its embattled rampart and small overhanging square towers, produces a very handsome effect. The whole fort is surrounded by a deep and wide ditch, cut chiefly out of the solid rock, except at one entrance, where there was a causeway. Besides the usual defence, the ditch contains curiosities of rather an extraordinary character, namely, alligators of a very large size. The fortress, though strong, is commanded by the surrounding hills. It was first taken by the Mahometans in 1646, and afterwards by Sevajee in 1677. Subsequently it came into the possession of the nabob of Arcot: and in 1782 was besieged by the whole army of Hyder, when it was relieved by Sir Eyre Coote. After the capture of Seringapatam in 1799, it was fixed upon as the state-prison of Tippoo's family, consisting, besides his brother, of twelve sons and eight daughters, with a numerous progeny, and an innumerable crowd of women. On the 10th July 1806, a serious mutiny took place among the garrison, principally composed of native troops, who endeavoured to murder all the Europeans they could find. The ostensible cause of the mutiny was a change of dress; but it was strongly suspected that it was instigated by the sons of Tippoo, who were in consequence removed to Bengal, where they remain under a liberal restraint. Since the conquest of Mysore, this fortress has lost much of its consequence, and its fortifications will probably be allowed to fall to decay. The district is included in the collectorship of Arcot. Travelling distance from Madras 88 miles west by south; from Seringapatam 202 miles. Long. 79. 13. E. Lat. 12. 55. N.

VELLUM, a town in the Southern Carnatic, seven miles south-west from Tanjore. Long. 79. 7. E. Lat. 10. 40. N.

VELLUM, is a kind of parchment, that is finer, evener, and more white than the common parchment. The word is formed from the French *velin*, of the Latin *vitulinus*, "belonging to a calf."

VELOCITY, in *Mechanics*, swiftness; that affection of motion whereby a moveable is disposed to run over a certain space in a certain time. It is also called *celerity*, and is always proportional to the space moved.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue. The nap or shag, called also the *velveting*, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channelled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp.

VENCATIGHERRY, a town in the province of the Carnatic, eighty-two miles north-west from Madras. Long. 79. 32. E., Lat. 13. 56. N.

VENDÉE, a department of the south-west of France, formed out of the western part of the ancient Lower Poitou. It extends in north latitude from 46° 19′ to 47° 7′, and in east longitude from 0° 44′ to 2° 32′. It is bounded on the north by the departments of the Lower Loire and Mayenne-Loire, on the east by that of the two Sèvres, on the south by the Lower Charente, and on the west and south-west by the ocean. Its shape is nearly a square, and it extends over 2662 square miles. It is divided into three arrondissements; and those into thirty cantons, comprehending 294 communes, and contained in 1836 a population of 341,312 persons, who, with the exception of a few scattered families, adhere to the Catholic church. They have been commonly described as hospitable, good tempered, faithful to their engagements, simple and antique in their manners, averse to any changes in their customs, and attached almost to superstition to the doctrines and observances of the Romish religion. The noble families, the ancient chief proprietors of the land, were only distinguished from the rest of the inhabitants, their feudal tenants, by a greater degree of cleanliness in their dwellings, their clothing, and their food; but were equally resolute in their opposition to the changes operated by the Revolution, and the whole were alike distinguished by their bravery, their perseverance, and their endurance of those hardships which they brought on themselves by the political party they embraced. The civil war whose name was derived from this department, extended to all the district round it, in a greater or less degree; and its long continuation may be attributed to the peculiarities of the country, and its capabilities for defensive warfare, as much as to the resolute courage of the population.

The surface of this department is an extensive plain, uninterrupted by any hills except by two chains in the eastern part, separated from each other by a valley about two miles in breadth, none of the points of which exceed 400 feet in height. This more hilly part is distinguished by the name of the *Boccage*, on account of the great number of trees and bushes with which it is covered, and it was the chief theatre of the long and bloody civil war, whose traces are even now far from extinct. The western and southern parts consist of the *Marais* or marsh land, which contains excellent pasture land, protected by embankments and drained by artificial canals. Another part along the coast, including the islands Bouen, Dieu, and Noirmoutier, contains much fertile soil, of which about two-thirds are used as pasture, and one-third produces corn.

The rivers are of no great importance. The chief of them, from which the department takes its name, is a moderate stream issuing from the Sèvres, and falling into the Mortaise. It supplies water to several small canals, and is navigable for barges carrying sixteen or eighteen tons from Fontenoy, where it is about 120 feet in breadth. The Mortaise is navigable through its whole extent for small vessels, and enters the sea through several marshes near to the city of Aiguillon, in the bay of that name. The other streams, the Lay, the Isle, the Ausance, and the Pairay, with some others, are navigable but a short distance from their respective mouths.

The agriculture is in a low state. Little of the land is cultivated by the proprietors, but chiefly by metayers, who divide the gross product in equal parts with their lords. Except in the lands on the three principal streams, the common rotation of grain is, two corn crops after a year's clear fallow. The ploughing is performed almost exclusively by oxen. The wheat is good, and much of it is converted into flour for exportation to the French West India islands. The other kinds of corn produce good crops, and of late years the cultivation of potatoes has been introduced and extended. The breed of horses is of an indifferent kind, but many of them are used to mount the hussar troops. The black cattle are numerous, but the sheep very few and not good, though of late years attempts have been made to improve the race, as regards the fineness of the wool, by crosses with Spanish rams. Silk was once a part of the agricultural pursuits; but during the disturbed state of the country, the planting of mulberry trees was neglected, and some years must pass before the produce can amount to its former quantity. Wine is extensively made, the quality is good, and much of it will bear to be kept a long time without the aid of brandy. The manufactures are few. The most considerable are those of linen, but some woollen cloths for home use are made. The department furnishes two deputies to the Chamber of Representatives. It is included in the tenth military division, and is in the diocese of Montauban.

VENDOLA, the most eastern of the Admiralty Islands, about three miles in circuit, covered with cocoa trees, and very populous. It is so surrounded by rocks, that it is almost inaccessible to boats. Long 148. 9. E. Lat. 2. 14. S.

VENDOME, an arrondissement of France, in the department of the Loire and Cher. It is 655½ square miles in extent, comprehends eight cantons divided into 110 communes, and in 1836 contained 77,760 inhabitants. The capital, a city of the same name, stands on two islands in the river Loire. In 1836 it contained 8206 inhabitants, employed in making gloves, hosiery, cotton goods, paper, and the several kinds of leather. Lat. 47. 47. 19. Long. 1. 1. 38. E.

VENEERING, VANEERING, or *Fineering*, a kind of marquetry, or inlaying, by which several thin slices or leaves of fine wood, of different kinds, are applied and fastened on a gr und of some common wood. There are two kinds of inla ng; the one, which is the more ordinary, goes no farthe han the making of compartments of different woods; the her requires much more art, and represents flowers, bir and the like figures. The first kind is what we pro perl call *veneering;* the latter we have already described und MARQUETRY.

e wood intended for veneering is first sawed out into slic or leaves, about a line thick. In order to saw them, the locks or planks are placed upright in a kind of vice or saw g press, the description of which may be seen under the ticle just referred to. These slices are afterwards cut int lips, and fashioned divers ways, according to the de sig proposed; then the joints being carefully adjusted, and the eces brought down to their proper thickness, with seve ral anes for the purpose, they are glued down on a ground or l ck of dry wood, with good strong English glue. The pie s being thus joined and glued, the work, if small, is put in press; if large, it is laid on the bench, covered with a boa , and pressed down with poles, or pieces of wood, one enc f which reaches to the ceiling of the room, and the oth bears on the boards. When the glue is quite dry, they tak it out of the press and finish it; first with little planes, the with divers scrapers, some of which resemble rasps, wh take off dents left by the planes. When sufficiently scr ed, the work is polished with the skin of a sea-dog, wa and a brush and polisher of shave-grass.

ENEZUELA, one of the provinces which composed th republic of Colombia, but which has recently been er ed into an independent republic, is situated between 2° d 12° north lat. and 60° and 73° west long. It is bo ded on the north by the Caribbean sea, on the east by British Guiana, on the west by New Granada, and on e south by Brazil. This country was named Venez ue by the Spaniards, from the towns of the Indians, built on he small islands in the lake Maracaibo, having a re sem lance to Venice.

he mountains of Venezuela, which form a part of the gre t branch extending from the west to the gulph of Paria, div e the lands of the coast from the plains of the valley of e Orinoco. It is on these rivers that there is such a di sity of climate, that a traveller may observe the fruits of e tropics luxuriating at a short distance from those of Eu pe. The surface of the ground is rent in every direc tic by the force of subterraneous convulsions. To the so h of this chain, the llanos, or plains, which stretch to th Orinoco, are inhabited solely by herds of cattle tended by ulattoes. The climate of Venezuela is modified ac co ing to the situation of its districts. On the coast and in he plains a scorching heat prevails, accompanied in th latter with deluges of rain. In the mountain valleys th ir is in general pure and mild, and in some of the more el ated parts even cold.

he soil of Venezuela is fertile, and yields in abundance al he products of the West Indies, besides many which th e islands do not possess. Its chief commercial article is co a, which is inferior to none in the Americas. The other ol cts of cultivation are vanilla, maize, indigo, cotton, sugar, to eco, and coffee. Here also wild cochineal, dyewoods, m icinal drugs, gums, and resins, find that climate which is ost favourable to their growth. The immense plains in th interior feed multitudes of cattle, horses, and mules; ar in the valleys and mountains sheep and deer are nu m ous. All kinds of game are found in this country; and th rivers abound with fish.

he forests produce every species of timber fit for the p oses of the joiner or the shipwright. Cedar is used for th r door-posts, window-frames, tables, &c.; black, red, and ye ow ebony are common; mahogany, brasiletto, and all s s of ornamental woods, are to be found in the greatest a ndance and of the finest quality. The immense forests which overspread the chain of mountains remain unexplored.

For about a century after this country was subdued by the Spaniards, their attention was almost wholly directed towards its mineral productions, and the pearl fishery on its coasts. But being disappointed in their expectations of immense riches from these sources, they at last began to cultivate the soil. They first planted cocoa trees; and so large were the profits from this source, that cocoa alone occupied their fields till a very late period. About the year 1774, indigo began to be cultivated; and immense plains, hitherto desert, were soon covered with this plant, which was speedily followed by cotton, sugar, tobacco, coffee, &c. But notwithstanding the aptitude of the soil, and the genial nature of the climate, agriculture still languishes in these fine regions, partly from want of enterprise and industry, and partly from too great a confidence in the prolific nature of the soil.

On the plains of Venezuela the rainy season commences in April and continues till November. The rains fall oftener in the morning than in the evening, and on an average occupy three hours of each day. During this period, the plains nearest the rivers are converted into lakes of immense extent.

The rivers of Venezuela are more numerous than in any other part of Spanish America. Every valley has its stream; and though many of them are not of sufficient size to be navigable, yet all afford ample supplies of water to irrigate the plantations on their banks. The principal of those which run from the mountains of Caraccas and Coro into the Caribbean sea, are the Guiges, Tocuyo, Aroa, Yaracuy, and the Tuy. The Guiges falls into that sea sixteen leagues west of the city of Coro. The Tocuyo discharges its waters twenty-five leagues east of the Gauges, or Gaigues: its source is fifteen leagues south of the town of Curora, at the distance of nearly one hundred miles from the ocean; and it is navigable as far as the village of Banagua, at the distanceof forty leagues from its mouth, its banks furnishing abundance of timber of the largest size, and fit for every kind of building. The Aroa rises in the mountains west of the town of St. Felipe, and enters the ocean at Burburata bay. The Yaracuy enters the Caribbean sea near the latter. The Tuy discharges itself into the sea thirty leagues east of La Guayra; it rises in the mountains of St. Pedro, ten leagues from the capital, and being joined by the Guayra, becomes navigable, and serves to transport the produce of the cultivated plains or valleys of Aragoa, Tacata, Cua, Sabana, Ocumare, Santa Lucia, and Santa Teresa, through which it passes, and which particularly abound in cocoa of the best quality. The following are the more important rivers which rise on the southern side of the chain, and flow to the Orinoco: the Guarico, which receives some of the branches of the Apure, and then following a course parallel to that river, enters the Orinoco by the Rio Mancapra, which flows through the plains of Calaboso; the Portuguesa, which is formed by the union of the two rivers Pao and Barquisimeto, flows through the greater part of Venezuela, and joins the Apure forty miles north-west of its mouth. For an account of the Orinoco, see ORINOCO.

Besides Caraccas, the capital of Venezuela, (see CARACCAS), the principal towns are La Guayra, the port of Caraccas, one of the hottest places in the world; Caro, the principal town of the province of that name, with a population of about 10,000; Porto Cavello, thirty leagues north-east of Caraccas, with a population of 9000; Guanara, ninety-three leagues south-west of Caraccas, with a population of above 12,000; Barquisimeto, 120 miles west-south-west of Caraccas, with a population of more than 11,000; Tocuyo, twenty leagues north of Truxillo, with above 10,000 inhabitants; San Carlos, situate on the small river Aguare, with about

Venezuela.

9000 inhabitants; Araura, situate between two branches of the river Aricagua, with a population of 11,000; Maracay, situate in the rich vale of Aragua, a beautiful and flourishing town, with 10,000 inhabitants; Victoria, on the road leading from Caraccas to Porto Cavello, in the midst of a most productive country; Tulmero, two leagues from Maracay, with 8000 inhabitants; Valencia, sixteen miles south-west of Caraccas, with 15,000 inhabitants; Barcelona, at the mouth of the river Neveri, with 14,000 inhabitants; Cumana, the capital of the province of the same name, with about 20,000 inhabitants; Angostura, on the Orinoco, with 3000 inhabitants.

In 1838	509,239	709,792

In the year 1831, by one of those revolutions which have followed each other in too rapid succession in Spanish America, the extensive country, then called Colombia, was dissevered into three independent republics under the names of Venezuela, New Granada, and Equator. The last of these has already been described under the article QUITO; it only remains that we shortly notice the republic of New Granada. It extends from the equator to 12° north lat., and from 68° to 83° west long.; having Venezuela on the east, Brazil and Equator on the south, the Pacific ocean on the west, and the Caribbean sea on the north.

The cordillera of the Andes crosses the country from north to south, and insensibly decreases in elevation towards the province of Panama. Between 2° 30′ and 5° 15′ of north lat., the main chain separates into three parallel ridges. The eastern, some of whose summits are covered with snow, divides the great river Magdalena from the plains of the Meta. The central ridge separates the Magdalena from the Rio Cauca: this is the most lofty of the three, and rises into the region of eternal snow. The western ridge separates the Rio Cauca from the province of Choco: it scarcely attains an elevation of 4500 feet, and is nearly lost in the province of Panama. For a more particular description, see ANDES.

The rivers are very numerous. The chief of these is the Rio Grande de la Magdalena, a majestic navigable river, of which, however, little is known. It is said to rise about thirty miles east of Popayan, near the sources of the Cauca, in 8° south lat., and after a northerly course of immense length the two rivers unite, after having flowed in nearly a parallel line on the opposite side of the same chain of mountains. Its chief tributaries are the Suarez, the Gallinazo or Sogamozo, the Rio Negro, and the Bogota or Funza. The Meta is a noble river, which rises in the mountain ridge opposite to Bogota, and flowing eastward joins the Orinoco thirty leagues below the cataracts of Atures. Its banks are inhabited chiefly by Indians. The Apure is also a large river, which rises in one of the ridges which diverge from the eastern branch of the Andes, and joins the Orinoco twelve leagues below Santiago. The river Atrato flows into the gulph of Darien, and by it much of the internal produce is exported. But the whole country abounds with rivers and streams to an extent which it would be tedious to enumerate. Every valley has its rivers, large or small, and, if not navigable, at least sufficient to fertilise the ground.

The principal cities have been already described. See BOGOTA, SANTA MARTA, CARTHAGENA, PANAMA, PORTO BELLO, VERAGUA, POPAYAN, MOMPOX, ILONDA, TUNJA, and PASTO, which was destroyed by an earthquake in 1834.

The vegetable productions of the country are nearly the same as those of Venezuela. The soil is exceedingly fertile; the fruits are produced in great luxuriance, and the trees attain an immense bulk.

Its vast forests are infested by numerous tribes of wild animals. Among these the jaguar or tiger, and the American leopard, are very destructive to the cattle. Wild boars, foxes, armadilloes, squirrels, deer, rabbits, and monkeys are abundant, and are eaten by the Indians and Negroes.

The feathered tribes are numerous and beautiful. Among these the toucan with its large bill, the gallinazo vulture, which clears the country of dead carcases, and the macaw, with its beautiful plumage and disagreeable voice, are the most singular.

Providence has dealt out his gifts to this quarter with a lavish hand; but to compensate for this preference over more sterile lands and less genial climates, he has mingled with them evils of the most serious kind,—noxious animals, oppressive heat, furious thunder storms and earthquakes. The insects and reptiles are as numerous as the birds and beasts. Among the insects may be mentioned the centipede, the scorpion, the spider, the pique or jigger of the West Indies; among the reptiles, the rattlesnake, the dart, and the still more venomous coral snake. While the feet of the pedestrian are insecure from the attacks of these creatures, his face is exposed to the venom of the musquitoes. The bed may be surrounded with gauze curtains, to protect the sleeper, but it is of no avail, for another and almost imperceptible enemy finds access through the threads: these are called mantas blancas, from their resembling white cloaks while flying in clouds in the air. In some places bats are so numerous that they cover the street in an evening in clouds, and infest the houses.

The hills and rivers are supposed to have formerly supplied considerable quantities of gold. The gold washings of most consequence are those of the Novita, Zitara, and the river Andegada, in the province of Choco. All the ground between this river and the San Augustin is auriferous. 10,800 marks of gold is the utmost annual produce of the washings of Choco. Here a piece of gold was once found by a negro which weighed twenty-five pounds. Platina is also found in this and the neighbouring province of Antioquia. This valuable metal is discovered in grains in the alluvious grounds between the second and sixth degrees of north latitude. The ravine of Oro, between the villages of Novita and Tado, yields the greatest quantity.

New Granada is divided into twenty provinces, and 110 cantons. The total population, as taken in the first quarter of 1835, was 1,686,038.

On the 31st of August 1835 there were three universities, nineteen colleges, and seven public schools in the republic, attended by 2307 pupils; of Lancasterian schools there were 125, attended by 6741 boys, and five attended by 220 girls; of schools upon the old system, 419, attended by 11,557 boys, and 141 attended by 1605 girls; thus proving that female education must be very much neglected, for while 20,605 young men and boys are attending the schools and colleges, only 1825 girls are receiving instruction in the schools.

ENIAMBADY, a small village of Hindustan, in the Ba amahal province, fortified with a mud wall, 120 miles we south-west from Madras. Long. 78. 42. E. Lat. 12. 42 N. It stands on the banks of the Palar, and contains tw temples of note, the one dedicated to Mahadeva or Si and the other to Vishnu.

ENICE is situated in north lat. 45° 25′ and east long. 12 0′, in the midst of a lagune, or shallow lake, which exter about twenty miles in length from north to south, an about six in breadth, divided from the sea by the two isl ds, or sand-banks, of Malamocco and Palestrina, each ab t nine miles long, but only half a mile in breadth. The city occupies a tract of dry ground about seven miles in circumference, but divided into a great number of islands by canals, the principal of which, the Canale Grande, extends in a great curve through the heart of the town, with a width of 200 feet, and is crossed near its middle by the Rialto bridge, a magnificent structure of marble, consisting of a single arch overtopped by two ranges of shops, which form three roadways. The principal part of the city is, moreover, divided by a still wider canal, that of Giudeca, (which varies in width from about 1200 feet to 2160,) from a long and narrow series of islands, the most easterly of which contains the fine church of San Giorgio Maggiore, built by

Venice.

Palladio. Venice is considered to be one of the finest cities of Europe, though its streets are very narrow and winding, and most of them only calculated for foot passengers, the great thoroughfares being the canals. But in the midst of its labyrinth of canals and streets there are several large piazzas, or open areas, almost every one of which is adorned with a fine church or palace. The principal of these areas is the Piazza di San Marco, a large oblong measuring 562 feet by 232, surrounded with elegant buildings on a regular plan, and terminated at its eastern extremity by the metropolitan church of St. Mark, a singular but splendid combination of the gothic and the oriental styles of architecture. The Piazza likewise contains the campanile or belfry of St. Mark's, a lofty square tower, 316 feet high and forty-two on each side, terminated by a pyramidal top, to which the ascent is formed by an easy inclined plane instead of a stair. Adjoining the church is the Doge's palace, a marble edifice in the Saracenic style; the prisons and other public offices of the late republic of Venice; and in front of the palace is the Piazzetta, which forms the communication between the great piazza and the lagune, and is as it were the state entrance to Venice. On the quay of the Piazzetta are placed two magnificent monolithic granite columns, one crowned with the winged lion of St. Mark, and the other with the statue of St. Theodore, the first patron of the republic. Between these columns is the place for public execution.

Venice is said to contain one hundred and twenty churches, and seven synagogues. It is divided into six quarters, which are subdivided into thirty parishes; each of the smaller islands in the lagune has also its church, generally that of a convent, some houses, and a few trees. There are seven theatres. The principal scientific and literary institutions are, the lyceum, which possesses a rich physical cabinet, and a botanical garden; the two royal and the patriarchal gymnasia; the college of the Salesiane for young ladies; the college for marine cadets; the principal normal school; the section of the Imperial and Royal Institute of arts and sciences, and the Venetian Atheneum, a union of the old learned societies of Venice; the academy or school of the fine arts, whose rooms may be ranked among the finest in Europe, containing a choice collection of casts, a superb picture gallery adorned with the works of the greatest masters of the Venetian school, and a considerable library formed of the most important works relative to the fine arts, and the celebrated collection of original designs of the ancient schools formed by the chevalier Bossi. Although entirely re-organized in 1807, this academy may be regarded as the oldest establishment of the kind, for the statutes of the fraternity of artists which it represents, are of a date anterior to the year 1345. Lastly, we may notice the library of St. Mark, one of the richest in Italy, with a fine cabinet of antiquities and medals, now placed in the great council-hall of the ducal palace. There is, besides, the Cornarian museum, an immense collection of pictures, medals, books, and curiosities of every kind, bequeathed to the city by a noble Venetian of the Cornaro family. The principal public walks of Venice are the Piazza of San Marco, the Piazzetta, and the Riva degli Schiavoni, a long quay leading to the public gardens, which are finely situate at the south-eastern extremity of the city. The great number of bridges, which all have steps, and the narrowness of the streets, render the use of wheeled carriages impossible; but in their stead there is a great number of boats, named gondolas, which form one of the principal characteristics of this singular city.

The most important public institution now at Venice is the arsenal, which is very spacious, being about two miles in compass, and containing workshops of all kinds, large stores of every article requisite for the outfit of ships of war, and a series of halls in which immense quantities of arms and munitions of war are grouped in a tasteful manner. The hall of models contains a large collection of models of all sorts of ships; and in an adjoining chamber there are busts by Canova of Emo, a naval hero celebrated in Venetian history, and of General Galtamelta, a commander of high repute. The same apartment likewise contains a fine model of the Adriatic, with its rocks, cliffs, and islands. The arsenal contains thirty-two covered slips for ships of the line, fifty-four slips for smaller vessels, four large basins, five cannon founderies, a ropewalk 910 feet long, extensive workshops for carpenters, ship-builders, &c. The number of people employed is from 1000 to 1200. Only a few fragments of the celebrated Bucentaur remain. The arsenal, however, is inaccessible to line-of-battle ships, or even frigates with their guns on board; and even when the bulwark of Malamocco, now in progress, is completed, it will only have twenty-four feet water. Venice is the head-quarters of the Austrian imperial navy.

For a number of years after the downfall of the republic, Venice exhibited such symptoms of rapid decay, that many were induced to prognosticate that ere long it would be abandoned, and its foundations again buried in the waters. In 1815, many Venetians entertained a natural and laudable wish for the regeneration of their country; but the force of circumstances prevailed, and Venice continued to be an appendage of the Austrian empire. By commerce Venice had become great; and by new commercial regulations, the people believed that she could again be raised to prosperity. The wish for the establishment of a free port was expressed so generally and so loudly, that the government at length consented; and in 1830, the wished-for object was attained. But though there has been a decided increase in the maritime traffic, yet the magnificent expectations of the citizens have not been realised. Neither have manufactures on an extended scale been yet introduced, though the abundance of low-rented houses and cheap labour seem to offer many advantages. Mirrors, straw-hats, wax candles, catgut, which are the staple productions of Venice, and the like, are articles of trifling importance compared with objects of universal consumption. It is however already a great point gained, that a stop has been put to the diminution of trade and population, which were rapidly melting away. During the last fifteen years, the progress of decay has been arrested, and things are again improving, though but slowly. The Venetians are recovering their ancient habits of prudence and activity; but much yet remains to be done before they can be relieved of the general reproach of indolence. Scarcely any kind of labour in Venice is performed by natives; and many strangers find employment as water-carriers, servants, &c. Even the patricians deem it less disgraceful to enrol their names as paupers than to apply themselves to labour; and, according to Raumer, more idle people are to be seen in St. Mark's Piazza in one day, than in England during a whole year.

All Italy is distinguished for the number of its charitable institutions, and in this respect Venice holds a prominent place. In the city there is one house with accommodation for 700 poor people; while many more have free lodgings elsewhere, and receive pecuniary assistance out of the establishment. There is an orphan-house for about 335 children, a lying-in hospital for thirty-six women, a wealthy institution for the reception of penitent women, an hospital for 1000 patients, a house of education for 90 young girls, a foundling hospital, &c. And the revenues of all these, arising chiefly from endowments, amount to about 580,000 florins, or L.60,000 sterling a-year. The French government united all these institutions and endowments into one, without respect for their origin, their object, or the directions of their founders; but in 1826, each foundation was again placed under a separate administration, the whole being still subjected to the inspection of government. It

18[illegible], daily relief was afforded to 3200 permanent paupers, and occasional relief to 4000. The number of those whose names were enrolled as paupers, and who in the course of one year received occasional assistance in the shape of money, medicine, &c., amounted to 41,300 persons; in another year to 40,782. If to these be added the several institutions for lunatics, sick, orphans, foundlings, &c., it will appear that no fewer than 52,443 persons, or more than one-half of the population of the city, receive charitable assistance. The population of Venice is about 10[illegible]00, without including the garrison, which is inconsiderable. Eight hundred patricians receive a kind of daily wages from the government. The number of foundlings now maintained in the city is stated to be 3338; and for the country districts of Venice, 10,625. There is no want of elementary schools for reading, writing, and arithmetic; and infant schools have recently been introduced.

A railroad has been projected, and is now in progress, to connect Venice with Milan, passing through Padua, Vicenza, Verona, Mantua, and Brescia, a distance of 166 miles, nearly upon one level. The greatest, and indeed almost the only serious obstacle to the execution of the work, is the carrying of the road across the lagune, exceeding two miles of mud and water.

To the north of the city is the small town of *Murano*, whose glass-works were in great repute for several centuries, though their productions are now inferior to those of France, England, and Bohemia; and to the eastward is *San Lazzaro degli Armeni*, an island with a convent inhabited by Armenian monks, who devote themselves to the education of their countrymen, and the cultivation of their national literature. They have published several useful works in their national language, and they issue a weekly journal, which is circulated throughout the East. For an account of the Venetian territory, see LOMBARDY. (C.H.)

VENLOO, a city of the Netherlands, in the province of Limburg and circle of Roermund. It is situated on the right bank of the Meuse, over which is a flying bridge. It is strongly fortified, and is protected by Fort St. Michael on the opposite side of the river. It contains 5740 inhabitants. Its chief trade is by the river, but it has manufactories of needles. Lat. 51. 22. 17. Long. 5. 4. 26. E.

VENTILATION is the art of providing any confined area or apartment with an adequate supply of air, in a condition suitable to the purposes for which it may be required. The air is usually introduced in a stream which maintains a freshness and purity of atmosphere in the place that is ventilated, any contaminated air being withdrawn as the pure air enters.

In numerous operations of nature and of art, and more especially during combustion, respiration, and the decay that attends the putrefaction of animal and vegetable matter, unwholesome products are evolved; and so deleterious are these to animal life, that death is the necessary consequence when they accumulate in a more concentrated form around the person. In a smaller proportion, they produce an endless variety of discomfort or disease, from the most trifling sense of languor or debility to the more violent apoplectic headache, for the time suppressing all attempts at exertion either of mind or body, while on other occasions a slow and insidious action gradually undermines the constitution, and induces a permanent loss of health. In extreme cases death is induced, more or less rapidly, according as the oxygen of the atmosphere is withdrawn, or an impregnation of poisonous gases communicated to it.

The air of respiration is the great *pabulum vitæ:* we draw upon it no less than twelve hundred times an hour, on an average, for nourishment and support, during the whole period of our existence; we consume oxygen, and replace it by carbonic acid; and were it withdrawn from us or changed in its qualities, death would inevitably ensue. The air acts incessantly, not only on the blood as it passes through the lungs, but also on the surface of the body; and disease and death may ensue from an unwholesome atmosphere in contact with the skin, even when the lungs are supplied with pure air. Well attested cases are recorded where severe oppression has attended the action of an amount of impurity so small as from 1-15000th to 1-5000th part of sulphureted hydrogen gas; while the absolute amount of impurity in air tainted by miasma is so excessively minute, that its precise nature, as well as the minuteness of its weight in the most pestilential atmosphere, is unknown.

A supply of a fresh and wholesome atmosphere may accordingly be ranked among the first and most essential necessaries of life. In the atmospheric ocean which rests on the surface of the terraqueous globe, a perpetual movement, *or natural ventilation*, is sustained on a great scale by numerous causes, more especially however by the unequal action of the rays of the sun on the equator and at the poles; the colder air moving along the surface from the poles to the equator, while the warmer air from the equator ascends and proceeds in a contrary direction towards the poles. These great and primary currents are modified in endless variety by the attraction of the sun and moon, the rotation of the earth upon its axis, the relative effect of the land and water, the ever-varying influence of local temperature, volcanic action, meteoric phenomena, more especially the evaporation and deposition of moisture, the electrical condition of the air and of the surface of the earth, and the innumerable changes that attend chemical action in the mineral kingdom, as well as in those that occur in the organic world. The animal and vegetable kingdoms not only contribute to the movement of the air, but are at once the great causes of the most important changes induced upon it, and of its restoration to its former composition; the animal kingdom consuming its oxygen and producing carbonic acid, while in the vegetable kingdom, the great tendency is to absorb carbonic acid and replace oxygen. But where these great movements are interrupted by local causes, or an undue accumulation of vegetable and animal debris takes place, there the due balance is not sustained, pestilential effluvia contaminate the air, and were it not for the wind, the rain, and the impetuous storms which from time to time visit such localities, and the operation of a peculiar diffusive power, in consequence of which no gas can accumulate permanently on the surface of the earth, whatever may be its specific gravity, they would in general become at last as fatal as the valley of death in Java, or the carbonic acid springs in Bavaria, in the grotto del Cano, and other places, which are so notorious for their destructive atmosphere.

In selecting a site either for a house, a city, or any establishment where persons are crowded together, too much attention cannot be paid to its natural ventilation; an aspect towards the south, a dry gravelly soil and moderate elevation, securing efficient drainage and freedom of access to the air, with protection from offensive currents, and an immunity from local impurities, are the great desiderata.

In the open air the temperature is generally under that of the body; and the air expired from the lungs, and also that in contact with the surface of the body, being expanded by the heat which it receives, escapes, from its levity, and a fresh stream is immediately supplied; but when the body is confined within a limited space, special means must be employed to sustain a constant renewal of fresh air.

This artificial ventilation, it is obvious, must be modified and adapted to the peculiar circumstances of each individual case, and the state of the external air which is supplied. It is a subject therefore of great extent, and as various in its details, as the climate in which man lives, the habitations in which he dwells, the occupations in which he is engaged, the food upon which he lives, the means of protection against heat and cold which he can command, and the peculiarity of constitution which he may present. We shall therefore content ourselves, in the remaining space allotted to this article, by pointing out the leading facts connected with the more prominent objects which it includes in reference to the frame of man. It must not however be forgotten that this branch of science is as yet in its infancy, that the history of numerous points connected with the motion of aerial fluid, is only beginning to be minutely investigated; and that, in a practical point of view, it is as yet so imperfectly attended to, that it is impossible to turn to any city without seeing discomfort, disease, and even death, from time to time induced by ignorance of the laws of ventilation; and in assemblies of every variety, the whole audience is not only too frequently subjected to extreme uneasiness, but the tone of the mental faculties, and the capacity for exertion and attention are often affected by the state of the atmosphere.

I. Source of Air.—This cannot be too particularly examined. Many of the public buildings in this country are supplied with air from the lowest levels, principally with the view of facilitating the movement of the air through the flues. Hence at night, in clear weather especially, when the cold produced by radiation from the ground is great, and more or less at all times, cold air is supplied from the surface of the ground, or the public streets, loaded with the offensive emanations which they evolve, and which become much more disagreeable when subjected to the action of heat in a warming apparatus. By taking air from the highest attainable point, avoiding merely the immediate vicinity of chimneys, and any ingress of air at the same level, a much purer atmosphere is secured; and it may be conducted downwards to any required depth with a flue. In extensive public buildings situated in localities noted for the inferiority of their atmosphere, the erection of air towers to draw down a comparatively wholesome atmosphere from a height of two or three hundred feet, would be an object of great importance. In large towns, such as London and Manchester, where local impurities abound, and particularly when fog and frost are observed at the same time, special means may be adopted for removing those that are most offensive. Filter beds may be constructed for air on the same principle as for water; but few of the more simple arrangements of this kind that have been sustained for any length of time, have been found more desirable than filtration through any porous texture to exclude suspended blacks (soot), and in some cases also washing with water (particularly lime water), to condense sulphurous acid and other gases.

II. Amount of Air necessary for Ventilation.—Few subjects present a greater diversity of practice than this. From two to four cubic feet per minute for each person have usually been considered a large supply, but this is far beyond the amount usually allowed. A very slight examination will however show that even this amount is too small; for if the process of respiration be accurately examined, it will be observed that a cubic foot of air or more is involved or mixed and contaminated with the air discharged from the lungs at each expiration, independently of that affected by the skin. Such a supply, therefore, is at least desirable, were the air always at a mild and genial temperature. According to Dr D. B. Reid's experiments, where the effects of variable quantities of air were tried upon numbers included in an experimental apartment, not less than ten cubic feet of air per minute should always be allowed when it is at an agreeable temperature; and to sustain the atmosphere in all its freshness and purity, even a much larger quantity is at times desirable. In the present Houses of Parliament, from 36,000 to 50,000 cubic feet per minute have occasionally been given in warm weather to one apartment alone, or about 60 feet per minute to each individual in a crowded house. This question, however, of the amount of air necessary for ventilation, taking the deterioration produced by the human frame alone into account, is exceedingly complicated, and is influenced by a vast variety of circumstances, of which the following are the most important. In the preceding and following remarks, a temperature of 65° may be considered as the average most generally desired when there is a steady but gentle movement in the air. It is not so much the amount of supply with which life can be sustained, which is here investigated, as that which it may be desirable to afford, so as to maintain the system in its highest vigour and perfection.

1. *The purity of the air supplied.*—In general, the less pure the air, the greater the amount necessary for ventilation, especially if it be loaded with moisture, and charged with offensive exhalations from the lungs and skin. But cases do occur, when an atmosphere is so largely charged with poisonous effluviæ, that it becomes an object to use as little as possible to avoid this source of contamination, if it be not removed by special arrangements.

2. *The temperature.*—This is much the most important circumstance affecting the supply necessary for ventilation. When the air is very cold, and the moisture of the breath is condensed in hoar-frost as fast as it escapes from the lungs, a proportion of air, extremely small compared with the usual desirable allowance, will be sufficient for ventilation. Air, under ordinary circumstances, is below the temperature of the body in most parts of the globe. It therefore acts as a cooling power. But the higher its temperature, and the more nearly it approaches that of the body, the larger is the quantity required to produce an equivalent cooling power. Further, in warm weather the air is charged with more moisture than in the cold season, while the body is at the same time more exhalent of moisture. These and other circumstances tend to render the supply of air, desirable in warm weather, far greater than the mere arithmetical increase in the temperature would at first sight appear to indicate. But here we must advert to the popular error that the temperature, as indicated by the thermometer, is a proper guide to the quality of air, in respect to the warmth that may be most agreeable. The temperature, as a moment's reflection will show, is no indication, unless the velocity of movement and chemical qualities of the air, especially in reference to moisture, be also taken into consideration. A small quantity of air stagnant, and at 32°, may not cool the body more than a larger supply at 40°, 50°, 60°, 80°, or 90°, and, indeed, at any temperature below that of the living system. A large quantity of air not so cold may be made to produce the same amount of cooling effect as a less quantity of the colder air. It is equally obvious that a large quantity of air charged with much moisture, but not saturated, may produce the same amount of evaporation from the system as a less quantity of air containing little moisture associated with it.

3. *Idiosyncracy.*—A very wide range of experiments has shewn that the constitutional peculiarities of different individuals vary as much in respect to the amount of air desired, and the temperature at which it is preferred, as in respect to food or drink. In the houses of parliament, no temperature below 52°, or above 76°, has been demanded for several years. It is often very difficult to determine, however, how much is due to absolute peculiarity of constitution, and what is dependent on the circumstances of the moment, more especially, the state of occupation or excitement, the time that has elapsed since any refreshment was taken, and the nature and quality of the repast, the clothing in use, the previous exposure, the temperature, moisture, and other circumstances affecting the quality of the air. The brilliancy of the illumination also affects the supply of air required by some constitutions.

The force of habit is nowhere exemplified in a more marked manner, than in the amount of contamination which different individuals can bear. Some miners pass habitually much of their time in air in which a candle does not burn, though a lamp may be maintained in combustion in the same air.

Moisture in the air.—Air, in winter, usually requires the addition of moisture when introduced into any apartment and warmed, as at this season it has deposited a large proportion of the moisture associated with it in summer. Were it warmed by the approach of summer, it would, in this country, gain moisture from the surface of the earth or the ocean, and thus acquire more of the pleasing and agreeable qualities which a summer atmosphere presents; but, if warmed and introduced into any apartment without the previous addition of moisture, then, having had its power of action upon moisture increased without receiving a corresponding supply, it absorbs moisture with extreme rapidity from the surface of the body and the lungs, and, taking away an undue proportion, produces a harsh and disagreeable impression. The injection of steam into the air, or the evaporation of water from shallow metallic pans, placed over the heating apparatus, removes the defect.

On the other hand, moisture is frequently communicated to the air with the view of cooling it, by the reduction of temperature attending evaporation.

In some climates, again, a redundancy of moisture forms one of the greatest sources of oppression to the European constitution, and is regarded as one of the most powerful causes in developing the activity of miasmatous influence.

The influence of different degrees of moisture in the air is as various upon different constitutions as that of different temperatures. Further, some individuals exhale moisture almost solely by the lungs, while, in others, the skin is equally active. According to the relative conditions of the living system, the air, in reference to moisture, may either exhale, or absorb moisture from it.

I. Equalization.—Air entering by doors and windows, and rushing in a well-defined stream, so as to produce local currents, may be exceedingly offensive; while, if divided into innumerable streams, by causing it to pass through a porous texture, having the most extensive possible surface, it may escape so insensibly as not to be perceived. Air ought always to be admitted in this manner, or at such a distance from those upon whom it is to act, that its movement may be greatly moderated before it reaches the person. Wherever a proper supply of air is admitted, this equalization of movement is essential, more particularly in crowded apartments; and the greater degree to which it is carried, the larger is the quantity of air which the system can bear. Nothing is more common than to see apartments ventilated effectually, so far as may be necessary for removing the foul air; but this very ventilation induces a most offensive series of chilling draughts, if means be withheld for warming the larger supply now rendered necessary, and for introducing an effective equalization. In rooms for invalids, this subject becomes of great consequence, especially in diseases of the chest. And, generally speaking, to a great number of constitutions, unequal currents are more dangerous and offensive than an oppressive atmosphere.

V. Nature of Heating Power.—Few circumstances require more care and attention in connection with ventilation, than the nature of the heating power employed. The open fire, so much prized in this country from its lively and cheerful appearance, exerts also an agreeable effect upon the animal system, by the light radiated along with the heat which it evolves, and the movement of air which it sustains, as it draws off the air and ventilates the apartment in which it is placed; but, in point of economy of fuel, or facility of regulation, so as to maintain an equal temperature, it is perhaps the least desirable of all kinds of heating apparatus. The great beauty, therefore, which its appearance presents, the absolute purity of the heat which it conveys by radiation, and the extreme facility of access which it affords, so important for a variety of different purposes, ought to be contrasted with the attendance which it requires, the dust and ashes which it leaves, and the tendency, when neglected, to produce back-smoke, if the circulation be not maintained in proper force. In connection with ventilation, the following points require especial attention in the construction of the common fire-place. 1. It should be provided with an independent supply of air entering in its immediate vicinity, to be employed when heat is required in any apartment without changing the air there, as in warming the apartment before it is occupied, or moderating offensive currents near the fire-place. 2. An open fire-place, unless the air enters from the ceiling, often produces little or no ventilation above the level of the chimney-piece, and, even then, it does not afford the best and purest atmosphere. 3. The air above may be comparatively stagnant, and offensive in the extreme, from lamps and the products of respiration, while a fresh current moves along the floor to the fire-place.

Of other arrangements for heating apartments, the mild hot-water apparatus, when the water is always under a boiling temperature, affords the most perfect and equal diffusion, when properly arranged; a point of great importance in producing equality of ventilation. Stoves of low combustion, presenting an extensive surface at a moderate temperature, varying from 100° to 200°, according to their size, as the Russian, Prussian, and Swedish porcelain stoves, or Dr Arnott's stove, come next in order. Those varieties should be preferred which are provided with chimneys, both for the ingress and egress of air, having no communication with the apartment in which they are placed, otherwise, when worked most economically, they are all liable, occasionally, to evole carbonic acid, if they are not adjusted to the smoke chimney by persons who thoroughly understand their operation. Stoves and other apparatus, where the iron is heated to a high temperature, may be in many cases more economical than the preceding; but from the manner in which they affect the air, they are not so conducive to health, and greatly impede all regularity of ventilation, the hot air from them ascending rapidly to the ceiling, while a cold atmosphere, almost unaltered, is often left below.

In public assemblies, subject to great and sudden fluctuation of attendance, hot and cold air chambers are provided, from which any supply of warm or cold air may be obtained; and a mixing chamber, for mingling the various proportions that may be supplied, must also be constructed.

V. Source of Movement.—An alteration of specific gravity in the air, dependent on an alteration of temperature, produced by expired air and the warmth of the body, is the great, the more natural, and the most economical source of movement under all ordinary circumstances. When the openings for ingress and egress are arranged on the best footing, any ventilated apartment may be compared to a piece of apparatus in which the current of air, entering rapidly by a narrow channel, expands with the greatest possible diffusion into a slow moving stream, occupying the entire area of the place to be ventilated, and gathering together again in a smaller channel, by which it escapes, where the velocity of movement increases as the area diminishes. In ordinary apartments, where nothing more can be afforded, two openings, at different levels, will always give much relief; the one usually admitting cold, and the other, which should be as high as possible, discharging hot and foul air.

A movement in the air may be induced by mechanical means, more especially by pumps and fanners, or the impetus communicated to it by high-pressure steam. All

Ventilation.

these means may be seen advantageously employed where peculiar facilities are presented, as in manufactories.

The moving power of air itself is constantly taken advantage of, both for forcing and exhausting air. The windsail and the cowl are familiar illustrations where this power is resorted to; but the continuity of its action cannot be depended on, and it is perpetually varying in intensity. A large shaft or chimney, with a good fire, is more generally employed at present than mechanical means, though both may occasionally be introduced in the same place with advantage. In ships, Captain Warrington has proposed the introduction of a fanner; and a number of experiments was made on board the Benbow a few years ago by Dr Reid, who proposed the use of the same instrument, but who did not consider that it would attain all the purposes desired, unless conjoined with a system of diffusion and equalization, which has been partially introduced in the steam boats Albert, Wilberforce, and Soudan, constructed for the African expedition. There, arrangements have also been proposed for purifying the air, as the expedition traverses the most unwholesome districts.

VI. Ingress and Egress of Air.—Doors and windows, the only sources for the ingress of air in ordinary apartments, should be avoided as a means of introducing air in all new buildings, and independent apertures and flues provided, entirely under the control of valves, by whose action the amount of ingress can be regulated with precision. Further, in every apartment foul air should be led from the greatest altitude by similar independent flues. The ordinary construction often interferes seriously with ventilation, foul air descending sometimes in one and escaping in another. An alteration in the structure of houses, introducing one principal chimney, in which the flues from all the apartments ultimately join, would be a great improvement in this respect; and even for whole streets and districts one large shaft would be sufficient. To any who studies attentively the movement of currents of air, numerous other changes will present themselves as being equally desirable in the habitations of the rich and of the poor. In public buildings, the foul air, from hundreds of apartments, will be removed by a single shaft.

The reader who is anxious to extend his knowledge of this subject, will find much information in the Parliamentary Reports, particularly on the Ventilating and Acoustic arrangements of the present House of Commons, on the Ventilation of Mines, in many of the Reports on Education and on Manufactures, in which the health of the children has more particularly engaged attention; in the Reports on Improving the Health of Large Towns, and in some Statistical Reports on the Health of the Army and Navy. Tredgold on Warming and Ventilating, is a work of great value, and the different memoirs and treatises of D'Arcet, present numerous important details. In Dr Arnott's work on Warming and Ventilating, a full description of his stove is given; and in Hood's, and also Richardson's treatise on the same subjects, the different varieties of hot water apparatus are explained. In Dr Reid's Chemistry of the Atmosphere, and Illustrations of Warming and Ventilating, the result of numerous experiments is given on the ventilation of public buildings and private dwelling-houses, and the ventilation of ships, manufactories, &c.

The laws of the communication of heat, the electrical condition of the atmosphere, the diffusion of gases, the fluctuations of the barometer, the indications of the hygrometer; the *plenum movement*, when the pressure of the air within, from mechanical means, exceeds that without the apartment ventilated; the *vacuum movement*, when the reverse is induced; the *downward* and *lateral* current, especially the former, which is so important in protecting works of art exposed in public assemblies; the precautions necessary where it may be introduced, the influence of different varieties of clothing, of medicated atmospheres, of moist and dry air baths at different temperatures, and of fumigation, are all objects of inquiry that bear practically on ventilation. The peculiar arrangements in various mines, hospitals, and manufactories, especially where offensive vapours are condensed or destroyed, likewise afford many valuable illustrations of its practice. (D. G.)

VENTILATOR, a machine by which the noxious air of any close place may be discharged, and replaced by fresh.

VENTIVALUM, a town in the Southern Carnatic, forty miles west-north-west from Pondicherry. Long. 79. 25. E. Lat. 12. 10. N.

VENTRICLE properly denotes any little cavity; but is more particularly used by physicians and anatomists for the stomach and certain cavities of the heart and brain.

VENTRILOQUISM, an art by which some individuals can so modify their voice, as to make it appear to proceed from any distance, and in any direction.

VENUS, in Pagan worship, the goddess of love and beauty. Cicero mentions other two deities of this name, Venus, styled *Urania* and *Cœlestis*, and the *Venus Pandemos* or *Popularis*, the wife of Vulcan, and the goddess of wanton and effeminate love. To the first the Pagans ascribed no attributes but such as were agreeable to the strictest chastity and virtue; and of this deity they admitted no corporeal resemblance, she being only represented by the form of a globe, ending conically. Her sacrifices were termed *nephalia*, on account of their sobriety. To her honey and wine were offered, and no animal except the heifer; and on her altars the wood of figs, vines, or mulberries, was not suffered to be burnt. The Romans dedicated a temple to this goddess, to whom they gave the name of *Verticordia*; because she turned the hearts of lewd women, and inspired them with modesty and virtue.

But the most famous of these goddesses is the wife of Vulcan; who is represented as springing from the froth of the sea. As soon as she was formed, she was laid in a beautiful shell embellished with pearl, and wafted by gentle zephyrs to the isle of Cythera, whence she sailed to Cyprus. At her landing, flowers rose beneath her feet; she was received by the Hours, who braided her hair with golden fillets; and then wafted her to heaven, where her charms appeared so attractive, that most of the gods desired her in marriage; but Vulcan, by the advice of Jupiter, gained possession by putting poppies into her nectar. As Venus was the goddess of love and pleasure, the poets have been lavish in the description of her beauties; and the painters and statuaries have endeavoured to give her the most lovely form. Sometimes she is represented clothed in purple, glittering with gems, her head crowned with roses, and drawn in an ivory car by swans, doves, or sparrows; at others she stands attended by the Graces; but in all positions, her son Cupid is her inseparable companion. She was honoured as the mother of Hymenæus, Cupid, Æneas, and the Graces, and was passionately fond of Adonis and Anchises. This goddess was principally worshipped at Paphos in Cyprus; and the sacrifices offered to her were white goats and swine, with libations of wine, milk, and honey. Her victims were crowned with flowers, or wreaths of myrtle.

VERA CRUZ, one of the nineteen states which compose the republic of Mexico: also the capital city of that state. See Mexico.

VERAMALLY, a town in the Southern Carnatic, twenty-three miles south-west from Trinchinopoly. Long. 78. 35. E. Lat. 10. 26. N.

VERCELLI, a province of the kingdom of Sardinia, in the principality of Piedmont. A part of it is mountainous, but the other portions are fertile, especially in the valleys, where much rice is produced. It contains three cities, and seventy-three towns and villages, with 99,600 inhabitants. The capital is a city of the same name. It is

Vermilion, Vermin.

situ ed on the canal of Santhia, not far from the river Les . It is the seat of a bishop, with a cathedral of modern styl ; and contains nine parish churches, ten monasteries, and even nunneries, some of the first remarkable for their arch ecture. There is also an episcopal seminary, and a gra nar school. It contains a population of 16,500 persons who are chiefly occupied in raising silk, and in cultivati g rice and other grain. Among the inhabitants are ma noble families, who, though poor, still retain magnificen palaces. Lat. 46. 20. Long. 7. 43. E.

V RCHAIRALSK, a small town of Asiatic Russia, in the rovince of Onfa on the Oural, 120 miles S.E. of Onfa.

V RCHATURIA, a town on the western frontier of Sib ia, where is established the custom-house of Siberia, whi levies a duty of 10 per cent. on all goods passing thr gh it. This town is situated near extensive mines, and con ins 450 houses, four churches, and two convents. It is 120 hiles north of Catherinenburg. Long. 60. 14. E. Lat. 53. 5. N.

V RCHOLENSK, a small town of Asiatic Russia, in the overnment of Irkoutsk, on the Lena, 120 miles north of I outsk.

V RD, CAPE, a promontory on the west coast of Afr a, forty miles north-west of the mouth of the river Ga bia, in 14° 45′ north lat., and 14° 40′ west long. The Ca Verd islands are situate about 400 miles west of the Ca ; they consist of ten islands beside islets and rocks, an elong to Portugal. The principal is San Jago, the bar n and melancholy appearance of which is in unison wit the wretchedness of the inhabitants. The island of Ma produces cattle and cotton; the island of Fuego (or Fi), so called from its active volcano, is abundant in fru s. Brava, or St. John's, produces excellent wine and sal etre. These four islands form a chain, running from eas to west. The island Boa-Vista, which is fertile in cotton nd indigo, forms, with the island Sel, or Do Sal, a line no h and south. The four remaining islands form part of a c in in the direction of south-east to north-west, and suc eed each other in the following order: St. Nicholas, on of the largest and best governed of the archipelago; Sa a Lucia, high and wooded, with only brackish water; Sa Vincente, wooded and abounding in tortoises; and San A onia, the mountains of which are said to equal the peak of eneriffe in height. All these islands are subject to destr ctive droughts; but their natural produce might render th n of considerable value under an intelligent government. T ir population is reckoned at about 42,000.

ERDUN, a city of France, the capital of the arrondi ement of the same name, in the department of the Meuse, ar standing on that river. It is strongly fortified, and has a ost powerful citadel, and is considered one of the most in ortant defences on that side of the kingdom. In 1836 it co ained 9978 inhabitants, exclusive of the military. It ha woollen manufactories, and tanneries, and is celebrated fo ts liqueurs. Lat. 40. 9. Long. 5. 12. E.

EREJA, a city of Russia, the capital of a circle of the sa e name, in the government of Moscow, 513 miles from P ersburg. It stands on the river Protwa, whose water ca be used to fill the trenches that surround the walls. The to n has considerable trade in corn, hemp, flax, honey, wax, ta ow, and wool. It contains 760 houses, 6450 inhabita s, of whom 930 are registered as merchants.

ERGE, in *Law*, signifies the compass of the king's c rt, which bounds the jurisdiction of the lord steward of t household. It is supposed to have been twelve miles round.

ERGERS, officers of the courts of queen's bench and c mon pleas, whose business it is to carry white wands fo the judges. There are also vergers of cathedrals, who ca y a rod tipped with silver before the bishop, dean, &c.

ERMICELLI, a composition of flour, cheese, yolks of e s, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes.

VERMILION, a bright and beautiful red colour composed of quicksilver and sulphur, in great esteem among the ancients, under the name of *minium*.

VERMIN is a general term, denoting those animals which are either directly or indirectly injurious to mankind, the inferior animals, or the fruits of the earth; as fleas, caterpillars, flies, worms, &c.

As we propose in this article to point out the means of destroying some of those animals, we shall employ the term vermin in a more extended sense, including also under it, mice, rats, moles, &c.

Rats and Mice.—Various methods have been proposed for the destruction of these vermin. The following preparation has been recommended as very effectual. Take of the seeds of stavesacre (*delphinium staphisagria*), or of lousewort (*pedicularis palustris*), powdered, more or less as the occasion requires, one part; of oatmeal, three parts; mix them well, and make them up into a paste with honey. Lay pieces of this paste in the holes, and on the places where mice and rats frequent; and it will effectually kill or rid the places of those vermin by their eating it.

The Society for Encouraging Arts proposed a premium of L.50 for a preparation capable of alluring or fascinating rats, so that they might be taken alive. In consequence of this, a great number of new traps, &c. were invented, and the following methods of alluring the rats to a certain place were divulged. One of the methods which is most easily and efficaciously practised, is the trailing of some pieces of their most favourite food, which should be of the kind that has the strongest scent, such as toasted cheese or boiled red herrings, from the holes or entrances of the closet to their recesses in every part of the house or contiguous building. At the extremities, and at different parts of the course of this trailed track, small quantities of meal, or any other kind of their food, should be laid, to bring the greater number into the tracks, and to encourage them to pursue it to the place where they are intended to be taken. At that place, when time admits of it, a more plentiful repast is laid for them, and the trailing is repeated for two or three nights. Besides this trailing and way-baiting, some of the most expert of the rat-catchers have a shorter, and perhaps more effectual method of bringing them together; which is the calling them, by making such a whistling noise as resembles their own call; and by this means, with the assistance of the way-baits, they bring them out of their holes, and lead them to the repast previously prepared for them at the places designed for taking them. But this is much more difficult to be practised than the art of trailing; for the learning of the exact notes or cries of any kind of beasts or birds, so as to deceive them, is a peculiar talent which is attained only by few.

In practising either of these methods of trailing or calling, great caution must be used by the operator to suppress and prevent the scent of his feet and body from being perceived; which is done by overpowering that scent by others of a stronger nature. In order to do this, the feet are to be covered with cloths rubbed over with assafœtida, or other strong smelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its high price, though it has a very alluring as well as disgusting effect. If this caution of avoiding the scent of the operator's feet, near the track, and in the place where the rats are proposed to be collected, be not properly observed, it will very much obstruct the success of the attempt to take them; for they are very shy of coming where the scent of human feet lies very fresh, as it intimates to their sagacious instinct the presence of human creatures, whom they naturally dread. To the above-mentioned means of alluring by trailing, way-baiting, and calling, is added another of very material efficacy, which is the use of oil of rhodium.

Like the *marum Syriacum* and *valerian* in the case of cats, it has a very extraordinary fascinating power on these animals. This oil, as it is extremely dear, is therefore sparingly used. It is exalted in a small quantity in the place, and at the entrance of it, where the rats are intended to be taken, particularly at the time when they are to be last brought together, in order to their destruction: and it is used also by smearing it on the surface of some of the implements used in taking by the method described below. Its effect in removing their caution and dread, by the delight which they appear to have in it, is very extraordinary. It is likewise usual for the operator to disguise his figure as well as scent. This is done by putting on a sort of gown or cloak, of one colour, that hides the natural form, and makes him appear like a post, or some such inanimate thing, which habit must likewise be scented as above, to overpower the smell of his person; and besides this, he is to avoid all motion till he has secured his point of having the rats in his power.

When the rats are thus enticed and collected, where time is afforded, and the whole in any house and out-buildings are to be cleared away, they are suffered to regale on what they most like, which is ready prepared for them, and then to go away quietly for two or three nights; by which means those that are not allured the first night, are brought afterwards, either by their fellows, or the effects of the trailing, &c., and will not fail to come duly again, if they are not disturbed or molested. Many of the rat-catchers make shorter work, and content themselves with what can be brought together in one night; but this is never effectual, unless where the building is small and entire, and the rats but few in number.

The means of taking them when brought together are various. Some entice them into a very large bag, the mouth of which is sufficiently capacious to cover nearly the whole floor of the place where they are collected. This is done by smearing some vessel, placed in the middle of the bag, with oil of rhodium, and laying in the bag baits of food. The bag, which before lay flat on the ground with the mouth spread open, is to be suddenly closed when the rats are all in. Others drive or frighten them, by slight noises or motions, into a bag of a long form, the mouth of which, after all the rats are come in, is drawn up to the opening of the place by which they entered, all other ways of retreat being secured. Others, again, intoxicate or poison them, by mixing with the repast prepared for them, the *coculus Indicus*, or the *nux vomica*. They direct four ounces of *coculus Indicus*, with twelve ounces of oatmeal, and two ounces of treacle or honey, made into a moist paste with strong beer; but if the *nux vomica* be used, a much less proportion will serve than is here given of the *coculus*. Any similar composition of these drugs, with that kind of food which rats are most fond of, and which has a strong flavour to hide that of the drugs, will equally answer the end. If indeed *coculus Indicus* be well powdered, and infused in strong beer for some time, at least half the quantity here directed will serve as well as the quantity before mentioned. When the rats appear to be thoroughly intoxicated with the coculus, or sick with the nux vomica, they may be taken with the hand and put into a bag or cage, the door of the place being first shut, lest those which have strength remaining should make their escape.

In destroying rats, advantage may be taken of that remarkable degree of instinct which they possess of deserting one place, where they find themselves disturbed or harassed, and retiring to new haunts. It is well known, that after one or two rats are poisoned, or taken in traps, or wounded or otherwise injured, and afterwards permitted to escape, the whole colony immediately disappears. The practice, however, of destroying by poison rats that frequent dwelling-houses, should be as much as possible avoided; for they retire to places behind the wainscot, &c. from which, after death, their putrid bodies, emitting a most offensive smell, cannot be removed. But it is far less difficult than is generally imagined to secure the different apartments of a dwelling-house, and even the cellars, from the inroads of rats and mice, and thus to prevent their unwelcome visits, by shutting up the passages through which they enter. Stone and lime, when they can be applied, are effectual; but common plaster, by introducing pieces of broken pottery ware or glass along with it, will also answer the purpose; and even a piece of cork, with a pin or two stuck through it to prevent them from eating it away, is a complete barrier to mice entering through a hole in wood, and may even prevent the entrance of rats. We have seen this method of shutting up the holes, as soon as they were opened by the industry of the enemy, steadily pursued for some time, attended with the fullest success, even in an old house of considerable extent, and finished from top to bottom with wood, some of which was much decayed.

For the sake of food, rats and mice often frequent gardens, fields, and woods, in the summer season; but, on the approach of winter, they return to their former haunts in the habitations of man; and accordingly it is observed that houses which are free from those vermin during the summer, swarm with them about the end of autumn. Attention to this circumstance in the habits of these animals, may be the means of securing us from their visits and depredations; for if, at the time alluded to, every hole and cranny through which mouse or rat can enter, be shut up, and carefully kept close and secure, the perseverance of the foe is exhausted and overcome by repeated and constant resistance, and thus he is forced to abandon the unequal contest, and to retire to other haunts where his motions are less interrupted.

Various other methods have been proposed for the destruction of rats; and although we have thrown out a hint against the use of arsenic for this purpose in dwelling-houses, yet where it can be employed with perfect safety, and without risk of the nuisance alluded to, as in cellars and outhouses, it is undoubtedly one of the most effectual to which we can have recourse.

Suffocating these vermin by means of the fumes of sulphur, as on board of ships, in granaries, and other buildings, which can be shut up, is sometimes successfully practised. Rats and other vermin have also been effectually destroyed by burning wood in close apartments, thus producing fixed air or carbonic acid gas, by which they are suffocated.

Moles.[1]—The mole is found in all parts of Great Britain. It is seldom or never seen above the surface of the ground, except when forced out of its subterraneous abode by excessive drought and heat, by inundations, or by very hard frost. In size it is a little larger than the dormouse, and smaller than the common rat, measuring from five to six inches in length, exclusive of the tail. The male is considerably larger than the female. The body is completely covered with very fine glossy black hair or fur, softer and finer than silk, or the fur of the beaver, inclining to a brownish hue on the abdomen.[2] Its nose is long, and resembles that of the hog; its eyes are very quick and perceptible when the animal is alive. Instead of external ears, it s openings protected by the fur, which are admirably fitt l for their purpose, as the hearing of few animals is mo acute. Its neck is very short, and its body is thick, ro d, and muscular, terminated by a tail about an inch lon The fore-legs have more the appearance of hands gro ing out of the body, turned outwards and backwards, lik he hands of a man when swimming. These legs are ver strong, and are each furnished with five claws. The hin legs are longer and weaker than the fore ones, being onl used in progressive motions; whereas the others are con antly employed in digging and boring the ground, or in s raping and throwing back the earth when loosened; for whi the mole is excavating, it is always obliged to draw the osened earth backwards, and to lift or shove it above the urface of the ground in the same way. Its teeth are bea ifully white, and consist of forty-four in all, viz. six upp r and eight under incisors, two upper and two under can es, and seven molars on each side above, and six on eac side below. Its food consists almost entirely of earthwo s and a few insects.

---

[1] The observations on the structure and habits of the mole, and on the mode of trapping it, have been communicated by Mr. Thomas Yeadell of Preston, for many years practically engaged in the art of mole-catching.

[2] Whole families of fine cream-coloured moles have sometimes been taken; and Mr Yeadell once took a whole litter of piebalds, but he never took or saw a perfectly white one.

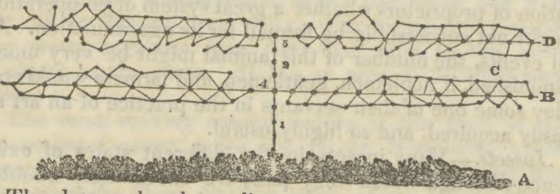
e male and female go together about the end of March or eginning of April, and most of them produce their you g in the beginning of June, a few so early as the last wee in May.[1] The female brings forth her young only onc a-year, the number varying from one to nine at a birt and five or six being the average number. She car s her young about nine weeks, that is, from the last wee in March or the first in April, till the last week in Ma or beginning of June. When the season arrives for the male and female going together, if their domiciles are not onnected by old workings, the solitary mole will leave his ace of abode in the night, and travel a considerable dist nce above ground to meet with a companion.[2]

e season for trapping moles in Scotland commences on e 20th of August, and ends on the 31st of May in eac year, or occasionally a week or two later if the winter be severe one.

out forty years ago, when steps were taken to clear the moles from the estates of his grace Henry duke of Bu euch in Scotland, a man was appointed to each five tho and or six thousand acres of land, for two or three of the st years of a twenty years' lease; and so much success atte led the plan, that two men were sufficient to keep fifty housand Scotish acres of land pretty clear of moles dur g the remainder of the lease. And had it not been that here were several intervening patches of land, where the oles were not trapped at all, and where their propagat n was kept up, one man would probably have sufficed for e purpose.

T e most common way of taking moles, is by traps set in t ir walks or runs; and the best for this purpose are the woo n ones made by the bobbin turners in the neighbourhoo of Kendal and elsewhere, and sold at about twopence eac Sixty of these traps, with as much mole-twine as may be bought for eighteenpence, a few sticks, a small bod n, and a mole-spade, equip the mole-catcher, and will serv him for a year without any additional outlay. With thes materials, in good ground, where the moles have not before been disturbed, he will capture three hundred dozens the first season. Before commencing operations, the traps should be steeped in water, and covered in the ground for a day or two, to remove any peculiar smell which may belong to them.

In the subterraneous runs of the mole, as among the streets of towns and villages, there are certain walks more frequented than others, and hence entitled to the name of thoroughfares.



The dots in the above diagram represent the mole-hills, and the lines the walks or streets communicating between them, which serve the double purpose of a dwelling and a trap for worms, upon which the mole feeds. It is probable that all these streets, or at all events a large proportion of them, are traversed every twenty-four hours, more especially when food is scarce. It is also obvious that certain parts of these walks must be more frequently passed than others.

A may be supposed to be a hedge near which the mole will spend much of its time in wet, cold, or stormy weather; B and D are two ridges adjoining to the hedge, where it is much engaged in fine weather; and C the furrow between those ridges. Let fig. 1 represent the walk conducting from the hedge to the first ridge, and fig. 2 a continuation of the same walk between the first and second ridges. Figs. 3 and 4 are mainwalks on the ridges. Nos. 1 and 2 are the walks that will be most used, and therefore are the places where the mole-catcher would place his traps. Nos. 3 and 4 are the next best, in consequence of there being only a single road or passage in each place, and not, as to the right and left of them, a variety of byeways. In many cases the inexperienced may be unable to determine which is a main run, in consequence of the ground being apparently all worked up together. In such a case he should endeavour to find a walk in a hedge bottom, or in crossing the ditch to the hedge, or where the mole goes to water, or in the crossing of a gapstead or gateway, or in a footpath, or furrow, or sheepwalk, or along the side of a drain. In such places as these, the ground is generally pretty solid, and it may be assumed as a general rule, that the mole never likes to make a great number of walks where the ground is hard, or where it is frequently trodden on. When the mole-catcher has surveyed the ground, and made up his mind where to place his trap, as at Nos. 1, 2, 3, and 4, he may strike his spade into the ground in a right line, between the hillocks, and if he finds the ground hollow, he has discovered the walk, and he may there make a hole to set his trap in. Care must be taken not to make this hole too large, and it ought to be about a quarter of an inch lower than the bottom of the walk, so that the mole may have a gentle descent into it. The earth ought also to be well filled in upon all sides, so as to exclude the light, and at the same time not to interrupt the mole in its passage; for upon discovering any interruption, it will be apt to make a new road by the side of it, and after having its suspicion excited, it will be very difficult to take it afterwards.[1]

---

[1] r. Yeadell comes to this conclusion from his observation of the state of the female about this time, and from frequently having taken the ole litter of young in the nest, which is easily found, from its being made in the centre of an unusually large hillock. Although the le is here stated to breed only once a-year, it is the recorded belief of some observers, that two broods are annually produced, one spring or early in summer, and another in autumn. The more usual and characteristic period, however, we believe to be the spri and this accords with the practical observations of continental naturalists on the subject.

[2] is is a circumstance which Mr. Yeadell conceives to be proved in various ways; first, by his frequently having found the workings enti y abandoned in particular places in the months of March and April; secondly, by finding unusually large numbers of moles together at t time; and, thirdly, by incidental circumstances, such as taking a mole which had lost his tail, or had been deprived of a hind leg. In 9 Mr. Yeadell took a mole without a tail, and the following year he took one wanting a hind leg, both of which had been twisted off, in tr s of his own, at the distance of a mile or more from the place where they were at last taken. The most frequent cause of the mole char g its ground arises from inundations. When the rivers rise rapidly and cover his workings, he is obliged to abandon his subterrane bode, and swim for his life, which he can do with the buoyancy of a water-rat.

The destruction occasioned by the mole is by no means generally understood. It might be worthy of the consideration of proprietors whether a great system of co-operation might not successfully be formed for its extermination. At all events, the number of this animal might be very much diminished, if noblemen, gentlemen, and farmers would employ some one of their servants in the practice of an art so easily acquired, and so highly useful.

Insects.—Many insects, in the different states of existence through which they pass, are exceedingly troublesome and destructive. Sometimes they spread their devastations in the state of *larva* or *grub*, and sometimes in that of perfect insect.

Of the coleopterous insects, the grub of the cock-chafer, which is a brownish or chesnut-coloured beetle, commits the greatest ravages. This beetle appears during great part of the summer, the most plentiful in May or June, and hence is called the *May bug*. It flies only in the evening, and lodges during the day under the leaves of trees, which it devours, and is sometimes in such numbers, as to defoliate whole woods. The beetle deposits its eggs in the earth, and from these are hatched white or bluish grubs, that feed on the roots of grass, corn, and other vegetables, during the whole summer. In the winter they lie deep in the earth; but in the spring, as vegetation advances, they rise to the surface, and renew their work of destruction. In this state they continue for four, five, or six years, before they change to the chrysalis state, in which they remain till the month of May, when the perfect insect appears. As these insects require so many years to assume the perfect form, they only appear occasionally in sufficient numbers to be extensively destructive to the crops of grain, or vegetables in general. Their numbers, however, have often produced great alarm, and even excited the attention of governments to offer rewards for an effectual method of destroying them.

In the spring season, if the weather prove warm, when the land is ploughed up, these grubs are generally so near the surface as to be turned up with the plough; and being thus exposed, they are picked up and devoured by various birds, which, it is suggested, should not be disturbed or driven away in this salutary labour. When these grubs infest meadow land, it has been proposed to drown them in their holes by overflowing it; but it is supposed that this plan would not be successful, even where it is practicable, unless there is a bed of clay immediately under the soil, to retain the water for a sufficient length of time. A more efficacious way is recommended to prevent the increase of the grubs, by destroying the flies in May or June, before they have deposited their eggs. This may be done by shaking and beating the trees and hedges in the middle of the day; and, as this is a work which may be performed by children, it is a less difficult task than would at first sight be imagined. Domestic fowls are remarkably fond of these beetles, so that a double object is thus gained, the destruction of the beetles and the procuring of food for the poultry.

Some species of the dermestes, and also of the genus *ptinus*, are exceedingly destructive in the cabinets of naturalists, and also to furniture. Various methods have been recommended to stop their ravages. We believe the most effectual is spirit of turpentine, when it can be properly applied. A solution of corrosive sublimate is sometimes employed, but it should be recollected that it seldom fails in time to produce some chemical change on animal and vegetable matter. Objects of natural history, as birds, animals, &c., are sometimes exposed to the moderate heat of an oven, or before a fire, for several hours; but this method will also be attended with injurious effects, unless practised with great care. Insects which infest furniture have been destroyed by the application of oil, and allowing it to remain for a day or two, before the furniture is rubbed up. Japanned or varnished furniture may be secured from the effects of these insects, by re-coating it, when they are in the larva state, by which they are deprived of air. Railing, and other works out of doors, which are exposed to the weather, are sometimes eaten with insects, and particularly by some of the larvæ of the genus *curculio*. The wood thus attacked may be prevented from farther ravages, by a fresh coat of paint.

The earwig is a destructive insect in the flower, kitchen, and fruit garden. To prevent their depredations, it has been recommended to take them with the hand, when they come out during the night in search of food. They may be taken also by rolling up a piece of paper, and hanging it up on the plants which they infest; for in these places they take shelter through the day. Another method of destroying them has been mentioned, and that is to watch them towards morning with the view of discovering the haunt to which they resort during the day. This may perhaps be a melon frame, dunghill, or heap of rubbish; and the removing of it will destroy the greater number of those troublesome insects.

The small insect which commits such depredations among turnips, by eating the seedling leaves as soon as they appear, as frequently to destroy whole crops, is supposed to be a small black polished beetle, belonging to the genus *Altica*. It does not seem to be well ascertaine whether this small beetle, which is better known by th name of turnip-fly, commits its ravages in the larva or i the beetle state. It is said to prefer the leaves of th common radish to those of the turnip; and it is therefor recommended to sow radishes along with the turnips, to prevent the destruction of the latter.

Of the insects belonging to the order hemiptera, ther are some which are exceedingly destructive. The cockroach, a native of the warmer parts of America and th West Indies, is a very troublesome, and a very voraciou insect. It has been introduced into this country, and particularly into the sea-port towns, in consequence of commercial intercourse. It comes out to feed in the night time, and eats of almost every thing that comes in its way Cockroaches are easily taken by the following metho Cover the outside of a deep glass or bason with paper; introduce some bits of bread or sugar into the bason or glass and set it in a place frequented by the cockroaches. The creep up by means of the paper on the outside, and dro i o the vessel; but in consequence of its smooth polished s face, they cannot effect their escape. In the same way c kets and beetles may be taken and destroyed. It is q te unnecessary to speak of the means of destroying the n riads of locusts which not unfrequently infest eastern c ntries, and particularly Egypt and Syria; for no means a likely to be devised, which promise to resist the effects o uch an host of foes, by whose ravages every green thing is consumed; but the insect itself becomes, among the p rer inhabitants of those countries, a partial substitute f the fruits of the earth which it has destroyed. The inse s are taken, and reduced to powder, and converted into a nd of meal.

---

[1] Sometimes, when Mr. Yeadell has met with a mole which had been rendered cunning from the string of a trap having broken, or fro its having been caught by the tail or by a hind leg, which it had twisted off, and escaped, he has successfully resorted to the various stra tagems. The first of these is to form a cake of softish earth about half an inch thick, to be plastered over both ends of the trap, so effectually to interrupt the passage. The mole, upon reaching this obstacle, immediately sets to work to remove it, and no sooner has dug its way through the earth, and against the trigger, than the trap strikes, and it is taken. When this stratagem failed, he wa accustomed to set a dead mole upright upon its hinder part, with its head standing up into the centre of the trap, so as to touch the trigger and whether from the combative propensity of the mole, or from its desire to relieve a companion, it rushes at the dead mole, displaces t trigger, and is taken. The last stratagem he never found to fail. In all cases, but more especially in those of a difficult natur care ought to be taken to have the trap and strings in perfect order, using a strong stick for a spring, so that the animal shall be firmly secure

he common or the bed-bug is a very troublesome and a ery common inmate in the crowded houses of large to ns. Its usual haunts are the crevices of wood, and particula y those pieces of furniture which are usually kept in the w mest corners of the apartment. Cleanliness will perh s be found the best preservative against the introducti and increase of these insects; but sometimes even the g atest care and attention are ineffectual in keeping h ses entirely free from them. When it can be convenie y done, they are completely destroyed by immersing th furniture in boiling water, or by baking it in an oven; a by filling up the crevices or holes which were their h nts, with glaziers' putty, their return and increase will th s be prevented. But a very effectual method of destroyin bugs, is to wash the places which they frequent with s it of turpentine, and then to fill up the holes as already m ntioned. It is a curious circumstance in the history of th se insects, that some persons entirely escape from their a cks, while to others they are exceedingly troublesome a distressing. It is said that lavender-water, sprinkled o r the bed-clothes, often prevents their approach.

he small moth which, in the caterpillar state, commits r ages on woollen cloths, furs, and other animal subs nces, that remain for any length of time in dark und urbed places, may be destroyed with the greatest cert ity and facility, by exposing the substances on which t y are suspected to make their depredations, to the vapour o spirit of turpentine, or brushing them with a brush dipp l into the same fluid. This should be done about the m nths of September or October; but their effects may be p vented by placing the cloths, furs, &c., which are likely t become their residence, in an airy situation, about the m nths of July and August.

he different kinds of lice are very numerous. Every a mal has its peculiar species, and even mankind are not f from this pest. It is often the consequence of indol ce and nastiness; and it is observed that the lice which i st any animal increase prodigiously when that animal b omes languid and sickly. We believe that the applicat n of spirits of turpentine, already so often recommended, w ld also be effectual in this case; but mercurial prepara ons afford a certain remedy against these insects. For t s purpose a very small quantity of what is called mercur ointment may be employed. At the same time it o ght to be recollected, that cleanliness is the best preserv ive.

It is perhaps more difficult for mankind to secure thems ves and their habitations from the visits of the common f . Cleanliness may however do much even in effecti this; and,' in particular, it appears to us that it would b extremely useful, frequently to rub up with a piece of c th the more inaccessible parts of furniture or apartments, o perhaps it would answer better to employ a small hard b ish. By the less accessible places, we mean the corners a l crevices of rooms and furniture where dust is apt to c lect, and especially the canvass part of a bed. We are p suaded that spirits of turpentine might also be found u eful for the destruction of these very troublesome insects.

The Scottish myrtle (*myrica gale*, Lin.) a plant very common in low and moist moorish places in this country, is said to be an excellent remedy, in consequence of its powerful aromatic odour, against the attacks of these animals. For this purpose, the plant is strewed about the apartment or bed which is infested with fleas.

Vermont.

VERMONT, one of the United States of America. It lies between the river Connecticut and the long tapering basin of Lake Champlain; stretching from 42° 44′ to 45° north lat., a distance of nearly 160 miles, and from 71° 30′ to 73° 20′ west long., with a breadth expanding pretty regularly from forty-five miles in the south to ninety in the north. It has an area of 10,200 square miles.

Mountains.

The most striking natural feature of this tract is the mountainous range called the Green Mountains, which traverse the state from north to south, and, passing into Massachusetts, there take the name of the Hoosic Mountains. In the centre of the state this ridge is divided into two, of which the one called the Height of Land runs north-east to Canada, and the other, taking a north-westerly direction, sinks down in the northern part of the state. The Green Mountains, from whose verdure this state derives its name, are from ten to fifteen miles wide, and are much intersected by valleys; they are watered by numerous springs and brooks, and are covered with evergreen trees and shrubs nearly to their summits. There are many good farms among the mountains, and much of the land upon them is suitable for grazing. The highest points are Mansfield Mountain, rising to 4280 feet; Camel's Rump, 4190 feet, both in the north-western ridge; and Killington Peak, further south, 3675 feet in height. Ascutney, a detached elevation near Windsor, rises to the height of 3320 feet above the level of the sea.

Rivers.

The Connecticut forms the eastern boundary of the state. Oniou river passes through Montpellier, the capital, into Lake Champlain at Burlington. Otter creek is a principal branch of Oniou river. Lamoile and Missique are considerable streams north of the Oniou. In the Green Mountains rise many smaller rivers, which at once beautify the country by the picturesque scenery of their banks, and promote its manufactures by the mills which they turn in their course. Those which run towards the east are tributaries to the Connecticut, and those whose course is towards the west discharge their waters into Lake Champlain.

Lakes.

Lake Champlain, between the west shore of this state and New York, is a beautiful sheet of water, 128 miles long, and from one to twenty wide. It discharges at its northern extremity by the river Sorel into the St. Lawrence, and contains upwards of sixty islands, of which Motte, and North and South Hero, are of considerable size. Besides the rivers which flow into it from the Green Mountains, it receives the Chazy, Sarauac, Sable, Bouquet, and Wood rivers, from New York, on the western shore. The Champlain canal connects it with Hudson river and the New York and Erie canal. Lying extremely convenient to facilitate the commerce of the state both with New York and Montreal, it is navigated by a number of steam-boats and lake vessels. Memphremagog is a considerable lake, twenty-five miles long and three broad, lying partly in Vermont and partly in Canada, receiving a number of streams from this state, and communicating by the St. Francis with the St. Lawrence.

Minerals.

The prevailing rocks belong to the stratified primary group, embracing mica and talcose slates, gneiss, primary limestone, argillite, &c. On the western border there is a narrow strip of transition limestone. These rocks afford good building materials, and marble is quarried and carried out of the state. The magnetic oxide of iron abounds at Somerset, and the brown hematite, associated with oxide of manganese, occurs at Bennington, Pittsford, and Manleton. Pyrites, or sulphuret of iron, is found in Strafford and Shrewsbury; and about three million pounds of copperas, of the value of 70,000 to 75,000 dollars, are made here annually.

Forests.

Vermont was originally covered with a dense forest, a large part of which still remains, although considerable encroachments have been made on it in clearing land for cultivation, and in felling trees for timber. The mountains produce hemlock, spruce, and fir; the lower grounds, various species of oak, pine, maple, elm, hickory, beech, birch, ash, buttonwood or sycamore, and lime or basswood, and the cedar grows in wet places. Ginseng, sarsaparilla, sassafras, snakeroot, lobelias, &c., are also among the products of the forest. Maple-sugar is made in large quantities for domestic use and exportation, and pot and pearl ashes, and lumber, are also exported.

Political divisions.

Vermont is divided into fourteen counties, which are subdivided into townships. There are no large towns in the state, but Vergennes has the name of a city.

Population in 1830.

Vermont is not a slave-holding state. The number of newspapers published in this state in 1839 was thirty-one.

The senate established in 1836 consists of thirty members, each county being entitled to at least one, and the rest apportioned according to population; and the House of Representatives is composed of one member from each town.

VERNIER SCALE, a scale excellently adapted for the graduation of mathematical instruments, thus called from its inventor Peter Vernier.

VERNON, a city of France, in the department of the Eure, and the arrondissement of Evreux. It stands in a fine valley situated on the banks of the Seine; and in 1836 it contained 710 houses, with 4485 inhabitants. They carry on considerable trade in corn and flour, and have some large tanneries. Near to it are some valuable stone quarries, which supply the builders of Havre. Lat. 49. 6. Long. 1. 22. E.

VERONA, a delegation or province of Austrian Lombardy, within the government of Venice. It is bounded on the north by the Tyrol, on the north-east by Vicenza, on the east by Padua, on the south-east by Polesina, on the south by Mantua, and on the west by the lake of Garda, which divides it from Brescia. It extends over 1320 square miles, and contains 277,849 inhabitants, all Catholics, and all, excepting those in thirteen mountain communes, who speak a corrupt German, being of the Italian race. On the north, this province is partly occupied by the Tridentine Alps, which extend in a circular form to the river Adige. The vicinity of the lake of Garda is also mountainous; but th other portions of the province, between the Adige and th Mincio, belong to the extended plains of Lombardy. Besides the rivers now mentioned, it is watered by the Tartaro the Castagnaro, and the Polesina, which all finally empt themselves into the Po. Much of the land is sterile; but i the south-west a part of it is moderately fertile, producin wheat, maize, rice, rye, flax, hemp, wine, and fruits of variou kinds. A large quantity of silk is produced, and that product has been and still is increasing with the new mulberr trees planted from year to year. The woods provide timber, and the lakes and rivers abundance of fish. Some copper and some coal mines are worked, though not extensively. Of the wealth of this province, a very considerabl portion is drawn from the quarries of marble and alabaste of which a great variety is raised, especially some of a gree colour, very highly estimated.

VERONA, a city, the capital of the delegation of th name. It stands on the river Adige or Etsch, by whic it is divided into two unequal parts, and over which is fine stone bridge of three arches, as well as three other It is surrounded with walls defended by bastions, and onc had three castles, St. Felice and St. Pietro in the valle and Castello-vecchio on a hill, all now neglected. Th streets are generally narrow and crooked, and the square or plazas are rather small. The houses are, many of the at least, of vast size, and the best of them, as well as th most eminent public buildings, are the work of the celebrat Palladio. The city contains 8964 houses, with 55,500 inhabitants. Besides the cathedral there are fourteen parochial, and forty-eight other churches. Many of them a ornamented with the best paintings. The celebrate Ascension of the Virgin by Titian, is in the cathedra This city abounds with Roman antiquities; and amon the most remarkable of them is the amphitheatre. It w constructed under the reign of the emperor Domitiar but an Italian antiquary, named Giuliari, maintains th the original foundation was an Etruscan work of very remote date. The exterior has at present rather a ruino appearance, but the interior is in excellent preservatic though the place is disfigured by the erection of a sm wooden theatre on the arena. It is of an oval form, a the arena or stage is 225 feet long, and 135 feet broa From it arises, over each other, forty-eight rows of sea with passages by steps between these at intervals. T seats and steps are of marble. According to one writer, can seat 22,000 spectators, but others have calculated spa for a greater number, and one of them, Krickel, makes capable of seating 32,824. The access to the seats is eas and the passages leading to them are spacious. It is ke in good repair, and when any part is broken or damage it is replaced.

VERSAILLES, a city of France, the capital of an arro dissement of the same name, in the department of the Sei and Oise, which extends over 331 square miles, is divid into eight cantons, and those into 114 communes, contai ing, in 1836, 133,551 inhabitants. This city is extensive, divided into the new and the old town, is splendidly bui and, by the magnificence of its appearance, must have be very appropriate for the circumstances of France, when state of society was different from what now exists; wh there were nobles to occupy the splendid mansions, a more than 80,000 inhabitants of all classes. The pala was built by Louis XIV., between the years 1673 a 1680. It is a most magnificent and extensive pile of buil ing, decorated with the remains of that correct and chas style of architecture which was the prevailing taste of t time in which it was erected. It is however in a dila dated condition, and its noble apartments destitute of fi niture, and almost of occupants. The gardens are in tol ab preservation, and especially the water-works, the exhi tion of which on Sundays and holidays, still draws to V sailles a large proportion of the more vulgar of the P sians. In 1836, the inhabitants of Versailles amounted to 9,209, among whom are many English and other foreign fa lies, drawn to it by the cheapness with which the ornam ntal parts of education can be obtained. Some manufa ures have been introduced, especially for fire-arms of th most luxurious kind; besides which many watches are m le, some cotton goods, and many smaller articles. It is th place where, in 1783, was signed the peace with Engla ,by which the independence of America was established. L 48. 48. 21. Long. 2. 1. 17. E.

ERSE, in *Poetry*, a line consisting of a number of lo ; and short syllables, which run with an agreeable cad ce.

VERSETZ, a city of Hungary, the capital of a circle of th same name in the province of Hither Theiss. It is the se of a Greek bishop, and a place of great industry, having la e silk mills, and an extensive trade in wine, corn, rice, si and other commodities. Here are extensive barracks fc cavalry. It contains many churches, 2600 houses, and 1 200 inhabitants. Lat. 45. 4. 6. Long. 21. 13. 40. E.

VERT, in *Heraldry*, the term for a green colour. It is c ed *vert* in the blazon of the coats of all under the deg e of nobles; but in coats of nobility it is called *emerald;* a in those of kings *venus.* In engraving it is expressed b diagonals, or lines drawn athwart from right to left, from tl dexter chief corner to the sinister base.

VERTEX denotes the crown of the head. Hence vert is also used figuratively for the top of other things; tl s we say, the vertex of a cone, pyramid, &c.

VERTEX is also used in *Astronomy* for the point of the h ven directly over our heads, properly called the *zenith.*

VERTICILLUS, a mode of flowering, in which the fl vers are produced in rings at each joint of the stem, with v y short foot-stalks. The term is exemplified in mint, h ehound, and other plants.

VERTICITY, is that property of the loadstone whereby it urns or directs itself to one particular point.

VERTOT, RENE AUBERT DE, a lively and elegant, t ugh not a very profound or accurate historian, was born a he castle of Benetot in Normandy, on the 25th of Nov nber 1655. He was the second son of a gentleman al l to several distinguished families, but possessed of little c no fortune. He was educated in the College of the Jes s at Rouen; and having made choice of the ecclesiasti profession, he secretly withdrew from this seminary, and, a r an interval of ten months, his family ascertained that had betaken himself to the convent of the Capuchins, at gentan. He was not however to be diverted from his ign; and having made his profession, he assumed the ne of Brother Zachary. But the austerities of this or were so prejudicial to his health, that he was induced exchange it for one of milder rules. Having obtained a ef from the pope, he entered the abbey of the Præmon tenses at Valsery in 1677. He became secretary to Col t, general of the order, who nominated him prior of yenval. The canon law prohibits a person who has tted one order, from obtaining any office or benefice in other; and although he had procured a dispensation in e form, he yet encountered so much opposition, that he s induced to exchange his priory for a cure, depending the order, at Croissy-la-Garenne, near Marly. Here, at age of thirty-four, he produced his earliest work, " His re des Révolutions de Portugal." Paris, 1689, 12mo. He erwards obtained another cure in his native district of ux; and this he exchanged for a third, in the immediate inity of Rouen. His last benefice was amply endowed, d rendered him very easy in his circumstances. He con ued his historical labours with new ardour, and produced various other works. His next work bears the title of " Histoire des Révolutions de Suede." 1696, 2 tom. 12mo. In 1710, he published his " Traité de la Mouvance de Bretagne." A more elaborate work is his " Histoire des Révolutions arrivés dans le Gouvernment de la République Romaine." 1719, 3 tom. 12mo. The grand-master of Malta had appointed him historiographer of the order, with the privilege of wearing its cross. In order to evince himself worthy of the honour which had thus been conferred upon him, he produced a copious work, entitled "Histoire des Chevaliers Hospitaliers de S. Jean de Jerusalem, appellez depuis les Chevaliers de Rhodes, et anjourd'hui les Chevaliers de Malte." 1726, 4 tom. 4to. Other honours had likewise been bestowed upon him. He became an associate of the Académie des Inscriptions et Belles Lettres. He was appointed "Secrétaire-interprète," and afterwards "Secrétaire des commandements," to the duchess of Orleans. He had apartments in the royal palace, and received a considerable salary. But these honours and emoluments could not secure the enjoyment of good health, and the latter years of his life were passed in much bodily infirmity. He died on the 15th of June 1735, in the eightieth year of his age. Some of his dissertations are to be found among the *Mémoires* of the Academy. A posthumous publication of Vertot appeared under the title of " Origine de la Grandeur de la Cour de Rome; et de la Nomination aux Evechés et aux Abbaies." Lausanne, 1745, 12mo. On the constitution of the Roman senate, he had been consulted by Lord Stanhope; and in 1758 his answer was published by Hooke, who added his own observations.

VERTUMNUS, in *Mythology*, a god who presided over gardens and orchards, honoured among the Etruscans, from whom the worship of this deity was transmitted to the Romans. Vertumnus had a temple near the market-place at Rome, being represented as one of the tutelary deities of the merchants. The commentators on Ovid say, that he was an ancient king of Hetruria, who, by his diligent and successful cultivation of fruit and gardens, obtained the honour of being ranked among the gods.

VERULAM. FRANCIS BACON, VISCOUNT ST. ALBANS, AND BARON VERULAM. This illustrious man was born in London, on the 22d day of January 1561. His father, Sir Nicholas Bacon, a courtier, a lawyer, and a man of erudition, stood high in the favour of Queen Elizabeth, and was lord-keeper during twenty years of her reign. Anne, the second wife of Sir Nicholas, and the philosopher's mother, was the daughter of Sir Anthony Cooke, Edward the Sixth's tutor, and was herself distinguished among the learned females of the time. One of her sisters became the wife of Elizabeth's celebrated treasurer, Lord Burleigh. Delicate in health, and devoted to sedentary employment, Francis Bacon exhibited in early boyhood the dawning of those powers whose versatility afterwards became not less remarkable than their strength. As a child he delighted the queen with his precocious gravity and readiness of speech; and before he had completed his twelfth year we see him investigating the cause of a singular echo in a conduit, and endeavouring to penetrate the mystery of a juggler who performed in his father's house. At the age of thirteen he was matriculated at Trinity College, Cambridge, of which Whitgift was then master; but his residence at the university lasted scarcely three years, and his writings contain many expressions of dissatisfaction with the current system of academical education. In his sixteenth year he was sent abroad, and lived for some time at Paris, under the charge of the English ambassador, Sir Amias Paulett; after which he visited the French provinces, and added to his literary and philosophical studies an acquaintance with foreign policy and statistics, the fruit of which soon appeared in his tract upon the State of Europe. In February 1580, his father died, and he immediately returned to England.

Sir Nicholas left but a scanty fortune; and his son Francis, the youngest of a large family, found himself obliged, in his twentieth year, to devise the means of earning a livelihood. One would have thought powerful friends could not have been wanting to one who, besides his own acknowledged merit, had it in his power to urge the long and honourable services of his father, while his uncle was the prime minister of the kingdom. Of the patronage which thus seemed to be at his command, Bacon attempted to avail himself, desiring to obtain such a public employment as might enable him to unite political activity in some degree with literary study. But his suit was received neglectfully by the queen, and harshly repulsed by his kinsman. Although all the causes of this conduct may not be discoverable, a few lie at the surface. The lord-keeper had, in the later years of his life, lost the royal favour. Burleigh, besides his notorious contempt for men of letters, had to provide for sons of his own, to whom their accomplished cousin might have proved a dangerous rival. From the Cecils, indeed, Bacon never derived any efficient aid, till he had forced his way upwards in spite of them; and there are evident traces of jealousy and dislike in the mode in which he was treated both by the old treasurer, and by his second son, Robert.

Obliged therefore to betake himself to the law, Bacon was admitted at Gray's Inn, where he spent several years obscurely in the study of his profession, but with increasing practice at the bar. The friendship of his fellow lawyers, earned by his amiable disposition and his activity in the affairs of the society, bestowed on him offices in his inn of court; but his kinsmen were still cold and haughty. Lord Burleigh continued to write him letters of reproof; and Robert Cecil, already a rising statesman, sneered at speculative intellects, and insinuated their unfitness for the business of life. In 1590, when Bacon was in his thirtieth year, he was visited for the first time with court-favour, receiving then an honorary appointment as queen's counsel extraordinary; and to this was added a grant of the reversion of a clerkship in the star-chamber, which did not become vacant for eighteen years. But the lawyer's heart was not in his task. His brilliant professional success, and the awakening friendship of his relations, merely suggested to him renewed attempts to escape from the drudgery of the bar. His views are nobly expressed in a letter which he addressed to the lord-treasurer the year after his appointment.[1] We linger with melancholy pleasure over these abortive efforts made by one of the finest and most capacious of intellects to extricate itself from that labyrinth of worldly turmoil, in which its owner was destined to purchase rank and splendour at the expense of moral degradation and final ruin.

We are henceforth to behold Bacon actively engaged in political life, as well as in the duties of his profession. Two parties then divided the court, equally remarkable in different ways on account of those who headed them. Burleigh was the chief of the queen's old counsellors, on whom, amidst all her caprices, she always had the prudence to rely for the real business of the state: the young and gay, those who aspired to be ranked as the personal friends or adorers of the withered sovereign of hearts, were led by the high-spirited and imprudent Earl of Essex. To the party of this nobleman Bacon decidedly attached himself, and soon indeed shared with his own elder brother Anthony, the earl's most private confidence. Valuable advisers were they to their rash patron; and a valuable servant of the nation did Francis Bacon bid fair to become, when, in November 1592, he entered parliament as one of the knights of the shire for Middlesex. His first speech, in February following, contained an urgent pleading for improvements in the law; in another address, delivered in March, he resisted, with exceeding boldness as well as force of reason, the immediate levying of an unpopular subsidy to which the House had already consented. The young lawyer's exposition of unpleasant truths gave deep offence to the queen. His uncle and the lord-keeper were both commissioned to convey to him the assurance of the royal displeasure; and the two humble, nay, crouching letters of apology, still extant, in which he entreated those ministers to procure his pardon, did not forebode much independence in his subsequent conduct. We do not, indeed, again hear Bacon named as a champion of popular rights.

In the year 1594, Sir Edward Coke being made attorney-general, the solicitorship became vacant; and Bacon's application for the office was strenuously supported by Essex. But all efforts were in vain. The powerful kinsmen were colder than ever towards one who had chosen another patron. The lord-keeper, Puckering, acted in a manner which drew on him a spirited rebuke from the candidate. The queen hesitated, coquetted, told Essex that his friend, though witty, eloquent, and in some branches learned, was a showy lawyer rather than a profound one. After a delay of many months, the place was given to a plodding serjeant; and Bacon's generous patron, vexed at the disappointment of his hopes, sought to console both him and himself by a gift equally munificent and delicate. Bacon received from him an estate at Twickenham, worth about eighteen hundred pounds. The present, in all likelihood, came very seasonably; for he appears to have been already involved in those pecuniary embarrassments from which he was never afterwards completely able to extricate himself. He was obliged to sell the land which Essex had given him; two years later he was arrested in the street for a debt of three hundred pounds; and among the Lord Chancellor Ellesmere's papers, recently published, there is a curious acknowledgment, granted in 1604, for a pledge in security of an advance of fifty pounds to him. These reasons offer the only apology for the addresses which, about the time of his arrest, he paid to a wealthy and shrewish widow, who, fortunately for him, preferred his professional brother and personal enemy, Sir Edward Coke. In the meantime, his legal reputation continued to increase, and his parliamentary exertions were unremitted, though altogether free from that independence which had once characterized them. We thus trace Bacon down to his thirty-n ch year, pausing only to remark, that two years earlier, th t is, in 1597, his celebrated Essays were first published. A hough merely the skeleton of what they afterwards became, these compositions gained high reputation for their a hor, not only at home, but also on the continent.

---

[1] "I wax now somewhat ancient: one-and-thirty years is a great deal of sand in the hour-glass. My health, I thank God, I find confirmed, and I do not fear that action shall impair it; because I account my ordinary course of study and meditation to be more painful than most parts of action are. I ever bear a mind, in some middle place that I could discharge, to serve her majesty; not as a man born under Sol that loveth honour, nor under Jupiter that loveth business, for the contemplative planet carrieth me away wholly; but as a man born under an excellent sovereign, that deserveth the dedication of all men's abilities. . . . Again, the meanness of my estate doth somewhat move me; for, though I cannot accuse myself that I am either prodigal or slothful, yet my health is not to spend, nor my course to get. Lastly, I confess that I have as vast contemplative ends, as I have moderate civil ends; *for I have taken all knowledge to be my province*; and, if I could purge it of two sorts of rovers,—whereof the one with frivolous disputations, confutations, and verbosities, the other with blind experiments, and auricular traditions and impostures, have committed so many spoils,—I hope I should bring in industrious observations, grounded conclusions, and profitable inventions and discoveries; the best state of that province. This, whether it be curiosity, or vain-glory, or nature, or (if one take it more favourably) philanthropia, is so fixed in my mind, as it cannot be removed. . . . *And if your lordship will not carry me on*, I will not do as Anaxagoras did, who reduced himself with contemplation into voluntary poverty: but *this I will do,—I will sell the inheritance that I have, and purchase some lease of quick revenue, or some office of gain, that shall be executed by deputy; and so give over all care of service, and become some sorry bookmaker, or a true pioneer in that mine of truth, which, he said, lay so deep.*"—(Cabala, p. 18. Bacon's Works, vol xii. p. 6, 7. Montagu's edit.)

After this, the first step in Bacon's literary career, we a roach what is the most painful task of his biographer, a dark page of his history, over which no ingenuity has e r been able to throw a veil thick enough to disguise it foulness. We have seen him the friend, the adviser, th grateful vassal of Essex; we are now to behold him d erting his benefactor, assisting to destroy him, standing f h in the face of the world as his enemy and accuser. The p losopher's latest biographer has pronounced his conduct i this matter to be honourable and praiseworthy; and to his p es we must refer those who are curious to canvass arg ments of which we are ourselves unable to discover the f ce. Bacon, unfortunately for himself, had lately risen m ch in royal favour, and been greatly trusted and employed. A cordingly, in the first stages of Essex's decline, he had to a a double part,—now offering to his patron advices which w e but seldom followed, now seeking excuses to pacify t queen's rising displeasure. His natural inclination for t porizing, the success which had hitherto attended his c tious policy, the honest wish to serve his generous friend,—a these reasons may have concurred in tempting him to e bark in the dangerous channel. But the sunken rocks s n encompassed him, and shipwreck was unavoidable. ienation either from Elizabeth or from Essex speedily peared to be the necessary result of the position into ich the parties were coming. Bacon had not the courage take the nobler part, and place himself by the side of falling friend, at the probable expense of all his worldly ospects. Suspicion and estrangement soon took the place affectionate confidence; and the trust reposed in him by e queen was purchased by the bitter consciousness that Esx regarded him as treacherous and hostile. A more deading task was yet to come The first trial of the earl, in erence to his conduct in Ireland, was determined upon; d Bacon's enemies asserted that he offered himself to act one of the counsel for the prosecution. In that memoir defence of his conduct which he wrote in the next reign, d which proves satisfactorily nothing but his own humiting consciousness of guilt, he states as to this matter at was doubtless the truth. It had been resolved that e proceedings against the rash earl should not be carried t to his destruction, but should only disarm and disurage him; and, a hint being conveyed to Bacon that e queen had not determined whether he should be emoyed professionally in the affair or not, he thought proper address to her "two or three words of compliment," innating that if she would dispense with his services he ould consider it as one of her greatest favours, but that herwise he knew his duty, and would not allow any prite obligations to interfere with what he owed to her ajesty. All this was, he adds, "a respect no man that d his wits could have omitted." Bacon, in short, still ished to serve two masters; but he had now placed himlf at the mercy of those from whom he had no forbearance expect. The queen, suspicious and moody, was jealous his attachment to Essex, and bent on compelling him to her service unreservedly: her advisers, or some of them, ere glad to have the odium of the earl's destruction shared ith them by one so distinguished, who had, likewise, been e victim's friend. It was intimated that Bacon's services uld not be dispensed with; but he tells us, (and he proably repeats only what his masters tried to make him elieve), that it was resolved his share in the prosecuon should be confined to matters which could not do his nfortunate patron any serious harm. Essex's private cenure by the privy-council followed; and, while he was committed to custody-at-large, Bacon incurred, by his appearance against him, an obloquy of which his letters show him to have been painfully sensible. In a few months the earl's open rebellion took place; he was seized, and put upon his trial in February 1601, along with Lord Southampton; and on this occasion, when his life was at stake, Bacon again appeared as one of the counsel for the prosecution, and delivered a speech of which there is extant an imperfect account. The language is harsh, but less so than addresses of the kind used to be in those days. The topics are oratorical, and, as it has been justly remarked, are less calculated for ensuring conviction (which indeed was certain) than for placing the conduct of the prisoner in an odious light, and hardening the queen's heart against him; and, although it would be rash to judge of the real temper of the harangue without knowing more of its contents, yet what we possess contains much that cannot possibly be explained so as to do credit to the speaker. We know, likewise, how the object of the attack received it. At one place Essex interrupted his treacherous friend, and called upon him to say, as a witness, whether he had not, in their confidential intercourse, admitted the truth of those excuses which he now affected to treat as frivolous and false. Essex was convicted; and between his sentence and execution, Bacon admits in his exculpatory memoir that he made no attempt to save him; seeing the queen but once, as he says, and on that occasion venturing to do nothing further than pronouncing a few common-places on the blessed uses of mercy. But not even here was the disgrace to end, in which the timid man of the world had steeped himself. The act which had cost Elizabeth's own heart so much, had also made her unpopular; a defence of the royal policy in regard to Essex was thought necessary, and the pen that drew it up, under the direction of the queen's advisers, was, we are grieved to find, no other than Bacon's. The "Declaration of the Practices and Treasons attempted and committed by Robert Earl of Essex," was printed, and is extant: "a performance," says a late writer, "in defence of which, in the succeeding reign, Bacon had not a word to say; a performance abounding in expressions which no generous enemy would have employed respecting a man who had so dearly expiated his offences." With this humiliating act of service we may consider Bacon's public life under Elizabeth as closed.

The reign of her successor was, from its commencement, a more auspicious era for men of letters and philosophy, with whom James, amidst all his imbecility and cold-heartedness, was not by any means ill fitted to sympathise. Bacon's learning was no longer open to sneers and contempt; his uncle was dead; his hunchback cousin, Robert Cecil, who soon became Earl of Salisbury, was kept in check by his hereditary prudence; and Coke, who had insulted our philosophic lawyer grossly, as he insulted every one who was defenceless and within his reach, was in a few years removed to the head of the court of common pleas. From the first hour of James's reign, Bacon lost no opportunity of recommending himself to favour; but the first mark of it which he received, was one of which he neither was nor could have been proud, and which, nevertheless, he thought proper to solicit. When the king called upon all persons possessing forty pounds a year in land to be knighted, or to compound for a dispensation from the honour, one effect of this scheme for filling the royal coffers was, that three members of Bacon's mess at Gray's Inn appeared among the new knights. That love of external distinctions which was the fatal weakness of his nature, was called into play, and the philosopher was disconcerted by the titles of his companions, beside whom he sat untitled. At the same time, likewise, he had, in his own words, "found out an alderman's daughter, a handsome maiden, to his liking;" and the alderman's daughter was likely to be more easily won if her admirer could offer her a showy accession of rank. Accordingly, Bacon wrote to his cousin Cecil, stating his desire to obtain, for these reasons, "this divulged and almost prostituted title of knighthood." The request was granted, but was immediately followed by another. Bacon, heartily ashamed of the company in which he was to appear, entreated that he might be knighted alone; "that," as he says, "the manner might be such as might grace one, since the matter will not." This petition was refused; and, on the day of the coronation, Francis Bacon was one of three hundred who received the empty honour. Soon afterwards, being forty-two years old, he was married to the alderman's daughter, Alice Barnham, who brought him a considerable fortune, but seems, in the latter part of his life at all events, to have contributed little to his domestic happiness.

These details are in themselves trifles; but they are strange illustrations of the mixed character of one who, while thus soliciting honours of which he was half-ashamed, and eager for public distinctions, which, though more solid, were likewise more dangerous, was not only respected and distinguished as a lawyer and a statesman, as an orator, a scholar, and an author, but was occupied, during his few hours of leisure, in completing the most valuable system of philosophy that has ever been expounded in modern Europe. Smaller compositions, submitted to his friends, showed from time to time the progress of the great work which he had marked out as the business of his life; and among these was the treatise on the Advancement of Learning, published in 1605, in its author's forty-fifth year. Political tracts alternated with these philosophical speculations.

In the mean time his public reputation, and his favour with the king, increased and kept pace with each other. In parliament he was actively useful in forwarding favourite and really good measures of the court, such as the union of England and Scotland, and the proposed consolidation of the laws of the two countries; nor was he less usefully employed in taking a prominent part in the select committee of the house upon grievances. In his skilful hands, the report became all that the rulers could have wished, without exciting any general feeling against the framers. In 1604, he was made king's counsel in ordinary, with a salary of forty pounds, to which was added a pension of sixty pounds. In 1607, upon Coke's promotion to the bench, Bacon was appointed solicitor-general; and he became attorney-general in 1612. His treatises concerning improvements in the law, and the principles of legislation, are more creditable testimonies to the value of his official services than some others of his acts; such as the scheme, first tried in the session of 1614, for securing majorities in the House of Commons by organised corruption, the invention of which has been recently traced to him, although in his place in parliament he ridiculed those who asserted that such a project had ever been formed. Bacon was likewise officially the prosecutor of Oliver St. John, of Owen and Talbot, and of the old clergyman Peacham, who was examined in the Tower under torture, the founder of modern philosophy being present, and putting the questions. In Peacham's case there was even an attempt, actively promoted by Bacon, for securing a conviction by previous conference with the judges; a plot which, though at length successful, was defeated for a time by the sturdy resistance of Coke, a tyrant to his inferiors, but a staunch opponent of encroachments upon judicial independence. Bacon's last remarkable appearance as attorney-general, was in the noted trial of the earl and countess of Somerset and their accomplices, for the murder of Sir Thomas Overbury; and, whatever the foul secret may have been, which was involved in that fiendish intrigue, Bacon's letters to the king leave little reason for doubting that he at least was in possession of it. His conduct in this matter however gained him great and deserved credit.

The fall of Somerset was followed by the rise of the new favourite Villiers, who had already profited by his intimacy with the attorney-general, and by the sound advices with which the cautious statesman endeavoured to fortify his youth and inexperience. The worthless Buckingham, destined in a few years to be the instrument of retribution for Bacon's past desertion of Essex, did not for some time forget obligations, of which he was probably wise enough to desire a continuance. In 1616 Bacon having been sworn of the privy council, relinquished the bar, but retained his chamber practice. In the spring of 1617, the Lord Chancellor Ellesmere resigned the seals, which were immediately delivered to Bacon, with the title of lord-keeper. In January of the succeeding year he was made lord high chancellor of England, and in July was raised to the peerage as Baron of Verulam. His higher title of Viscount St. Albans was not conferred on him till 1621. Without neglecting his political duties, he proceeded zealously to the judicial functions of his office, in which arrears of business had accumulated through the infirmities of his aged predecessor. "This day," wrote he to Buckingham in June 1617, "I have made even with the business of the kingdom for common justice; not one cause unheard; the lawyers drawn dry of all the motions they were to make; not one petition unanswered. And this, I think, could not be said in our age before. Thus I speak, not out of ostentation, but out of gladness, when I have done my duty. I know men think I cannot continue, if I should thus oppress myself with business; but that account is made. The duties of life are more than life: and if I die now, I shall die before the world be weary of me." And the man who wrote in this solemn moral strain, the man whose writings throughout are an echo of the same lofty expression of the sense of duty, was also the man who, in less than four years after his elevation to the seat of justice, was to be hurled from it in disgrace, branded as a bribed and dishonest man. "At York House," says Mr. Montagu, "on the 22d of January 1621, he celebrated his sixtieth birthday, surrounded by his admirers and friends, among whom was Ben Jonson, who composed a poem in honour of the day

> Hail, happy genius of this ancient pile!
> How comes it all things so about thee smile—
> The fire, the wine, the men—and in the midst
> Thou stand'st, as if some mystery thou didst?

"Had the poet been a prophet, he would have described the good genius of the mansion not exulting, but dejected humble, and about to depart for ever."

He had now arrived at the conviction that his worship o the powers of this world had made it impossible for him t consummate the great sacrifice, which, during his lifetime, h had hoped to lay upon the altar of philosophy. Aged sixt years, and immersed in difficult and anxious business, h felt that his great Restoration of Science, his Instauratio Magna, could not be completed; and he therefore hastene to give to the world an outline of its plan, coupled with a filling up of one section of the outline. "I number my days," wrote he, "and would have it saved." The Novum Orga num, the result of this determination, was published i October 1620; and the fame which it earned for its autho throughout Europe, was in its rising splendour when his fal took place.

The tempest which was soon to overturn the throne wa already lowering on the horizon; and its earliest muttering were heard in the important parliament which met on th 30th of January 1621. With most of the complaints whose investigation the king and Buckingham feared s much, we have here little to do: but two gross abuses ther were, in which the lord chancellor was personally implicated He had passed the infamous patents of monopoly, of whic the worst were those held by Sir Giles Mompesson, (Massinger's Overreach,) and by Sir Francis Michell, and shared b Buckingham's brothers and dependents: and he had allowed himself to be influenced in his judicial sentences by re

Verulam.

ommendations of the favourite. The first of these faults dmitted of palliation, the second was susceptible of none; it both were real and heavy offences. Yet neither of them as made an article of charge against Bacon. He was atcked upon a different ground. Buckingham, by the advice 'his new counsellor Williams, then dean of Westminster, bandoned the monopolists to their fate, contenting himself ith sending his own brothers out of the country, and with terwards publicly denying that he had any hand in assistg their escape. But the storm was not allayed. In March, e parliamentary committee appointed to inquire into the cistence of abuses in the courts of justice, reported that buses did exist, and that the person against whom they were leged, was the lord chancellor himself. Two cases were ecified, of suitors named Aubrey and Egerton, of whom e one had given the chancellor L.100, the other L.400, id against whom he had decided, notwithstanding these esents. Two days after this report was presented, Lord t. Albans presided in the House of Lords for the last time. ew accusations accumulated against him; and, alarmed in ind, and sick in body, he retired from the house, and adressed to the peers a letter, praying for a suspension of eir opinion, until he should have undergone a fair trial. In o long time the charges against him amounted to twentyiree; and Williams, again called to the councils of Buckingam and his master, advised that no risks should be incurred pon his account. A prorogation of parliament ensued, durig which an interview took place between the king and the hancellor; and James, instead of encouraging his accused ervant in the resolution he had expressed of defending imself, recommended "that he should submit himself to ie House of Peers, and that upon his princely word he ould then restore him again, if they in their honours should ot be sensible of his merits." On the 24th of April there as presented to the Lords, by the Prince of Wales, a supplication and submission of the lord chancellor, in which ie most important passage is the following: "It resteth, herefore, that, without fig-leaves, I do ingenuously confess nd acknowledge that, having understood the particulars of ie charge, not formally from the house, but enough to inorm my conscience and memory, I find matter sufficient nd full, both to move me to desert my defence, and to move our lordships to condemn and censure me. Neither will trouble your lordships by singling those particulars, which think may fall off.

Quid te exempta juvat spinis de pluribus una?

Neither will I prompt your lordships to observe upon the roofs, where they come not home, or the scruples touching he credits of the witnesses: neither will I represent unto our lordships how far a defence might, in diverse things, xtenuate the offence, in respect of the time or manner of he gift, or the like circumstances; but only leave these hings to spring out of your own noble thoughts, and obserations of the evidence and examinations themselves, and haritably to wind about the particulars of the charge here nd there, as God shall put in your minds; and so submit nyself wholly to your piety and grace. . . . . And, thereore, my humble suit to your lordships is, that my penitent ubmission may be my sentence, and the loss of the seal my unishment; and that your lordships will spare any further entence, but recommend me to his majesty's grace and paron for all that is past." But not even thus was the humiliaion complete. The house resolved that the submission was ot specific, nor unequivocal enough to be satisfactory; and hat he should be required to furnish categorical answers to the several articles of charge, which, accordingly, were sent to him, being numbered under twenty-three heads. The pecific answers which he returned were prefaced and followed by these declarations: "Upon advised consideration of the charge, descending into my own conscience, and calling my memory to account, so far as I am able, I do plainly and ingenuously confess that I am guilty of corruption, and do renounce all defence, and put myself upon the grace and mercy of your lordships. . . . . This declaration I have made to your lordships with a sincere mind; humbly craving that, if there should be any mistakes, your lordships would impute it to want of memory, and not to any desire of mine to obscure truth, or palliate anything. For I do again confess, that in the points charged upon me, although they should be taken as myself have declared them, there is a great deal of corruption and neglect, for which I am heartily and penitently sorrow, and submit myself to the judgment, grace, and mercy of the court.—For extenuation, I will use none, concerning the matters themselves: only it may please your lordships, out of your nobleness, to cast your eyes of compassion upon my person and estate. I was never noted for an avaricious man, and the apostle saith, that covetousness is the root of all evil. I hope also that your lordships do the rather find me in the state of grace; for that, in all these particulars, there are few or none that are not almost two years old, whereas those that have an habit of corruption do commonly wax worse and worse; so that it hath pleased God to prepare me, by precedent degrees of amendment, to my present penitency. And for my estate, it is so mean and poor, as my care is now chiefly to satisfy my debts."

This declaration being read, a deputation of the lords was appointed to wait on the unfortunate man in the chamber where he sat deserted and alone, and to demand whether it were his own hand that was subscribed to it. Among them was Shakspeare's friend Lord Southampton, who had been condemned to death along with Essex. Bacon replied to them, "It is my act, my hand, my heart. I beseech your lordships, be merciful unto a broken reed." Again the fallen judge prayed the king to intercede for him; and again the king, his haughty son, and their thankless favourite, refused to interfere. On the 3d of May 1621, the lords pronounced a sentence which, stamping him at all events with indelible disgrace, was terrible even in the punishment which it actually inflicted. Bacon, found guilty upon his own confession, was sentenced to a fine of forty thousand pounds, and to confinement in the Tower during the king's pleasure; he was pronounced incapable of public employments, and of sitting in parliament; and prohibited from coming within the verge of the court. His judges indeed knew that the harsher part of the sentence would not be executed. Accordingly, though committed immediately to the Tower, he was released after two days' imprisonment; and the fine was remitted in the course of the autumn, although it is a fact dishonourable (in the circumstances) to his enemy and successor Bishop Williams, that the pardon was stayed at the seal, till the king in person ordered it to be passed.

From the whole tenor of this afflicting history, it is plain that Bacon's memory cannot be cleared from very heavy imputations. Indeed, the case against him may be stated, if we push it to the utmost, in an alternative form which admits of no honourable solution. Convicted of corruption, as he was, upon his own confession, we must either believe the confession, and pronounce him a corrupt judge, or we must disbelieve it, and pronounce him a liar. Most of his biographers adopt the former alternative. Mr. Montagu's elaborate defence is really founded on something which is not very far distant from the latter. And, humiliating as either supposition is, we have, for our own part, no hesitation in believing that the truth lies nearest to that theory which imputes to the unhappy chancellor insincerity and cowardice rather than wilful corruption. We cannot indeed go so far as his enthusiastic biographer, who insists that the acts charged and confessed, were in themselves, if not quite free from moral blame, yet palliated, not only by general usage, but by intentions strictly honest;—that he was sacrificed by the king and the king's minion, although, if he had stood a trial, he could have obtained a full acquittal. This, we must venture to think, is a position which, if maintained to its whole extent, cannot be even plausibly defended. Neither, as we must also believe, is justice done by that other view, which has been stated more recently with such force and eloquence, that the case was one of gross bribery, gross and glaring even when compared with the ordinary course of corruption in these times; a case so bad, that the court, anxious, for their own sakes, to save the culprit, dared not to utter a word in extenuation.[1]

The fact which possesses the greatest importance for the elucidation of this unfortunate story, is that which has been founded on so elaborately by Mr. Montagu, and lately illustrated further by another writer for a different purpose.[2] The custom of giving presents was then general, not to say universal, in England. It extended much farther than the *épices* of the French parliaments; for the gifts were not fixed in amount, nor, though always expected, were they recognised as lawful perquisites. The advisers of the crown received presents from those who asked for favours: the sovereign received presents from those who approached the throne on occasions of pomp and festivity. Both these improprieties were not only universal but unchallenged. Further, judges received presents; and under certain conditions,—when, for instance, the giver had not been, and was not likely to be, a suitor in the judge's court, or even when, though he had been a suitor, the cause was ended,—this dangerous abuse was scarcely less common than the other, and scarcely regarded in a more unfavourable light. That it was wrong, all men felt; but we fear there were few indeed, who, like Sir Thomas More, refused absolutely to profit by it. High as Coke himself stood for honesty, and well as he deserved praise for this (almost his only redeeming virtue), we doubt whether his judicial character could have emerged quite untainted from a scrutiny led by common informers, discarded servants, and disappointed litigants, like that to which his unfortunate rival was subjected. Pure Bacon was not; purer than he, several of his contemporaries probably were; but we believe him to have been merely one of the offenders, and very far indeed from being the worst, in an age when corruption and profligacy, senatorial, judicial, and administrative, were almost at the acme of that excess which an indignant nation speedily rose to exterminate and to avenge.

A comparison of the charges in detail, and of the evidence adduced, with Bacon's articulate answers, as to the candour of which there is no reason to doubt, would really exhibit little or nothing which, after fair allowances are made for imperfect information and other causes of obscurity, would afford a distinct contradiction to the chancellor's own solemn averment, made in a letter to the king at an early stage of the investigation. "For the briberies and gifts wherewith I am charged, when the book of hearts shall be opened, I hope I shall not be found to have the troubled fountain of a corrupt heart, in a depraved habit of taking rewards to pervert justice; howsoever I may be frail, and partake of the abuses of the times." While he lay in the Tower, he addressed to Buckingham a letter containing these expressions: "However I have acknowledged that the sentence is just, and for reformation sake fit, I have been a trusty, and honest, and Christ-loving friend to your lordship, and the justest chancellor that hath been in the five changes since my father's time." This last sentence, indeed, when carefully weighed, will be found to contain more of truth than the writer himself perhaps intended. A judge not altogether unjust he may have been, if we compare him with his contemporaries; but he was also a trusty, and trusting, and servile friend of the royal favourite, and of other men in power. He was a lover of the pomp of the world, to an extent highly dangerous for one who had but little private fortune, insufficient official remuneration, and habits which disqualified him for exercising a strict superintendence over the expenses of his household, or the conduct of his dependents generally. His emoluments as chancellor did not amount to three thousand pounds a-year; and, immediately on his appointment, he had used vain endeavours to have the office put on a more independent footing. His servants habitually betrayed both him and the suitors; but there can be no doubt that, continually embarrassed in circumstances, he himself was only too glad to receive the customary gifts when they could be taken with any semblance of propriety. As to his confession, while we believe it to be true in every particular instance, we believe it also in its general admission of corruption; but we likewise believe that the general admission ought to have been qualified by certain references, which would have established the truth of a remark made by Bacon in his hour of deepest suffering, that "they upon whom the wall fell were not the greatest offenders in Israel." And this, as we conceive it, was the danger which the court were so eager to avert, the danger which filled the king and Buckingham with such dismay. This was their reason for insisting that Bacon should sacrifice his own character, and abandon that line of defence which might not improbably have precipitated the revolution. Upon this assumption, their conduct throughout is intelligible and consistent; and, although one is reluctant to believe it, the assumption is not contradicted by any thing in the chancellor's character. Lofty as may still have been his abstract notions of morality, his practical views were darkened and debased by his long servitude to public office in a corrupt age. The stain which, as he well knew, the sentence of the parliament would affix upon his name, may have seemed a light thing to one who was aware how the same brand might have been justly imprinted on almost every eminent name in the kingdom. And again, neither Bacon nor his master, nor those others who were the royal advisers, were able to comprehend, in this instance, any more than elsewhere, the spirit which had already gone abroad. They did not anticipate the severity of the sentence pronounced by the House of Lords; still less did they anticipate (Bacon at least did not, nor perhaps did Williams) the universal indignation which was aroused by the fact that the highest judge in the realm had been displaced for bribery. The court gained its immediate purpose, in removing to a subsequent time the fatal struggle; but there soon arrived the fulfilment of Bacon's prophecy, that the successful attack on him would be but an encouragement and strengthening to those who aimed at the throne itself.

After his release from the Tower, Bacon, although strangely anxious to continue in London, was obliged to retire to his paternal seat of Gorhambury, near St. Albans. There he immediately commenced his History of Henry the Seventh, a work displaying but too unequivocal proofs of the dejected lassitude which had crept upon his mind. Early in next year he offered himself unsuccessfully for the provostship of Eton College, and proceeded with other literary undertakings. These included the completion of the celebrated treatise, "De Augmentis," an improvement of the older work on the Advancement of Learning. This was the last philosophical treatise which he published; although the few remaining years of his life were incessantly devoted to study and composition, and gave birth to the New Atlantis, the Sylva Sylvarum, and other works of less consequence.

[1] Montagu's Life of Bacon, Works, vol. xvi. part 1. pp. 313—377, *note*. Edinburgh Review, vol. lxv. p. 50—63.

[2] Edinburgh Review, No. 143, p. 38, 39. Life of Raleigh.

Shortly before the king's death, he remitted the whole of e sentence on Bacon, who, however, did not again sit in rliament. His health was already broken; and in De- mber of that year, 1625, he made his will, in which, al- ough his affairs were really in extreme confusion, he writes if he considered himself a wealthy man. In the spring 1626, on his way from Gray's Inn to Gorhambury, he ex- sed himself to a sudden chill, by performing in a cottage experiment which had suggested itself to him, regarding fitness of snow or ice as a substitute for salt in preserv- dead flesh. Unable to travel home, he was carried to the l of Arundel's house at Highgate, where, after seven ys' illness, he died early in the morning of Easter Sunday, 9th of April, in the sixty-sixth year of his age. In obe- nce to his will, he was buried in the same grave with his ther, in St. Michael's church, near St. Albans.

It is sad beyond expression to turn to those reflections ich are suggested by the life of this great man, however iently one may be disposed to regard his weaknesses. who founded the philosophy of modern Europe, he who ought down philosophy from heaven to earth, disentang- g it from airy abstractions, and anchoring it on practical ths,—he who aided science alike by his improvements its procedure, and his enlarged views of its end and aim, licating observation of individual truths as the only sure ide to universal conclusions, and practical utility as the ly quality which makes such conclusions worth the la- ur they cost,—he who did all this, was destined to furnish his own pitiable example, a pregnant illustration of the at principles which his writings taught. A slave to the rld and its vanities, he was betrayed by the evil genius om he served. Unable to subject reason, and passion, imagination, to the stern control of the moral sense, expiated, by a life of discomfort and dependence, ending an old age of sorrow and disgrace, the sin of having mis- prehended the mighty rule, which alone can save the em- e of the mind from becoming a scene like ancient chaos.

Bacon's philosophy has been analysed in other parts of s work, and on his literary character we have left our- ves no space to enlarge. We can only remark the power- effect which his singular versatility of talents exercised er the dissemination of his scientific views. "The re- tation which Bacon had acquired from his Essays," says ate writer, "a work early translated into various foreign guages,—his splendid talents as an orator,—and his pro- nent place in public life,—were circumstances strongly culated to attract the curiosity of the learned world to philosophical writings." And these writings in themselves rtake admirably of the character belonging to their au- or's works of a different class. Philosophy has seldom made rself more attractive; never has she made herself equally in communicating lessons of such sterling value. If the rks of this wonderful man were worthless as repositories scientific thought and knowledge, they would still demand erential study. A masterly eloquence, a union of diver- ed qualities of style in the highest sense of the word, dis- guished even the earlier among them, and entitled those ich were produced in the writer's maturer years, to rank, twithstanding the faults they share with all prose com- sitions of their time, as monuments nowhere excelled in compass of English literature.[1] (B. L.)

VERVEIERS, a circle of the province of Liege, in the therlands, containing six cantons, divided into twenty- e communes. The capital is the city of the same name, ely situated on the river Besdre, partly in a valley, and rtly on the declivity of some hills. It is well built, and lace of the most active industry in the kingdom. The chief trade is that of making fine woollen cloths, which are celebrated in every part of the continent, especially from the brilliant colours, to which the quality of the water is said greatly to contribute. There are also some chemical manufactures, producing aquafortis, vitriol, and soaps. The wealth and number of the inhabitants have rapidly increased since the peace of 1814. The population then was 9960, and in 1831 was 19,592.

VESALIUS, Andreas, a celebrated physician and anatomist, was born at Brussels in the year 1514. He studied physic at Paris under Sylvius, but applied himself chiefly to anatomy, which was then very little known, dissections being esteemed unlawful and impious; and it appears from his work "De Humani Corporis Fabrica," that he perfected himself in this useful knowledge very early. About the year 1537, the republic of Venice made him professor in the university of Padua, where he taught anatomy for seven years. Charles V. called him to be his physician, as he was afterwards to Philip II., king of Spain. Vesalius was now at the height of his glory, when all of a sudden he formed the design of taking a journey to Palestine; concerning which journey we are told the following story. A young Spanish nobleman whom he had attended was supposed to be dead. Vesalius obtained leave to open him, in order to explore the true cause of his illness; but when he opened the breast, he perceived symptoms of life, and saw the heart beat. The parent, not satisfied with prosecuting him for murder, accused him of impiety to the inquisition, in hopes that tribunal would punish him with greater rigour; but the king interposing, saved him on condition of his making a pilgrimage to the Holy Land. He was shipwrecked on his return, and thrown upon the island of Zante, where he perished on the 15th of October 1564. He was the author of several works, the principal of which is entitled "De Humani Corporis Fabrica, libri vii." Basil. 1543, fol. This first edition contains excellent wood-cuts.

VESOUL, a city of France, the capital of an arrondissement of the same name in the department of the Saone. It stands on the river Drugeon, is well built, and is surrounded with hills, whose sides are covered with vineyards yielding very good wine. Around it are some beautiful promenades. In 1836 it contained 5583 inhabitants. Lat. 47. 37. 50. Long. 7. 4. 31. E.

VESPER, a small island in the Pacific ocean, thirty-six miles in circumference, discovered by Roggewin in 1722.

VESPERS, in the church of Rome, denote the afternoon service; answering in some measure to the evening prayers of the church of England.

VESPUCCI, AMERIGO, was born at Florence, 9th March, 1451, of a distinguished family, and was educated by his uncle, a man of great scientific reputation, and made great proficiency, especially in astronomy and geography, and the sciences connected with navigation. He was destined by his family to commercial pursuits, which had at this time contributed so greatly to the prosperity of the republic. In 1493 he left Florence, and arrived at Seville at the time that Columbus was preparing to set out on his first voyage of discovery; the success of which awakened the emulation of Amerigo, and determined him to exchange the pursuits of commerce for the fascinating prospects of discoveries in the New World.

On the 10th of May, 1497, (according to the account of Bandini, but Spanish writers place the date two years later,) he commenced his first voyage, and left Cadiz with five vessels under the orders of D'Ojead. He reached America after thirty-seven days' sailing, and coasted along the continent more than 400 leagues. After a voyage of thirteen months, he returned to Spain, and anchored at Cadiz the 15th October 1498.

---

[1] Montagu's Life of Bacon, Works, vol. xvi. parts 1 and 2, 1834. Edinburgh Review, vol. lxv. No. 132. article I. Stewart and ayfair, in the Preliminary Dissertations to this Encyclopædia. Napier on the Scope and Influence of the Philosophical Writings of Lord con; in the Transactions of the Royal Society of Edinburgh, vol. viii. part 2, 1818.

The year following he revisited America, and after sailing along the coast under the tropics, he returned by the island of St. Domingo, where Ojeda had some encounters with the Europeans who six years before had come to the island with Columbus. The fleet then steered northwards and discovered several islands, which Amerigo, by a poetical exaggeration, raised to the number of a thousand. In 1501 he entered the service of Emmanuel, king of Portugal, and again visited America, sailing along the coast of Brazil to Patagonia. He made a fourth voyage to America in 1503, with the view of attempting the discovery of a western passage to Malacca; in this, however, he was unsuccessful, and returned with the loss of one of his ships. About this time the vast continent discovered by Columbus began to be called America, from his Latinized name *Americus;* and he lived to enjoy the usurped honour for several years. His death took place in 1516, while he was in the service of Emmanuel, king of Portugal, who caused the remains of his vessels to be preserved in the cathedral of Lisbon, and heaped honours on his family. He left a journal of four of his voyages, which was printed at Paris in Latin, in 1552, and from which translations were afterwards published in the Italian and French languages.

VESTA, in pagan worship, the same with Cybele. See CYBELE.

VESTA the *Younger*, in pagan worship, the goddess of fire, was the daughter of Saturn and Cybele, and the sister of Ceres. She was so much in love with chastity, that on Jupiter's ascending the throne, and offering to grant whatever she asked, she only desired the preservation of her virginity, which she obtained. Vesta was not represented in her temple by any image.

VESTA, one of the lately discovered planets. See ASTRONOMY.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the 5th of the ides of June; that is, on the 9th of the month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge. They were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom was one superior to the rest, and called *vestalis maxima.* The vestals were chosen from six to ten years of age, and obliged to strict continency for thirty years; the first ten of which were employed in learning the ceremonies of religion, the next ten in the performance of them, and the last ten in teaching them to the younger vestals. The habit of the vestals consisted of a head-dress, called *infula*, which sat close to the head, and from whence hung certain laces called *vitta;* a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBULE, in *Architecture*, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a certain number of persons chosen to have the governmen of the parish, make rates, and take the account of church wardens, &c.

VESUVIUS, a celebrated volcano of Italy, six miles eas from the city of Naples. This mountain has two tops; one of which only goes by the name of *Vesuvius*, the other being now called *Somma;* but Sir William Hamilton is o opinion, that the latter is what the ancients called *Vesuvius* The perpendicular height of Vesuvius is only 3700 feet though the ascent from the foot to the top is three Italian miles. One side of the mountain is well cultivated and fertile, producing great plenty of vines, but the south and west sides are entirely covered with cinders and ashes while a sulphureous smoke constantly issues from the top sometimes attended with the most violent explosions o stones, the emission of great streams of lava, and all the other attendants of a most formidable volcano. The firs of these eruptions recorded in history took place in the yea 79; at which time the two cities of Pompeii and Herculaneum were entirely buried under the stones and ashe thrown out. Incredible mischief was also done to the neighbouring country, and numbers of people lost thei lives, among whom was the elder Pliny.

It is the opinion of the best judges, however, that thi eruption was by no means the first that had ever happened The very streets of those cities which were at that tim overwhelmed, are said to be partly paved with lava. Sinc that time thirty different eruptions have been recorded some of which have been extremely violent. In the yea 1538, a mountain, three miles in circumference, and a quarter of a mile in perpendicular height, was thrown up in th course of one night.

The first great eruption taken notice of by Sir William Hamilton was that of 1767, which, though very violent, wa mild in comparison with that of 1538. From this tim Vesuvius never ceased for ten years to send forth smoke nor were there many months in which it did not throw out stones, scoriæ, and cinders; which, increasing t a certain degree, were usually followed by lava; so tha from the year 1767 to 1779 there were nine eruptions some of them very considerable. In the month of August that year, an eruption took place, which, for its extraordinary and terrible appearance, has been generally reckoned among the most remarkable of any recorded concerning this or any other volcano. We cannot, however afford room for any description of it here, or of the various eruptions which have since taken place. See GEOLOGY.

VETERINARY SCIENCE.

THE knowledge and the enlightened treatment of the diseases of domestic animals have, in this country, been elevated to the rank of a science only within the last fifty years. Previously to that time, the art of Farriery consisted in the traditionary lore of the worker in iron, *faber ferrarius*, or smith; and in later times, in the professional skill of a few medical practitioners, who were not, however, sufficiently careful to ascertain the many striking differences which exist between the economy of man, and that of the lower animals. The modern term *veterinary*, derives its origin from the Latin *veterinarius*, an adjective denoting relation to beasts of burden. The same word, used as a substantive, signifies a person who has the care of such beasts. The etymology is, however, involved in considerable obscurity The first veterinary school was founded at Lyons in the year 1761, and another was founded at Alfort, near Paris, in 1766. In the year 1792 the Veterinary College of London was established, and it is to this date that the origin of the science in this country may be correctly assigned. More recently a school of veterinary medicine has been founded n the northern metropolis, under the patronage of the Highland and Agricultural Society, so that the art no oubt will continue, as it lately has done, to make steady nd rapid progress.

The science of veterinary medicine must evidently be ased upon a minute and accurate knowledge of the structure and functions of all those animals which may require s aid, as also of the disorders and accidents to which these e exposed, and the various resources, whether natural or tificial, available for their cure. This opens a wide eld, and shows the value of the light which may be orrowed from collateral sciences. From the paramount mportance which man attaches to every thing which concerns himself, human anatomy, and the sciences of medicine nd surgery, have from time immemorial been prosecuted ith the keenest assiduity. Natural history has long ad its numerous and enthusiastic votaries, and hence so much knowledge on the subjects of comparative anatomy nd physiology. If there be analogies of structure between man, and "the humbler partners of his mortal pilgrimage," hen both are in health and strength, sure we are these are ot fewer or less striking, when they are labouring under he many ills to which they alike are heirs. From these arious sciences much valuable information has undoubtedly been gleaned in aid of that which is now to engage ur attention; and we cannot too strongly impress upon he veterinary student, that before he is competent to learn he art of healing, he must have an accurate knowledge f the anatomical structure, and the physiology, of the omestic animals. For the acquisition of this primary ranch of the science, we must refer him to the several rticles concerning them in our previous volumes,[1] and to he approved elementary treatises, of which a list is supplied t the close of this article; confining ourselves to such general allusions concerning these matters, as may be unavoidable in the course of the following observations. Our space being very limited, we must endeavour to instruct, more by a useful classification and nomenclature, and the exposition of correct principles, than by entering into matters of detail.

mma

We commence with a few general remarks on INFLAMMATION. When a part, like the white of the eye, becomes red, hot, pained, and swollen, it is said to be in a state of inflammation, and the symptoms are chiefly ascribed to a morbid state of the blood-vessels, there being an increased determination of blood to the part. This disease may be excited in any part of the surface, by a wound or other irritation; and there is no internal organ which is not liable to attack, and often without any very apparent cause. Hence inflammation, in one form or other, is the most common disorder which is encountered, and withal the most fatal. It is most apt to occur where there is a plethora, or general fulness from over-feeding and insufficient exercise; and is excited by over-exertion, by sudden changes of temperature, and by checked perspiration. It has several modes of termination, of which resolution, or the gradual subsidence of the disease, is the most favourable: another mode is effusion of the serum, or watery portion of the blood, where temporary swellings and dropsies are occasioned; or of coagulable lymph, by which morbid adhesions and growths are produced; another termination is suppuration, or the formation of matter, and finally, there is gangrene or mortification. It is sometimes very rapid in its progress, or *acute*, at others it is slower, and is then styled *chronic*. When the inflammation is local, limited in extent, and somewhat external, warm *fomentations*,[2] or *poultices*,[3] which are a kind of fomentations, or cold applications,[4] may each be applied with advantage according to circumstances. Fomentations open the pores of the skin, promote perspiration, and so lessen swelling and tension, and assuage pain and inflammation; while cold applications promote evaporation, subdue inordinate action, and so assist in restoring health. When the symptoms are acute, and the disease spreads, as it is prone to do, the whole frame more or less participates, and symptomatic fever is the result.

Fever, symptomatic.

Concerning the occurrence, in the domestic animals, of SYMPTOMATIC FEVER, produced by accident and disease, as injury of the foot, or inflammation of the eye, there can be no doubt whatever. This complaint corresponds in every respect, except its exciting cause, with the SIMPLE INFLAMMATORY FEVER, a disease whose existence has been denied by some, but on very insufficient grounds. "In so plain a point of practice as this," says Mr Percivall, "we might as well attempt to deny the existence of inflammation in horses as of fever." Its first symptoms, which may not be always easily detected, are dulness and heaviness, hanging down the head, and disinclination to move. This will probably be followed by chilliness, marked by a staring coat, coldness of the surface and extremities, and sometimes an actual rigor or shivering fit: to this succeeds a warm skin, a hot and dry mouth, redness of the eyes and lining membrane of the nose, a quick, full, and hard pulse,[5] rapid respiration, with apparent labour rather than pain; there is also loss of appetite, costiveness, high-coloured and diminished flow of urine, and increased sensibility. The causes most frequently apparent are over-exertion, sudden increase of temperature, and plethora; they are often obscure. The disease appears sometimes as an epidemic, as stated by Mr Gibson: "I have frequently had several cases of this fever at the same time, and in different places, where no visible cause could be assigned for it." The indications of cure are the same as in symptomatic fever, venesection usually not requiring to be carried far, or often repeated. Returning to symptomatic fever, we remark, that the treatment consists in the vigorous employment of what is called the ANTIPHLOGISTIC REGIMEN. Of this the most important item is *blood-letting*, general and local, the former being infinitely the most important.[6] With this must be combined purging, or rather the administration of laxatives, with the object of removing irritation, and diminish-

Simple inflammatory.

---

[1] Anatomy, and Comparative Anatomy, in vol. ii. and iii.; Physiology, vol. xvii.; Horse, vol. xi.

[2] Clean water is the best FOMENTATION. It should be as hot as the hand can bear it, yet not hot enough to pain the animal. In fomenting the horse, the groom rarely has enough of water, and he does not continue the bathing long enough to do any good. If the leg is to be fomented, get a pailful of water as hot as the hand can bear it; put the horse's foot into it, and with a large spunge lave the water well above the affected part, and keep it constantly running down the whole limb. Foment for about half an hour, and keep the water hot by adding more.

[3] POULTICES should be formed of those materials which best maintain heat and moisture, and they should be applied as warm as possible, and can be safely borne. They are usually made of bran mash, turnips, or oatmeal porridge. Linseed meal alone makes the best of poultices, and some of it should always be added to the other ingredients. Wet bandages act as poultices.

[4] Of COOLING LOTIONS cold water is the menstruum. It may be made colder by the introduction of a little salt or ice; sal ammoniac and vinegar may be added for the same purpose. The object is to reduce heat, and promote evaporation. The addition of a little spirits is made with this object.

[5] Of the horse, the natural PULSE is from 35 to 45 beats in the minute; under fever it rises to 80, 90, and 100. The most convenient spot to examine it is at the edge of the lower jaw, a little before the angle, where the maxillary comes from the neck, to be distributed over the face. The pulse is one of the most important indications in all serious disorders.

[6] BLEEDING. In the horse, and cattle, sheep, and dog, bleeding, from its greater facility and rapidity, is best performed in the jugular or neck vein, though it may also be satisfactorily performed in the *plate* and *saphena* veins, the former coming from the inside of the arm,

ing the watery part of the blood.[1] Large warm injections should at once be resorted to, and they are often of signal benefit:[2] the food must be regulated and restricted,[3] and the temperature attended to. *Diaphoretics* may often be employed with advantage,[4] and associated with them smart friction over the whole body, by wisping and hand-rubbing.[5] When the inflammation is local, counter-irritation should be employed; in acute cases most effectually by blisters.[6]

As there are no good grounds for denying the existence of Simple Fever, so we are persuaded there are as few for denying the occasional visitation of LOW FEVER, however much it may be generally overlooked. It has been confounded with other grave complaints, but was very generally the essential disease in those murrains which were so common in former days, and which acquired other and most unsatisfactory appellations. It is well observed by

---

and running up directly in front of it to the jugular; the latter, or thigh vein, running across the inside of that limb. Either the fleam or lancet may be used. When blood is to be drawn, the animal is blindfolded on the side to be operated upon, and the head held to the other side; the hair is smoothed along the course of the vein by the moistened finger, the point selected being about two inches below the angle of the jaw. The progress of the blood towards the heart is to be obstructed, and the vein thus made sufficiently permanent and tense. A large-bladed fleam, and a good-sized lancet are preferable, as the benefit of the operation is much increased by the rapidity with which the blood is drawn. From 8 to 12 pints is a moderate bleeding for the horse and ox, regulated in some degree by the size. From 12 to 16 or even 20 pints is a large one; and sometimes, in skilful hands, it is expedient to bleed till fainting is induced, and the animal drops down under the operation. The vessel in which the blood is received should be such that the quantity can readily be ascertained. When this is sufficient, the edges of the wound are to be brought accurately together, and kept so, by a small sharp pin being passed through them, and retained by a little tow. It is of importance, in closing the wound, to see it is quite close, and that no hairs or other foreign bodies interpose. For a time the head should be tied up, and care taken that the horse does not injure the part.

LOCAL BLEEDING may be performed in the *palatine* vein, in a line backwards between the middle or central cutting tooth and the second, and a little more than an inch within the teeth. The division is made by means of the bistoury, and the artery as well as the vein is sometimes wounded; hemorrhage, however, may here he readily commanded. In the *foot* it may be performed at the union of the crust and sole, by cutting down with a searcher or fine drawing knife. For stopping it, a pledgit of tow may be applied, and the shoe tacked over it.

[1] PHYSICING, which in stable language is the term used for purging, is employed for improving the condition when in indifferent health, and as a remedy for disease. The medicines chiefly used are, for *Horses*, Barbadoes aloes, dose from 3 to 9 drachms, croton *bean*, from a scruple to half a drachm, or *cake*, from half a drachm to a drachm, to which may be occasionally added, calomel, from one drachm to a drachm and a half; for *Cattle*, aloes, in a dose somewhat larger than for the horse, Epsom salts (very uncertain in horses), or common salt, dose from a pound to a pound and a half, with some stimulus, as ginger, anise, or carraway seed; also Linseed oil, dose 1 pound, and croton oil, 15 to 20 drops, or the bean and cake, the same as in the horse. For *Dogs* aloes prove uncertain, and jalap, dose 1 drachm, is far surer, and better when combined with calomel, 2 grains; croton oil, dose 2 drops, also valuable, and the bean 5 grains, and syrup of buckthorn, dose an ounce. These, it will be observed, are average doses for full-grown animals; in the young and small, they should be less, in the large they may require to be greater; but much injury has often been done by too large doses, too frequently repeated. To the Horse, physic is usually administered in the form of a bolus, or *ball*, to Cattle by drinking or *drenching*, though for both either way may be employed. A ball is conveniently made of linseed meal, molasses, and the active ingredient, whether purgative, diuretic, or cordial; it should be softish, and about the size of a pullet's egg. In administering it, the operator stands before the horse, which is generally unbound, and turned with its head out of the stall, with a halter on it. An assistant stands on the left side, to steady the horse's head, and keep it from rising too high; sometimes he holds the mouth, and grooms generally need such aid. The operator seizes the horse's tongue in his left hand, draws it a little out, and to one side, and places his little finger fast upon the under jaw; with his right hand he carries the ball smartly along the roof of the mouth, and leaves it at the root of the tongue: the mouth is closed, and the head held, till the ball is seen descending the gullet on the left side. When loath to swallow, a little water may he offered, and it will carry the ball before it. A hot, troublesome horse should be sent at once to a veterinary surgeon. Instruments should if possible be avoided; and adding croton farina to the mash often answers perfectly well. *Drenches*, on the whole, operate more speedily than balls, and are sometimes necessary. As many horses and cattle have been killed by the practice, (some of the fluid being forced into the lungs,) though heedlessly regarded in stables, and even in books, we advise that becoming caution should be employed, that no unnecessary force be used, that they never be given by the nostrils, and especially that if the slightest irritation is occasioned in the windpipe, the animal shall immediately he set at liberty, that by coughing he may free himself of the offending matter. Physic is given to a dog by pouring it over his throat with a spoon, or he may be made to bolt it in a thin slice of meat; the syrup of buckthorn he will often lick spontaneously.

The horse must undergo *preparation for physic*, which is done by gently relaxing the bowels. During the day previous, his food should be restricted to bran mashes, a quarter of a peck being sufficient for a feed, and this, with his drink, should be given warm; corn should be withheld, and hay restricted. He may have walking or trotting exercise morning and evening. The physic is given on an empty stomach, early in the morning; immediately afterwards a bran-mash is given; that over, the horse goes to exercise, for perhaps an hour, and is watered when he returns. The water should be as warm as he will take it, and he should have as much as he pleases throughout the day; bran mash should be given as often as corn usually is, and better warm than cold; if both are refused, bran may be tried, but no corn, and but little hay. Sometimes gentle exercise may be given in the afternoon, and also next day. The physic usually begins to operate next morning, though it rarely takes effect in twelve hours, frequently not for thirty. When the physic begins to operate, the horse should stand in the stable till it *setts*, which may be in twelve hours.

[2] INJECTIONS, though easily administered by means of the old ox bladder and pipe, are still more conveniently given with a syringe. For laxative clysters for the horse or cow, from a gallon to 12 pints of warm water, or gruel, at the temperature of 96°, with a couple of handfulls of salt, or two ounces of soft soap, prove most useful. Stronger ones may be obtained, by adding a few ounces of aloes to the mixture. In cases of diarrhœa, or over-purging, the injection should consist of a few pints of warm gruel, to which is added an ounce of catechu electuary, or from half a drachm to a drachm of powdered opium. The only art in administering a clyster, where, however, there is often bungling, and even injury, by wounding the rectum, is to avoid frightening the animal, anointing the pipe well, and gently insinuating it, before the fluid is forced up.

[3] In general, bran mashes, carrots, green meat, and hay, form the sick horse's diet, gruel and tepid water his drink.

[4] DIAPHORETICS are those medicines which have a tendency to produce perspiration and sweating. Some of these are of a hot and stimulating quality, and these must be avoided in febrile disorders. The others are neither very numerous nor powerful. Emetic tartar, dose from one drachm to two drachms, and fox-glove in powder, dose one drachm, are the most powerful. Nitre, in doses of 3 or 4 drachms, is often combined with these. Sulphur, in doses of 4 or 5 ounces, is sometimes useful.

[5] When two men are employed on each side, the effect and benefit are often surprising.

[6] BLISTERING PLASTERS are never applied to horses. An ointment is always used, of which rather more than half is well rubbed into the part to be blistered, while the remainder is thinly and equally spread over the part that has been rubbed. When there is any danger of the ointment running, and acting upon places that should not be blistered, they must be covered with a stiff ointment made of hog's lard and bee's wax, or kept wet with a little water. The bedding must be removed when the leg is blistered, aud to prevent the horse slipping, the stones may be covered with a little short litter or saw-dust. The horse's head must be secured in such a way that he cannot reach the blister with his teeth. Put him into a narrow stall, and tie his head firmly to the rack. When the blister has become quite dry, the head may be freed, and the horse let down. Sometimes it remains itchy, and the horse rubs it; in that case, he must be tied up again. If be get very tired, and threaten to go down on his haunches, put the beads on his neck, let go the head, and give a good bed. When the blister is quite dry, put some sweet oil upon it, and repeat it every second day. Give time, and no work, otherwise the horse may be blemished by the process.

eminent pathologist, that as local inflammation gives rise constitutional febrile symptoms, so idiopathic fevers of kinds, in their turn, often give rise to, or at least are companied by local inflammatory symptoms. The old riers mistook these local symptoms for the fever which oduced them, and we fear the error is sometimes comtted in our own days. The characteristic symptoms are neral disturbance of the circulation, and feeble, rapid lse, weakness, prostration of strength, determination of od to particular, but, in different instances and epidecs, very different parts, producing pain, and manifesting tendency to inflammation, but of a degenerate kind, so it the very texture of the tissue becomes disorganised. ie progress of the disease is often rapid, and the result y fatal. In some cases, the lungs or heart are attacked, others the liver, bowels, or even some external part of body. This we believe to be the true history of such eases as the *quarter-evil*, the *black-quarter*, the *joint-on*, and various *braxies*, which figure so conspicuously in older works, and whose ravages were attended with h fatal consequences to the agriculturist. In some wellertained instances, nineteen individuals have died out of ry score which has been attacked. To the possible rerence of such complaints, the veterinarian should not it his eye; and, in actual practice, we have witnessed schief where these circumstances have been disregarded, l where bleeding, though not excessive, has been pushed far, with the object of relieving the local complaint, to considerable sacrifice of life. In these cases, we have anged the treatment, administered wine and other corls, instead of debilitating remedies, and thus have arted the progress of mortality.

ogy.

In the study of the veterinary art, the ground-work is TEOLOGY, inasmuch as it relates to the most fixed and ble part of the frame, and so becomes the guide and ditory to the relations and actions of all other parts. In ordance with this fact, we shall first direct attention the Osseous system.

es of

DISEASES *of* BONES are not common, and the only ones shall mention are *Exostosis* and *Necrosis*, under which *ries*, or ulceration, and *Anchylosis*, may be included.

sis.

OSTOSIS is an osseous tumour, originating from a bone, in ich the periosteum is always necessarily involved, there ng thickening of this membrane, and deposition of osseous tter by it, in many cases, not less than by the bone it-f. It may generally be the result of some local iny, though unquestionably it may occur from other causes. ere is no bone which it may not attack; and an exosto-as large as a child's head, has been seen on some of bones. The attending pain seems to vary, and to be atly dependent upon the extent to which the circumjat parts are involved, as does also the degree of lameness nay produce. With a few exceptions, the disease does often force itself upon notice. The appropriate remevery uniform in its beneficial results, is counter-irrita-n, by frequent, and if necessary, smart blistering, firing, setons. In some cases, it may finally call for excision. e exceptions just alluded to, are the diseases known unthe names of *bone-spavin*, *splint*, and *ring-bone*, which doubt afford specimens of the disease. But it is morer true, that, in these instances, other tissues than those ned are implicated, and often primarily; so that we shall

is.

tpone their consideration. NECROSIS is the death, more less extensive, of the whole or part of a bone. An effort nade by nature to throw it off from the frame, by exfolia-n; and it is often wonderful to observe what is effected in way. The disease is not, however, often witnessed in lower animals, so we need not dwell longer upon it. ANYLOSIS, or a bony union of parts of a joint which were urally free, and played on each other, often occurs, the result of long-continued irritation and inflammation of the parts implicated.

Fractures.

FRACTURES are not uncommon among domestic animals; although, from the frequent attendant violence, many of them are beyond the reach of art. Thus is it generally with *fracture of the skull*. Sometimes the ridge of the *orbit*, at its outer and upper part, is fractured by falls, and more frequently by blows: the detached portion may be replaced, and retained by stitching the skin, and bandages. The spinal processes of the vertebræ are sometimes fractured, and *caries* of these parts occurs from injuries of the saddle. The ribs, too, are subject to fracture, and the sacrum, from falling backwards, when paralysis of the tail occurs. The extremities, however, are most liable to this accident, including the femur and tibia, the scapula, humerus, elbow, fore-arm, cannons, pasterns, and coffins. Fracture of the leg occurs on the road or street, the rider or driver not knowing whether the accident has occurred in the fall, after it, or in trying to avoid it. It may be that the fracture is produced by a blow from the opposite foot. When the end of the bone protrudes through the integuments, the fracture is called *compound*, and the prospect of a successful issue is then greatly diminished. It is a great error to suppose that a horse's bone, once broken, cannot unite; it does so as readily as in man. When the attempt is not made, it is on account of the cost and trouble. When an animal is highly valued, the cure may be wisely undertaken, and successfully accomplished, by the application of splints and bandages, the sufferer not being slung. In sheep, fractures heal with great facility; and also in the dog.

Muscular system.

On the MYOLOGY, or muscular system of the lower animals, we shall say but little. It consists chiefly of two parts,—of what constitutes generally the body or belly of the muscles, popularly called flesh; and of shining *tendons*, into which these *muscular fibres* are inserted, forming strong elastic cords, which are fixed into the bones and other parts which are to be moved or compressed. These tendons generally lie over and round the joints, thereby strengthening them. To these must be added the *aponeuroses*, which are tendinous wrappers or binders, of various thickness, which cover various sets of muscles, and occasionally connect them to each other, and to the bones beneath. These constituent parts of the muscular system, and especially the last, are generally esteemed the seat of RHEUMATISM; a disease from which the lower animals are not altogether exempt. It is generally produced by sudden exposure to cold and rain, damp and drought, after being overheated. Sometimes it is more general, accompanied with pain, lameness, and fever: in other cases it is local. One form of the *Chill* of Mr White, resembles *Rheumatic fever* in man. A few hours after violent exercise, especially if the horse has been plunged into a river, or washed freely with cold water, and then placed in a current of air, it may be found almost incapable of moving, and can scarcely be led out for examination without difficulty, and this by metastasis, may change into *acute founder*. With this there is quick pulse and rapid breathing. The pain may be generally diffused, or local. Sometimes it is confined to the muscles of the chest, when it forms the *chest-founder* of Gibson, and many farriers. The term *anticor* is sometimes applied to this disease affecting the breast, but it is also applied to any uneasiness or swelling of the part. The disease often falls upon the loins in oxen, constituting the *chine-felon* of older writers, and arising from the same causes as those mentioned above. Sometimes it shews itself at one or more of the joints, forming the *joint-felon*. We have witnessed acute rheumatism in the elbow and stifle, though rarely; but frequently in the fetlocks, after catarrhal affections. The treatment in all these com-

Rheumatism.

plaints consists in bleeding, moderate purging, with fomentations and embrocations to the swellings. The disorder called the *founder* in dogs, is this disease, usually produced by the same class of causes, and requiring the same kind of remedies. In addition to bleeding and purging, hot baths, and a dry and comfortable kennel, with small doses of colchicum and antimony, are the most successful remedies, followed by regular exercise.

Joints.

Besides the tendons already mentioned, and the accurate fitting of the bones into one another, having their extremities covered with *cartilage*, a substance in firmness and elasticity approximating to caoutchouc, the **JOINTS** are greatly strengthened by what are properly called *ligaments*, and which consist of strong tendinous cords, passing from bone to bone, and most firmly binding them together. Internal to the cartilages, and lining the cavity of the joint, is a fine vascular membrane, designated the *synovial*, whose office is to secrete the joint-oil: and to finish these details, we have only to add one other fact, namely, that wherever friction occurs, as of a tendon upon a bone, there is found what is called a *bursa*, which is nothing else than a fine bag, which secretes a lubricating fluid, so facilitating the motion. All these parts, it will be understood, enter directly into the formation of the joints; and when these exquisite structures are considered, and their extreme liability to accidents, it will at once be perceived how complicated and important these injuries and diseases must necessarily be. We now return to the diseases of the bones already named, to which we shall add those of the other parts just mentioned.

Bone spavin

After the exposition already given of the pathology of exostosis, the somewhat complicated examples of it, to which we now proceed, will not occupy us long; and the description of one will nearly serve for the others. **BONE SPAVIN** occurs in the lower part of the hock. It is usually observed as a small hard tumor, at the top of the shank bone, and of the inner splint bone, near the lower wedge bones. It seems to be produced from stress or over-work, occurring especially in young horses, and at first is commonly attended with pain, occasioning considerable lameness. The ligaments and cartilages have probably been injured; the periosteum and bone inflame, swell, and throw out ossific matter, and, unless care be taken, the disease spreads to the wedge bones, and to the astragulus, thereby involving the hinge-joint of the hock, a result most anxiously to be avoided. The treatment, which should commence early, is mainly counter-irritation, by repeated smart blistering, firing, setons, punching, and long rest and ease. Under the treatment specified, many complete cures have been effected, and with no return of the disease. From the want, however, of sufficiently active treatment, and of due patience, only partial relief is very often obtained. The horse is rendered unfit for quick and hard work, and remains spavined for life. The circumstance of the lameness diminishing in the chronic state, under exercise, is explained by the principal seat of motion, between the astragulus and tibia, being free, and the stiffness and pain being felt chiefly in some less important parts of the articulation.

The splint.

The **SPLINT** or *splent* now requires little more for its elucidation than being defined. It acquires its name from its seat, occurring always on one of the splint bones of the leg. A tumor, which feels hard, appears between the knee and fetlock, and generally upon the inside of the leg. Its nature, causes, symptoms, and cure, entirely correspond with those of the last-named disease. The deformity often appears in a chronic state, gives no great trouble, and finally may disappear.

Ringbone.

RINGBONE has acquired its name from its form, usually shewing itself just above the coronet, where it is an ossification of the lateral cartilages, from compression and irritation. Though generally commencing at this point, it is apt to spread, producing anchylosis between the large and small pastern bones. It occurs more frequently on the hind than the fore feet. If sufficient time be not allowed for the active use of means, the whole joint may be involved, and become useless.

ABSCESS, the result of inflammation, more or less acute, is a circumscribed swelling, containing matter in the surrounding cellular membrane, which forms a cyst for containing it, the matter or pus being a product of the inflammation. This pus generally must procure vent for itself, and, as a general principle, in that direction where the resistance is the least. Thus it usually comes to the surface. Often, however, it does not; the abscess bursting in another direction, the matter escapes, and a **SINUS**, fistula, or **PIPE**, so designated by farriers, occurs. These sinuses burrow especially among the fasciæ, tendons, joints, and other parts lately alluded to. Abscess may occur in any part of the body; and the object of art ever is, to expedite its formation, and to afford a free and speedy evacuation, especially when from its locality, there is risk of sinus. When sinuses form, they must be freely opened; sometimes by counter-opening to that extent, that the matter shall have the most direct and safest exit. In this connection two complaints require mention. **POLL-EVIL** is a name derived from its proximity to the head. The cranium is sustained on the neck by the help of *ligamentum nuchæ*, or pack-wax, a broad and strong ligament, altogether of a peculiar nature. It not unfrequently happens that, from a horse's raising his head violently against the manger, or bruising it with the halter, or from cruel blows of brutal stablemen or carters, an injury is inflicted. T a certain extent it may be superficial; but in addition from the contusion of the inner surface of the ligament or the bones, inflammation is often excited in the soft part beneath. Hence the secretion of pus, which could never work its way through the pack-wax; and hence i burrows deep, and in different directions, till serious injury is done far and near, not sparing, sometimes, the bon processes. So soon as the disease is discovered, the treatment is plain, and if judicious, effectual. The probe mus instruct, and openings and counter-openings may be mad freely, but with discretion; and the sinuses, wholly or partially freed, may speedily, by means of stimulants, be induced to assume a healthy action. **FISTULA OF THE WITHERS** from the pressure and irritation of the saddle, forms anothe instance in which these sinuses are apt to run deep, an produce much mischief. Hence all injury from this caus requires watching. By pressure we may ascertain the earliest formation of pus; and the abscess should be opened After sinuses are formed, the principle of treatment is th same as just specified. Tents, or dossils of lint, put with in the lips of the wound, may sometimes be required.

To the **BURSA**, so generally spread over the body, w have already made allusion; and in turning to their diseased condition we may affirm that this arises almos solely from an increased effusion into their cavity, produced by a strain of the tendon passing over them, c from increased friction in over-exertion, whereby the become enlarged, tense, painful in themselves, and sti more by the irritation they produce in the neighbourin parts. Sometimes the swelling is enormous, and it matter of surprise there is comparatively so little local an constitutional disturbance. These swellings are popularly called **WINDGALLS**—*Ganglions* in man. Small windgalls may long exist without apparent injury, but they a always unseemly; and when fresh we should endeavour t remove them. Cold evaporating lotions are sometime tried; but we believe smart counter-irritation, by stron and repeated blisters, is much more likely to be useful. I obstinate cases firing is much practised; and though we believe that, in this and other complaints, this painful remed

s been, and still is, much abused, yet, administered dis-
etly, it is too valuable a remedy to be discarded. If the
ng does not succeed, we advise puncturing the cyst, ap-
ing compress and bandage, and healing the external wound,
ere there is any difficulty, with the help of the actual cau-
y.[1] This being the nature and the treatment of windgalls
erally, we can speedily dismiss those which, from pecu-
ity of position and importance, have figured as distinct
l peculiar diseases. **Bog-Spavin**, sometimes called
ood-Spavin, occurs in nearly the same position as
e-spavin, but is much softer in its texture, and elas-
Its causes are the same as those already mentioned.
e circumscribed tumor obstructs the return of the blood
m the neighbouring veins, which consequently swell;
ce the name **Blood-Spavin**, and hence the unwar-
table practice of removing a part of the vein. This is
erious disease, though the symptoms are not so acute as
bone-spavin; the lameness is less, though it is obstinate,
l constitutes unsoundness. On the treatment we have
thing to add. **Capped Hock** is named from its position,
back projecting point of the joint. It is usually pro-
ced by blows, often inflicted by the horse itself, by kick-
in harness, or in the stable. If not speedily dissi-
ted, the tumor is apt to become callous and obstinate.
e **Curb** is another enlargement at the back of the hock,
t three or four inches under its projecting point. The
nplaint is produced by an injury of the ligament which
nects the os calcis with the metatarsal bone, and consists
a thickening of the ligament and cellular membrane. It
curs from a sudden sprain, in a race, an extraordinary leap,
severe gallop over heavy ground. The swelling is not
eat, but at first the complaint is usually attended with
neness. Some horses are termed *curby-hocked*, implying
t they labour under a species of malformation, in conse-
ence of which the ligament in question is more liable to be
ured than in other hocks. **Windgalls** are very common
ove the fetlock. **Thorough-Pin**, a swelling both on
out and inside of the hock, is an affection of the bursa
the back part of the joint, with an effusion of the lu-
icating fluid. If the tumor on one side be pressed, the
id is forced into that of the other side; hence the name.
e symptoms arise either from the bursa, surrounding
perforans tendon, passing round the back part of the
ck, being disturbed, or from the capsular ligament itself
ing involved.

Synovial membranes

At elbow.

Broken knee.

Exposed knee joint.

Affections of the Synovial Membranes, so serious in their nature, are almost always the consequence of external injury. When the joints are laid open, especially the larger ones, the danger is great from the inflammatory fever, and the result is often fatal. The opening is sometimes witnessed in the *stifle*, *hock*, *elbow*, and *fetlocks*, but most frequently in the fore *knee*. In the former of these joints it is generally the result of puncture, either accidentally or through brutal usage; the swelling is rapid and extensive, and the attending inflammation most hazardous. The opening into the knee joint is the result of coming down, with severe **Broken Knee**. Under this term is included the slightest division of the skin, as well as the most formidable; and here no injury is trifling. The worst should at once be ascertained by accurate examination. If slight and superficial, the wound may be bathed twice or thrice a-day with Goulard's lotion; swelling and inflammation require repeated poultices; any tendency to proud flesh must be repressed with burnt alum, or blue stone. The appearance of synovia at once demonstrates the nature of the accident; and the limb must then be moved as little as possible, as the rubbing of the ends of the bones on each other is most injurious. The great object here, as in the case of the other joints, is to endeavour to close the orifice, and if possible to anticipate inflammation and fever; and unless this can be effected the animal must be destroyed. By the careful application of plaster, sometimes stitching, applying paste or flour, by skilful bandaging, and complete rest, the puncture has been, and may be healed at once. For the same object white vitriol is applied, and the cautery is often useful. The synovial membrane itself is not to be cauterised, but the superficial parts. If the first application has not been successful in the course of a few days, a second may be tried; and five or six applications have at last rewarded the practitioner's skill.

Sprains.

A **Sprain**, or *strain*, is violence inflicted, with extension, often rupture and displacement, upon the soft parts of a joint, including cellular membrane, tendons, ligaments, and all other parts forming the articulation. The dislocation or disruption may be complete, or it may be a mere bruise or stress; and innumerable are the shades of difference between these extremes. Effusion of the fluids is an attending consequence. Parts of vital importance, as in the neck or back, may be implicated, and the accident be immediately fatal or wholly irremediable; on the contrary, they

---

As it is necessary to explain how this may be safely accomplished, we shall say a few words on the proper mode of securing animals.
itching. A *twitch* is an instrument composed of a noose of cord, attached to the end of a stick; and twitching consists in fixing the
se on the upper lip of the horse, and twisting it rather tightly. From the great pain it can be made to produce it exercises great con-
l over the animal, and makes it stand quiet. The matter is very simple, and, when required, can be applied in the field as well as in
stable. **Casting** is the term used for throwing down a horse or bullock, and so keeping it. In the former animal this is done by
ans of *hobbles*, strong straps and cords particularly arranged, which are first attached to the feet and then suddenly drawn together, so that
animal must fall, the fall being regulated by one man at the head and another at the haunch. Even when most skilfully performed,
m the act of falling and the struggles after it, many accidents have occurred to man and horse. In the case of the ox you take a long
e, double it, and tie a knot in the middle about a yard from the end, so as to leave a noose of sufficient size to go round the bullock's
k; which being put on, the two ends are to be brought between the fore legs, and round the hind pasterns, then back again and through
noose. By standing in front of the animal, and drawing up the ropes quickly, so that the hind legs are drawn towards the chest, it is
ily thrown down; while in this situation the ropes are to be secured, and any operation may be safely performed. The veterinary sur-
n also employs the *side-lines*, *barnacles*, and *trevis*, so much used on the continent; for the particulars concerning which we must re-
to the works named at the end of the article.

In **Firing**, or applying the cautery, casting is a frequent preliminary. The part should previously have been shaven or the hair clipped as
rt as possible. The operation consists in drawing lines, which had best be parallel, about half an inch asunder, on the affected part
h a red hot iron, with a small smooth rounded edge. No part is in a fit state to be fired when the skin is hot or inflamed, and the skin
uld never be deeply penetrated by the iron. According to the heat of the point, so should be the velocity and lightness of touch, and
rown marking from the singing is all that is required. After the firing the horse must be laid up for three or four days to prevent his
uring the part. If the irritation produced is less than was intended, it may be promoted by means of blistering ointment. When it is
shed to moderate it or heal it, the treatment is the same as after blistering. Counter-irritation is also effected by means of the seton and
rowel. The **Seton** consists of a piece of tape or soft cord passed under a portion of the skin by the seton needle; the ends may be
d together, the cord may be moved every other day from side to side, being previously lubricated with oil of turpentine or blister plas-
. Thus the amount of irritation may be regulated; and the practice is often resorted to for relieving deep-seated and painful affections.
e **Rowel** is only a seton under another form. In applying it an incision is made in the skin to the extent of about an inch, by pinch-
it up and cutting it with a bistoury or rowel scissors. The cellular membrane round the wound is then separated to the extent of
out an inch, so as to admit a dossil of tow, which is better than leather, smeared with digestive ointment. A discharge is soon pro-
ed, which has a tendency to relieve any deep-seated neighbouring morbid action.

Veterinary Science.

may be to that extent only, that with time and care, restoration may be accomplished. They constitute a very serious class of cases. The marked symptoms are pain in the injured parts, and inability of motion, sometimes complete. The treatment is at first rest, a regulation of the local action and constitutional disturbance, according to circumstance, by venesection, general and local, the antiphlogistic regimen, fomentation, bandages, and other soothing remedies; and, when the sprain is of an older date, counter-irritation, friction, and gentle exercise.

Of the neck.

A sprain of the NECK is commonly the result of a violent fall upon the head, as in hunting, or in a steeple-chase. The spinal cord may be severely injured, and, according to the precise situation, there may be instant death, or hopeless paralysis. In other cases, without serious injury of the cord, there is displacement of some of the bones, with a slight twist of the neck and head. In such a case there may be recovery, with permanent distortion. Back. A sprain of the BACK may occur in the field or upon ice. The hind feet slip backward, as in leaping a ditch, and the violent effort the horse makes to recover his footing appears to be the cause of the injury. The bones of the spine may thus be partially separated, or the stress may be so slight as to attract no attention till the horse cools. In aggravated cases art can do nothing; the milder ones must be treated according to the principles already laid down. Shoulder. SPRAIN of the SHOULDER assuredly occurs, though *shoulder-lameness* is often imputed when the disease is totally different; hence the importance of discrimination. It is more frequently produced by a slip or side fall, than by fair and violent exertion. On examination there may be neither heat nor swelling in the part; but there will be unwillingness to move the joint; the animal will extend it and raise the leg as little as possible; there will also be soreness in the articulation on pressure, and a peculiar drawing up of the leg. If there be difficulty in coming to a decision from the symptoms, we must take the limb in hand, and observe if the movements of the shoulder-joint give pain. A mild blister often effects a cure; and the constitution is seldom disturbed. Rest must be secured. Hip-joint. Regarding the sprains of the HIP-JOINT, usually called *whirl-bone*, or *round bone*, our remarks would so much correspond to those just delivered, that we shall not repeat them. The STIFLE-JOINT, and the HOCK are occasionally sprained, and such accidents are marked by swelling of the part, and dragging of the leg. Patella. The PATELLA is sometimes dislocated, and the ligaments torn, when the leg is dragged and powerless. The knee-pan should be reduced by drawing the leg forcibly forwards, pressing the patella into its place. The FETLOCKS and PASTERNS are also subject to sprain, and to be involved in the injury of the *perforating flexor of the foot* and the *suspensary ligament*, which are primarily concerned in Breaking-down. BREAKING-DOWN. Two injuries are described under this name. One is merely a *sprain* of the back-tendons, usually in the fore-leg; it may be so slight as to escape notice till the horse cool, or it may be such as to produce marked lameness from the first. The other, or *true breaking-down*, is said to consist in a *rupture* of the tendons and ligaments: it occurs suddenly, and generally when the horse is at full speed; it rarely happens in both the fore-legs at once. The horse stops instantly, or he falls; on rising he is seen to rest on his fetlocks, the toe turned up, the sole looking forward. Some able writers have denied the possibility of the fracture of the ligament; but the true pathology here regards not one ligament or tendon, but all the parts which form the back parts of the joint. Sometimes they are partially torn. When the fetlock does not wholly come to the ground, the foot, skilfully treated, may become as useful as ever; when both fetlocks come down the horse can seldom be recovered. This accident sometimes leads to a contraction or drawing up of the leg, which ultimately knuckles over at the fetlock. For the relief of this, th
tendons must be cut; an operation proposed twenty year
ago, and now coming into general use.

The human hand has been the subject of much and de
served admiration, and the horse's foot is scarcely less a
object of wonder. It is also a highly vital and complicat
ed organ, essential to the well-being of the animal, an
pre-eminently exposed to injuries. On a minute know
ledge of its structure, and the uses of its various parts, de
pends the successful treatment of its multitudinous and im
portant diseases, which, early and accurately discriminat
ed, may often be speedily remedied, while, mistaken an
neglected, they proceed from bad to worse, till the anim
is good for nothing.

We here say nothing of WEAKNESS OF THE FOOT, whic
is rather an original infirmity, than a distinct diseas
though it leads to many. Animals so formed should neve
be put to severe and heavy work, for which they are wholl
unfit. Neither shall we say much regarding SHOEING;
most important art, on the enlightened and careful practic
of which, much of the horse's welfare depends. The gre
principle is to afford a good and level bearing, while t
nails, in giving sufficient attachment, do not injure t
quick. The bearing is to be supplied only to the crust; a
the toe especially must be kept short. When there is a
tendency in the hoof to contract, the nails in the inn
quarter, which is the weaker, should be placed well forwar
so as to confine the play of the back part of the foot
little as possible. Sometimes the extremities of the hee
are turned up, which is called *calking;* and additional pa
are put to the toe, for the purpose of giving purchase
draught; but these additions are unnecessary for the pr
tection of the foot, and only increase the liability to inju
and disease. It occasionally happens in shoeing, that
nail may injure the tender parts beneath; an accident whic
goes under the name of PRICKING, and which is also caus
by wounds inflicted on the sole, by broken glass, sha
flints, &c. As soon as the tenderness is perceived, t
cause should be most carefully investigated. Hard pressu
near the injury may show that the nail is the cause; wh
the shoe must be removed, and the part freely parc
What is to be apprehended is inflammation and supp
ration, proceeding to sinuses. Where irritation is conside
able, rest, and cold lotions, and a laxative may be prescri
ed; when at all threatening, the foot should be envelop
in warm poultices. The disease somewhat advanced, for
a *whitlow*, which is called PIPES or QUITTOR, in which
find that the sinuses have run deep. It may be in several
rections, mounting up to the coronary ligament, causing s
vere and protracted lameness. The cure may be both pa
ful and tedious, but the principle is clear: free vent m
be procured for the matter, all pressure and irritation m
be removed, the parts must be soothed by poultices, and t
sinuses must be gently stimulated to healthy action, by s
lutions of white or blue vitriol, or corrosive sublimate.
is sometimes recommended to plug up the sinuses wi
strong caustics, to urge them to assume a healthy inste
of a diseased action. The plan may occasionally succee
but the action is violent, and will often aggravate the d
order it is intended to remove. Mild dressings and re
will complete the cure. CORNS are usually the consequen
of the irregular pressure of the shoe on peculiarly form
hoofs. Judging from analogy, these annoyances would
supposed to consist of hard cuticular excrescences pressi
on the tender parts beneath; instead of which, they a
mere bruises, generally produced by the heel of the sh
which, from the extravasated blood, assume a reddish
dark colour. These bruises affecting the sensitive parts b
neath, do not act otherwise than injuries from other caus
They usually occur only in the fore-feet: their site is
most invariably in the inner quarter between the bar a

ust, at the heel. If they advance to mischief, it is pre- ely such as has been described under the head of quittor, d must be treated in a similar way.

These injuries, it will be observed, produce inflammation the internal parts of the foot, which somewhat approxi- ates, but yet is different from, that acute inflammatory af- tion of the parts, which is known under the name of cute Founder, and whose primary seat seems to be e laminæ of the coffin-bone, (hence called *laminitis*,) d the other sensitive parts within the hoof. This disease mes on after great stress and over-exertion, and especial- when, after the feet have been battered, and the animal er-heated and exhausted, it is exposed to cold and damp. is however is not the only cause. We have already en, when treating of rheumatism, that by something like tastasis, the morbid action moderating in the chest, as- ils the parts now under review. Still more curious is the t, that when an animal has gorged himself with dry meat, example at the corn-bin, if he escape a disease of the mach, of which more anon, this same acute founder is an casional consequence. Hence, then, though the disease ay be caused by local injury, yet the constitutional agency ust not be overlooked. The symptoms are such as this ew suggests. They appear more frequently in the fore an the hind feet; they may attack the fore-feet only, or the four. First, there is pain manifested, by a general sinclination to move, fidgetiness, and an unwillingness to row the weight on the inflamed feet. The mischief is ry readily and unequivocally detected, by pushing the imal backwards; if he winces under this, and is still un- lling to move, it is an unerring indication of the existence the disease, whether in its mere local or constitutional anifestation. In violent cases, however, the complaint eaks for itself. The foot on examination is perceived to hot, pain is produced by a slight blow, the neighbouring teries pulsate violently, the animal cannot stand without fficulty, and will ere long drop down from the violence of e agony, sometimes resting his muzzle on the affected ember. With this there is symptomatic fever in its acut- t form. The results of the local inflammation need not detailed, the effusion of serum, and formation of pus be- g substituted for the healthy secretions. The whole crust ay be separated from the sensitive foot, leaving the stump re and exposed; or, if checked, the separation may be rtial, or wholly absent, and there may be no greater mis- ief, than by and by, the appearance of a slight depression, ring upon the crust. The treatment will be anticipat- ; it is the antiphlogistic, with an energy commensurate the violence of the symptoms. The bleeding may be cal, though to this we should not attach peculiar import- ce, further than thereby effecting an opening in the sole, giving vent to matter, and saving the coronet. The oes should be removed. In slight cases, the free appli- tion of cold should, with the constitutional treatment, mmand the symptoms. If the crust has separated, more less, by suppuration, its bearing edge must be removed soon as possible, and the weight thrown on the sole to event pumiced feet; and after this, the hoofs may be re- oduced in a perfect state. **Pumiced Foot** is one of those seases which result from acute founder. In it the sole be- mes flat, or even convex, thereby allowing the central d sensitive parts to press on the ground, to their speedy triment. The complaint appears to arise from a morbid cretion of the laminæ, and also of the sole, whereby the ffin-bone has no adequate support. This is most apt to cur, if the animal is put to work too soon after the in- mmatory attack, and when the sensitive laminæ have t sufficiently recovered their healthy condition, the crust, oreover, being apt to curve towards the toe. Sometimes e previous inflammatory action is so obscure, as not to be tected, and the defect in the horny defence is the only evidence of its previous existence. This disease is most apt to appear in horses with wide feet, much exposed to hard roads and pavement; its progress is usually steady, though slow, and many horses are rendered perfectly useless by it. We should ascribe this in some degree to insufficient remedies being employed for its cure. What is desiderated is time, perfect rest, and improvement of the secretory organs, by stimulating the coronet to a healthy secretion of crust, and chiefly by supporting the sole.

Navicular disease.

Contraction of the Foot. Navicular Disease. Grogginess. Great has been the pains taken by able veterinarians to elucidate the disease known under the above names, concerning the vast importance of which in this country, there is but one opinion. By high authority it has been called "the curse upon all good horse flesh," (though, in passing, we remark it is rather the infliction of man, than of any higher power;) and, coinciding with this, is the statement, that the public have sustained greater loss of valuable horse flesh from the havoc of this disease alone, than from all the catalogue of diseases to which the limbs are liable. Unfortunately, however, there is not more uniformity of sentiment concerning the importance, prevalence, general history, and result of this disease, than there is diversity of opinion concerning its pathology; or rather we should say more accurately, its proximate cause. It is universally agreed that the hoof in its healthy and normal state is roundish, and largely endowed with the property of elasticity. When we attach to it an iron shoe, this natural play is impeded; and that this result of domesticity has much to do with the disease, some way or other, is universally allowed; the complaint being unknown among horses in their natural state, and nearly so in other countries where they are as much esteemed and used as in our own. How then, and to what extent does this shoeing operate? Some contend that the contraction of the crust, thus produced, is the true origin of the evil; that this fetters the sensitive parts within; that the sole becomes externally concave, internally convex; that the soft elastic parts are absorbed; that the frog becomes the rock of danger; the capsular membrane of the navicular joint is injured; in a word, that "the navicular-joint disease is the general seat of the chronic lameness of the foot." Many years ago, the present writer took a part in this controversy, and endeavoured to demonstrate that the primary and permanent disease is established in the synovial capsule, between the tendon and navicular bone, and arises generally from strain and over-extension of the tendon, where it passes under the navicular bone. More recent and able writers have since contended that "the inflammation of the little plates covering the coffin bone, is the most usual cause;" and that a degree of inflammation, inferior to that causing acute founder, produces all the sad results. It would be tedious to mention all the discordant opinions which, with much ingenuity, have been promulgated upon the point; but we still believe that the injury of the synovial capsule of the navicular joint is most generally the primary and proximate cause. though we do not contend it is the only cause. Mr Turner, again, thinks that the hardened frog is the rock on which most valuable horses strike; but he allows it is not the sole one; and so it is with other speculations. Why then appear to differ, when substantially we agree? Not that we are here arguing for concession which will compromise the truth; but we hold, that the united persevering ingenuity of scientific men has fully illustrated the nature of this disease; that it has predisposing causes, such as want of paring, shoeing, and still more, bad shoeing, hereditary tendency of particular breeds, and high condition; for it is a disease not of the agricultural, but of the high-bred horse. In like manner, it has manifest exciting causes, such as strain of the tendon, and over-exertion, pressure on the sole, as from travelling with a stone in the foot; and there is the tight shoe exciting irritation of the foot, which, hot and uneasy in the stable, is aggravated by occasional and violent exercise, until the capsular membrane, tendon, laminæ, cartilage, and bone, one after another, and together, are involved in a degree of subacute and inveterate disorder, which has given too much occasion to all the hard things which have been said against it. The symptoms of the early, and, in a practical point of view, the most important stage of the disease, are a peculiar shifting of the feet, and shortness of the step; whilst a degree of heat is found in the foot, more especially about the heel and coronet. There is a continued pointing, or holding the foot in a relaxed position; dryness of the hoof, throbbing of the pastern arteries, and pain on pressure, in the hollow of the pastern. The other parts of the limb are clean and fine; there is general tenderness of the foot on pressure, with tripping and stumbling; finally, the foot is contracted. In the treatment, all possible attention must be paid to the shoeing; the sole should be thinned, the bars pretty freely removed, and the toe made short. The other predisposing causes must, as far as possible, be removed; and the exciting, especially the overtasking, often so inconsiderately and cruelly, the generous nature of our noble steeds, whose dashing, rapid, and firm action, is so frequent a cause of all the mischief. Finally, the proximate cause must be combated, not by clips on the heels, or screws, or jointed shoes, but according to the principles laid down for the relieving of irritation and inflammation; cooling diet, laxatives, blistering, supplying due moisture to the hoof,[1] and turning out. Time, and skill, and care, may thus do much.

Cutting.

The foot and leg of the horse are liable to various external injuries, some of which are inflicted by the one limb wounding the other. CUTTING, BRUSHING, INTERFERING, are said to take place, when the one foot strikes and wounds the opposite fetlock; and they usually occur in young and timid horses with ill-formed legs. The habit requires either a particular form of shoe, with which the shoeing-smith is familiar, or so putting on the shoe that the crust will project beyond it. A boot is sometimes required. The SPEEDY-CUT is an injury of the same kind, where the leg is struck higher up, and when the horse is going fast. In these cases the leg must be covered with a boot. In the OVERREACH the wound or bruise is produced on the heel of the fore-foot by the hind one in travelling. The TREAD is the same kind of injury upon the coronet of the hind foot, either by the tread of another horse, as often happens in cavalry regiments, or by a false step of the other limb. The Overreach is the consequence only of fast paces. A semicircular wound is made; the skin being raised like a flap, which folds backwards and downwards. The injury is done not by the toe, but by the edge of the inner rim of the shoe. Sometimes a part of the skin is quite scooped out. These injuries should not be disregarded, for if neglected they produce Quittor. All that is usually required is to wash the wound well, put into it a pledgit of tow dipped in Friar's balsam, and bind it up with a bandage. If the cure is not at once effected, and a slough forms, the disease is called a CORE, and requires for its cure only a continuation of the same remedies, with poultices.

Speedy-cut. Overreach. Tread. Core.

One of the functions of the coronary ligament is to secerte the matter answering to the nail in man, which goes to form the crust or external wall of the hoof in animals. When a part of this band has been wounded or injured by disease, it can no longer perform its functions aright, and hence the disease called FALSE-QUARTER. It appears in very different degrees, sometimes forming quite a cleft or fissure, and sometimes exhibiting in the diseased part only a somewhat modified and inferior kind of horn. The secretion is, in short, to different extents deficient and irregular, which exposes to further injury, is accompanied with more or less tenderness, making the part incapable of bearing the pressure of the shoe, and often causing lameness. The primary attention in the treatment must be given to the diseased coronary band, removing as far as possible the cause, by careful paring, protecting and cherishing it, sometimes with digestives, sometimes by blistering. The fissure should generally be filled with some mild ointment, or with tar, as dressing, bound on by a coarse tape, and covered with a coating of pitch or tar. When the animal is kept at work, the shoe should be so applied that the pressure be not imposed on the diseased part. A SAND-CRACK is also a fissure of the crust, and differs principally in this, that it does not necessarily proceed from a previous injury or known disease of the coronary band. It may happen in an instant, from a false step; and hence a horse, though he may spring a sand-crack within an hour after purchase, cannot be returned on that account to the seller. Into this crack, or perpendicular division of the hoof, the sand or dirt enters. It occurs in both fore and hind feet, and in the former usually in the inner quarter, in the latter, in front, the principal stress being there; it arises from dryness and brittleness of the crust; sometimes it does not penetrate through the crust, and then it causes no lameness. It must not, however, on that account be neglected. It should be carefully rasped out, and treated as advised under the last-named disease, the shoe being so modelled as not to press upon the crust under the crack. Firing may be occasionally necessary. When it penetrates to the quick, pain and lameness ensue, and fungous growth may appear, which must be removed by opening out the fissure, and by stimulants or escharotics, after the inflammation has subsided. The sole should be kept sufficiently moist, the hoof occasionally pared, and the horse turned to grass. The crack will, with time, recede from the coronet, till at length it totally disappear.

False quarter.

The THRUSH or *Frush* primarily attacks the frog, and appears to arise from the continued application of moisture, dirt, and other irritating matters, though it is sometimes supposed to owe its origin to a wound of the frog, or a contraction of the hoof, whence it proceeds to the external parts. Horses of all ages, and even the unshod colt, and in all situations, are subject to the disease, and it appears more frequently in the hind feet than the fore. Among its first symptoms is a discharge of offensive matter proceeding from the cleft, and gradually pervading the whole frog. If neglected, the entire foot may become involved. The sooner, therefore, that the primary disease is cured the better; and cleanliness and astringents are the appropriate remedies. After being thoroughly cleaned out, the excavation may be filled with calomel, which generally cures; or with pledgits of tow dipped in warm tar, or some escharotic wash, every night, and retained sometimes during the day. The general health should be attended to, and exercise not neglected. The term SEEDY-TOE has been applied to a chronic form of softening and local irritation, which, beginning between the crust and sole, gradually spreads round the foot. It seems to be aggravated, if it be not sometimes occasioned by mire and gravel insinuating itself into the altered texture of the edge of the sole: sometimes inflammation of the sensitive parts beneath is assigned as the cause. The treatment is the same as that of the complaints with which it is associated.

CANKER is usually a mere extension and aggravated form of the preceding diseases, from want of care and attention, though sometimes it follows other injuries. The nsible frog, instead of secreting horn, produces a fungous owth which pervades the whole sole, and ultimately tends to the entire secreting surface of the foot. It is ost commonly seen in, and is almost peculiar to the heavy eed of cart horse, which is often peculiarly exposed to e exciting causes, and sometimes, it would seem, there is strong hereditary predisposition. Those with white feet e most liable to attack, and the hind feet more than the re. After it has existed for some time, the disease is fficult of cure. The principle on which the cure must be nducted, is the removal of the diseased sole and fungous owths, so giving free vent to the morbid discharge, by eans of the knife and escharotics; lunar caustic, and ustic potash, likewise being often highly useful; and this fected, astringents, escharotics, and pressure are to be nployed. M. Feron regarded tar and sulphuric acid in e proportion of four ounces of the former to two drachms the latter, as a specific. Cleanliness, perseverance, and ne, will effect a cure.

---

[1] Tow, moss, cow dung mixed with clay to give it consistence, and Cherry's felt pads, are the best materials for STOPPING. Clay alone is apt to get too hard, though it may answer for great heavy horses, whose work is slow, and whose heels are raised from the ground by high calkins. Tow and moss, after filling the sole, must be packed a little under the shoe, and can be wetted as required. Where the hoofs are naturally weak and brittle, they require additional or more frequent softening.

Foul of Foot in cattle resembles the diseases we ve just been describing in the horse, and in fact is arly identical with them. Sometimes there is a conspi- ous crack between the claws of the hoof, followed by in- mmation and secretion of offensive matter; and at other nes a tumor appears above the coronet, between the hair d hoof, attended with pain and inflammation: sometimes e mischief is owing to foreign bodies finding lodgment out the hoof. The remedy for this complaint is removal such foreign bodies, simple ablution, astringent washes, of alum, sugar of lead, and white vitriol, and dressings ith some stimulant, among which equal parts of soft soap d turpentine has been much commended. According to r Skerret, three or four dressings never fail to produce a re. It is alleged the constitution sometimes participates the disease, if it does not produce it, as in the case of the urrain, which within these few months visited us. In ese cases cleanliness, bleeding, a laxative, and sometimes oultices may be required. Foot-Rot is the name given this kind of disease as exhibited in sheep, among which commits such disastrous and ruinous consequences, at- cking, if neglected, the whole flock, so that in feeding ey actually crawl on their knees, before they become s victims. Hence it is regarded in the last degree con- gious. After a good deal of investigation, however, we ave arrived at a different conclusion; and we discover its history nothing more than the results of that domes- c state to which we have subjected this useful creature. y nature, not unlike the goat, it frequents the summits of e lofty mountains, where its hoofs, altogether analogous those of the horse, are exposed to much tear and wear. hen from these alpine regions we transfer the sheep into r grassy lawns, our moorish lands, or sandy soils, this earing away of the crust is put an end to; it grows long, d proves a great encumbrance. In this state it is ex- osed to many injuries, among others from the long grass the pastures, and itself necessarily injures the soft parts eneath; and hence lameness, inflammation, suppuration, to e extent of casting the hoof, are the consequences. We ave not here space fully to prosecute the subject, and must erefore take the liberty of referring to another quarter r a more ample elucidation of the subject.[1] The cir- umstance of the disease occurring epidemically arises, we onceive, from the whole flock being placed in precisely milar circumstances. The symptoms of the disease are uite analogous to those so largely dwelt upon in the orse; and we would insist upon prevention rather than ure. We advise the providing the flock with regular walks milar to their natural ones; or that they should be made walk on the hard road, or to be put regularly into a fold with a hard and gravelly bottom. Long rough grasses should be cut down in their pastures. Regarding the treatment, suffice it to say, that the principal points to be attended to, are paring away the detached hoof, and dressing the surface with some caustic, of which butter of antimony is the best.

Leg evil.

Leg Evil, or Black Leg, is a term much, but not very definitively, used among shepherds, for various disorders of the limb, some of which are sufficiently formidable. One of them begins at the hoof or knee, and soon makes the animal quite lame. The part is covered with small blisters filled with a dark-coloured fluid, and the skin now breaks out in sores. The complaint is said to be highly contagious, and separation accordingly is enjoined between the sound and unsound. The wool is to be removed from the diseased part, the sores, after being well washed, are to be dusted with burnt alum, and the whole limb to be wrapped in a cloth spread with Turner's or a more stimulating cerate. Another disease, which also goes under this name, is a chronic rheumatic affection, now in one limb and now in another. The joints become stiff and somewhat swelled, and the lameness is obstinate; but the disease, although tedious, is not fatal. A third disease corresponds to quarter-ill in cattle.

Diseases of the digestive system. Teeth.

Leaving the all-important instruments of movement, we proceed to the internal parts, and commence with the Digestive System. We begin with the Teeth. The history of the dental apparatus furnishes the most specific evidence regarding the age of the individual, especially in early life; and hence the importance of minute acquaintance with the following particulars respecting the horse. The foal at birth has no teeth; but in a few days, two above and two below: the central, make their appearance, and soon after four others, on the sides of these; in three or four months more, other four, the *corner* teeth, as they are called, appear. These twelve in front of the mouth continue without alteration until the colt is about two and a half years old, when he begins to shed his teeth. The two central teeth above and below are the first that fall out, and the new teeth, called also horses' teeth, are much larger and stronger than the former. Between the third and fourth year, the next incisors above and below, fall out, and are replaced in like manner; and between the fourth and fifth year the corner teeth are changed. When the animal is about a year old, four molars appear in each side of each jaw, and when about eighteen months, a fifth. At the age of two and a half, the first temporary molar drops out, and a permanent one takes its place; at three and a half the second, and at four and a half the third. About this time the sixth and last molar appears, and is a permanent tooth. During the fourth year the tusks or tushes appear. The change which takes place between the fifth and sixth year, is the gradual wearing down of the outer edge to a level with the inner. At seven the outer incisors have become a little longer, and the black mark smaller; at eight the mark is generally lost. After this period, a judgment is to be formed by the cavities in the upper teeth. About ten, the central teeth have lost their marks, the two next have but little left, though they are still readily seen in the upper corner ones; by the twelfth year they too have also disappeared. The tushes, like the incisors, gradually change their form. At first they are small, sharp, and shell-like, with a concavity on their inner surface; the teeth become gradually larger, and the concavities less, and at about the age of eight they are nearly lost. About twelve, the inside of the tusk becomes somewhat rounded in form, and ere long is quite round, blunt at top, and of a yellow colour. This colour, with advancing years, pervades all the teeth. The age of the ox and sheep, in their earlier years, is ascertained by a similar acquaintance with the changes of their dental apparatus; in later years from their horns, a year being allowed for every ring, answering to the shedding of their coat; and three additional in the ox, for the space between the oldest ring and the tip.

---

[1] Quarterly Journal of Agriculture, vol. ii. p. 852.

Diseases of the teeth.

The Diseases of the Teeth attracting attention are but few. The edges of the grinders, at all ages, are apt to get rough, wounding the inside of the cheek, and so interfering with mastication. These asperities must be filed down with the rasp. Not unfrequently the growth, especially of the grinders, is irregular; a process of one of them often projects, injures the opposite jaw, and interferes with the proper discharge of their functions. The cure is to reduce this tooth to the level of the others by means of the rasp, forceps, or chisel, or, if loose, to remove it.

The mouth.

Proceeding to the Mouth, we remark, that its lining membrane, including the tongue, is apt to be affected with

Aphthous thrush.

Aphthous Thrush, a crop of small vesicles or pustules, which may go on to ulceration. This would appear to be a disease of the mucous follicles, and requires the greater attention, as it is sometimes associated with strangles. These symptoms are seen in the horse, and also frequently in cattle and sheep, commencing with small blisters, and the peeling off of the cuticle of the tongue and mouth, whereby much difficulty is experienced in taking food; and fever is sometimes present. In these cases, laxatives, antacids, such as chalk and diaphoretics, should be prescribed, and an astringent wash to the parts, as of borax and alum.

Lampas.

Lampas is often described as a painful swelling of the lower bars of the palate, projecting above the surface of the front teeth, and interfering with feeding, as a disease of young horses, connected with the shedding of their teeth, and occasioning fever. It is not, however, so much a disease, as a natural and salutary process, which, in general, is best let alone, and in which cruel remedies, such as firing, should never for a moment be thought of.

Tongue.

The Tongue is liable to various injuries. Frequent trouble is given in all the domestic animals, from the lodgement of sharp irritating substances about the tongue, throat, and teeth. The offending body may be a needle, thorn, or sharp bone; and in consequence, the animal declines his food, appears sick, and may froth at the mouth; so that in the dog we have known this accident mistaken for *rabies*. In cases of this sort, the parts should be carefully examined, and on the removal of the offending body, the cure is readily accomplished. Inflammation of the tongue occurs spontaneously in the lower animals, as sometimes in man; but is more frequently seen as the result of accident. Awkwardness and violence in administering balls and drenches are frequent causes; and the horse, in sleep, sometimes severely bites his tongue. From the violence used in administering physic, we have seen the inflammation run so high, as to terminate in gangrene. The disease is characterised by great swelling and prolongation of the organ, thereby impeding breathing. Free bleeding from the part, by scarification by a sharp knife, and general bleeding, are the most efficient remedies, and sometimes a part of the organ must be cut off. If only a couple of inches are removed, no alteration is produced in feeding; but if double or more be removed, the animal cannot drink till it gets its nose under water, when it can produce a vacuum, and employ suction. From the same kind of rough handling, the frænum is often torn, so occasioning ulceration and soreness; but with mild dressing, the sore soon heals. Sometimes we have seen the injury so extensive, that amputation of a part of the member became necessary. The hemorrhage from excision is seldom troublesome.

The blain.

The Blain, as originally described in cattle, consisted, we believe, in an obstruction of the ducts of the sublingual glands, whereby the saliva was confined, occasioning a tumour at the root of the tongue, which produced protrusion of that member, and threatened suffocation. This disease is likewise known in man. All that is required is to make a free opening with the lancet. By an extension of the term, the name is applied to the occurrence of vesicles, or small blisters in this locality, which pervade the frænum and the gum. They occur in the horse as well as in cattle, going on to troublesome and protracted inflammation, sometimes threatening mortification. Scarification may be used, and strong solutions of alum and borax, with tincture of myrrh, and Friars' balsam.

The Parotid is the most important of the salivary glands, largely secreting this important fluid, and pouring it, through its duct, into the mouth. With the situation of the gland, and the course and termination of the duct, every veterinarian must be familiar, that he may avoid injuring them, and be able to heal them; no easy task, when they have been divided. The principle of cure is sufficiently evident. In the case of the duct, it is to bring the divided ends as closely together as possible, and to keep them there, at the same time preventing the escape of any saliva from the wound. This may be tried by the skilful application of a fine pin, scarifying the edges, if fistulous, and keeping the integuments closely approximated. To rouse these parts to the adhesive inflammation, the cautery is sometimes used; but we have found a strong solution of corrosive sublimate, (ten grains to the ounce,) more efficacious. If we fail in this method of cure, an artificial opening or canal, as much as possible in the natural course, must be made between the divided part and the mouth; and when this is thoroughly established, we must connect with it the part of the duct coming from the gland, healing up the superficial parts. Concretions sometimes occur in the duct. We have seen them occasionally as large as marbles, rattling in the cheek like dice. If troublesome, and requiring to be removed, this must be effected from the inside of the cheek, or if from the outside, the wound must be dressed very carefully with a pin, as in bleeding. In certain cases of cold and sore throat, the gland may inflame and swell, becoming conspicuous, when it forms Mumps; as do also the other salivary glands, especially the submaxillary, constituting what the farriers call Vives. For these complaints cruel modes of treatment used to be adopted, which happily are abandoned. Reduced feeding, possibly bleeding, blistering, and time, are all that are required. Sometimes these glands become involved with others, in strangles, when they will again come under notice.

Concerning the Œsophagus, to which we next proceed, the only complaint to which we shall allude is that of Obstruction. This may arise from tumours and schirrus, to which we may subsequently advert; now we shall insist only on what is called Choking, or obstruction of the passage by a large morsel of food, witnessed more in cattle than in horses, and most frequently when they are feeding upon turnips, potatoes, carrots, and such like. The obstruction usually occurs at the bottom of the pharynx and commencement of the gullet, not far from the lower part of the larynx, which we have seen mistaken for the foreign body. The accident is much more serious in ruminating animals than in others, as it immediately induces a suspension of that necessary process, and of digestion, followed by a fermentation of the food, the evolution of gases, and all those frightful symptoms, which will be noticed under the disease *Hoven*. The difficulty in breathing, and the general uneasiness of the animal, usually direct at once to the nature of the accident, which examination brings under the cognizance of the eye and hand. No time must be lost in endeavouring to afford relief; and the first thing to be tried is, by gentle friction, and pressure of the hands upwards or downwards, to see and rid the animal of the morsel. Failing in this, we mention first, the great virtue we have frequently found in the use of mild lubricating fluids, such as warm water and oil, well boiled gruel, &c. The gruel is grateful to the animal, which freely tries to gulp it, and often succeeds. Whether this is owing to the lubrication of the parts, or to the natural action superinduced, it is unnecessary to inquire; but the fact we know, that a few pints of warm gruel have often proved successful in removing the obstruction. If this remedy should be ineffectual, the foreign body may perhaps be within the reach of the small hand which a kind dairymaid may skilfully lend for the purpose. If this good service cannot be procured, the common probang must be used, the cup-end being employed. Other and more complicated instruments have been invented, acting upon various principles, some, for example, on that of bruising the obstructing body, and the use of these requires considerable skill. Disappointed in all, we must finally have recourse to the knife. We have cut into the œsophagus in the horse, merely twitching, without casting him, and extracted the foreign body with facility. Great care may afterwards be requisite, as the gullet does not always very readily unite, and death sometimes follows. The best treatment, we are persuaded, consists in applying a stitch or two of the interrupted suture, of fine catgut, so closing the divided parietes of the gullet, and healing the external wound at once by the first intention; the cure is promoted by the application of a carefully graduated pad and bandage. The food must be spare and soft.

In passing to the ABDOMINAL VISCERA, we shall premise a short account of *crib-biting* and *wind-sucking;* practices which are said to increase the tendency to indigestion and colic, and to lower condition, rendering those animals which practise them unsound. A CRIB-BITER derives his name from seizing the manger, or some other fixture with his teeth, arching his neck, and sucking in a quantity of air, with a peculiar noise. After a time the abdomen is evidently enlarged. The habit is most common in young horses, but is infectious, and unless the offender is secluded, spreads widely. The best remedy is a muzzle made for the purpose. It consists of an iron rack, so wide as to allow the horse to seize his food, and yet so narrow as not to permit the passage of the teeth; and this should be applied so long as the practice is persisted in. The strap round the throat is in common use. WINDSUCKING consists in swallowing air, without fixing the mouth. The horse presses his lip against some hard body, arching his neck, and gathering together his feet. It may be prevented by applying the strap, which when studded with one or more sharp points or prickles, opposite the lower part of the jaw, will effectually prevent the animal's assuming the position in which he sucks in air.

COSTIVENESS, a complaint to which, from the great changes in their feeding, all the domestic animals are peculiarly liable, is interesting not only on its own account, but also as leading to other and more dangerous disorders. Calves are very subject to it, when first put on dry meat; and it is highly necessary they should speedily be relieved, as colic and enteritis are the frequent consequences. In the horse it is very apt to occur from eating old luxuriant grass; and it is then occasioned by the felting together of the woody fibre, whose length interferes with its division, so that it accumulates in great masses. This is most apt to occur in the rectum, and to an extent not to be overcome by the most strenuous efforts of unassisted nature. The same state is also seen in dogs. Hence the manual assistance which from time immemorial has been rendered by the farrier, under the name of RAKING and BACK-RAKING, introducing the hand or finger into the rectum, and emptying its contents. In some cases this is imperiously required; but in many we conceive the practice might well give place to the use of injections with the help of the syringe. In proceeding to afford relief by physic, some preparatory care is necessary, concerning which we refer to a former page. The bowels once cleared, the tendency should be met, and counteracted, by appropriate food.—In this connection we may mention, that several cases have occurred to us where the bad health of horses seemed owing to ACIDITY IN THE STOMACH. In these, the appetite was lost and vitiated, so that old lime and dirt were preferred to wholesome food. The animal was dull, the coat staring, with a tendency to perspiration, the pulse being natural. Loss of the cud in cattle and sheep sometimes arises from the same cause. Having noticed the craving for lime, we prescribed magnesia, and found great and immediate benefit, so that the practice, we conceive, merits more extensive trial.

Veterinary Science.

Acidity.

Stomach and bowels.
Spasmodic colic.

That there are cases of pure SPASM OR CRAMP OF THE STOMACH AND INTESTINES, can admit of no reasonable doubt, although they may often be overlooked and misunderstood. In the horse, it is said to occur most frequently in the ilium. It comes on suddenly, and the pain in the part is intense. The animal shifts his posture, looks at his flank, paws violently, strikes his belly with his feet, lies down and rolls about. In a few minutes the pain ceases, and the horse shakes himself, and begins to feed; but, on a sudden, the spasm returns, with the painful symptoms; ere long there may be another remission, to be followed by another paroxysm, till it terminate in permanent relief or violent inflammation of the parts. Among the most common causes of this complaint, are the drinking of cold water when the animal is heated, sudden exposure, under such circumstances, to cold and damp, mechanical obstruction, especially from foreign bodies, and over-feeding upon green meat. The distinguishing symptoms between colic and inflammation, into which it is so prone to run, are, that in the former there is no previous cold fit, the pulse is comparatively little affected, there are intervals of relief, and pressure on the abdomen does not aggravate the suffering, but relieve it. The treatment must be prompt, and it consists in the immediate administration of anti-spasmodics, of which laudanum and turpentine are among the most powerful. An ounce or two of laudanum, and three ounces of turpentine, in a pint of linseed oil, often afford instant relief. If we are disappointed in this result, venesection should be immediately practised, as bleeding is the most powerful of all antispasmodics; fomentations, or smart counter-irritation should be applied to the abdomen; large warm injections prescribed, and laxative medicine; soft meat alone should be permitted; the horse should be kept comfortably warm, and have gentle exercise for a day or two.

Indigestion.

The food, after being subjected to the process of mastication, passes into the stomach, where it should undergo the still more important one of *Digestion.* This is chiefly effected by the agency of a peculiar secretion of the organ called the gastric juice, which possesses a solvent power superior to that of any other in nature with which we are acquainted. Even if meat be tainted, it corrects that taint, and when the ingesta have a strong tendency to acidity or fermentation, it arrests or suspends that tendency. This occurs in man, and in the lower animals; though many accidents are apt to interfere with its healthy exercise, these varying with their varying structure and habits. The stomach of the horse is small, and incapable of containing much at a time, so that it soon passes off. The stomach of the ox and other ruminants is complicated, the food passing from pouch to pouch, until the process of digestion is completed. Whatever interferes with the healthy discharge of this function, will naturally lead to INDIGESTION, which, in the lower animals, unlike to what occurs in man, leads directly to disease of the most rapid and fatal character. Of the predisposing causes—to turn first to the horse—one of the most influential is any thing which interferes with mastication. Hence the prejudicial effect of eating too fast, whereby there is a deficiency of the comminuting process, and a paucity of saliva, and hence the evil of the dental apparatus being impeded in its play. Another, and if taken singly, perhaps the most important cause, is a surfeit, overloading the stomach with more than it can manage, especially after a long and fatiguing fast, exhausting the vital powers. White mentions three cases he had known where a horse had got to the corn chest during the night, and was dead before morning. Other causes, however, are to be added, one of which is over-drinking. If the horse drinks largely at the time when he feeds, it washes the food from the stomach ere it has undergone the salutary changes above alluded to, and thus is prone to fermentation. Sudden change of food is another cause, as from soft to dry; and some articles more than others, turnips, carrots, potatoes and grass, more than hay or oats, and peas more than barley. Another cause is being put to hard work on a full stomach. When from such causes as these the stomach is oppressed, indigestion arises, and under one of two forms; the food either undergoing no change, forming a dangerous load, or running rapidly to frightful fermentation. The former is less alarming, and treatment will do much: purgative drenches and injections are to be administered. It is in this state of matters that *acute foot founder* is apt to arise, as noted above, where its appropriate treatment is mentioned. In the latter alternative, where fermentation occurs, one of the most fatal and fearful diseases of our domestic animals is produced. The horse may be seized on the road, and if pushed to a fast pace, it is often certain death. He slackens his pace, wishes to stop, and attempts to lie down. Sometimes he falls down as if shot, the moment he is stopt; at slow work he sometimes quickens his pace, and is unwilling to stand. In the stable he paws the ground with his fore-feet, lies down, rolls, sometimes quite over, or lies on his back. When the distension is not great, he may lie tolerably quiet for several minutes, but when considerable, he neither stands nor lies a minute, and is no sooner down than he rises again; he generally starts all at once, and again throws himself down with great violence. He strikes the belly with his hind-feet, and often looks anxiously to his flanks, sits up as a dog, and sometimes attempts to vomit. As the disease proceeds, the pain becomes more and more intense, the horse darting himself about with terrible violence; every fall threatens to be his last; perspiration runs off in streams, and his agony appears extreme. The belly is always swollen, and the girth may be torn. On dissection, the stomach is frequently burst, the belly full of its contents, and of gas, and the diaphragm ruptured. When death is delayed, the bowels are found inflamed, often twisted, and sometimes burst. The treatment consists in arresting the fermentation, and re-establishing the process of healthy digestion, which is to be effected by the most powerful stimulants and carminatives. Several formulae we supply below.[1] These must be administered as a drench; the abdomen should be rubbed; the animal should be walked slowly about, and supplied with a good bed, and room to roll about. If there be no relief in half an hour, a second dose may be given, and ere long, if still required, a third. The probang too may sometimes be introduced, and the relief it affords, is sometimes considerable. In the majority of cases, this treatment will succeed, if the bowels have not been previously inflamed or burst. This form of the disease is nearly confined to heavy draught horses, which are long in the yoke, have keen appetites, and devour greedily, and with them it is very common. The complaint has received various names in different places, such as *Gripes*, *Colic*, *Flatulent Colic*, *Spasmodic Colic*, *Frett*, *Batts*, *Enteritis*, or *Inflamed Bowels*, and *Acute Indigestion*, &c. This superabundant, not to say confused nomenclature, is annoying not only to the ignorant, but even to the well-informed, and should be rectified. The disease corresponds to *Tympanitis* in man, and the old name HOVEN is perhaps the best.

HOVEN. BLOWN. FOG-SICKNESS. The name Hoven universally expresses the occurrence of the above disease in cattle and sheep, the structure of whose digestive organs renders them peculiarly liable to the complaint; while the sudden changes to which they are exposed in feeding, prove exciting causes. Thus it is often witnessed in animals removed from confinement and winter feeding, to the luxuriance of the clover field; and in house-fed cattle, from the exhibition of rich food, such as pease meal and beans, often supplied to enrich their milk. We have already mentioned that it sometimes proceeds from obstructed gullet. The symptoms bear so close a resemblance, both in their progress, and termination in rupture and death, to those so fully described above, that we shall not repeat them. The treatment mostly corresponds, and it must be equally prompt. The mixture of the oils of linseed and turpentine is nearly a specific. In addition, the probang is often used with advantage; but so violent and rapid are the symptoms, that recourse must sometimes be instantly had to the operation of PAUNCHING, which, though apparently a desperate remedy, is generally attended with success. The place for puncturing the paunch is on the left side, in the central point between the lateral processes of the lumbar vertebræ, the spine of the ilium, and the last rib. Here the trochar may be introduced without fear. If air escape rapidly, all is well. The canula may remain in for a day or two, and on withdrawal, little or no inconvenience will usually manifest itself. If no gas escapes, we must enlarge the opening freely, till the hand can be introduced into the paunch, and its contents removed, as we have sometimes seen in prodigious quantities. This done, we should close the wound in the divided paunch with two or three stitches of fine catgut, and carefully approximate and retain the sides of the external wound, and with rest, wait for a cure, which is often as complete as it is speedy.

The BRAXY, so fatal in sheep, comes to be considered here. It has been divided into several varieties, as *bowel sickness*, *dry braxy*, &c. The disease particularly attacks sheep when in good condition; and when they are suddenly deprived of their wholesome food, and forced to feed upon coarse grass and heather, &c. Constipation appears the exciting cause; violent inflammation succeeds, with much agony to the sufferer; great tendency to swelling, so that the viscera and the abdominal cavity sometimes burst; and withal, a tendency to mortification and sinking, so that after speedy death, the touch of the viscera, and even the carcase, is intolerable. The disease is often stated to be hopeless; but if met early, and treated on the principles already laid down, this gloomy view should not be taken.

Associated somewhat with the last disease as to cause, yet differing materially as to symptoms, is the STOMACH STAGGERS, whose immediate cause is usually stated to be in the stomach, while some of its most conspicuous symptoms affect the brain, which we are persuaded is decidedly implicated; hence its compound name. Mr White conlers that the complaint is caused by enormous distension of the stomach; in a marked case, sixty pounds of rd and imperfectly-masticated food having been found in e viscus, the coats being stretched and attenuated; and approximation to this state being seen in many others. e horses most liable to the disorder are such as have en exhausted by hard work, unwholesome food, and old e. The disease often makes its appearance first after a g fast, and over-work, but frequently also when the horse at grass. Hence it has been supposed that the quality the food acts as a cause, especially rank grasses, and noxus weeds, such as the common rag-weed. It has often been garded as infectious, but perhaps is only endemic. It apars most commonly among agricultural and cart horses, ich sometimes have fallen victims in scores. In a few es, it seems to proceed to regular *Hoven*. The most minent symptoms are the horse's hanging his head, or ting it in the manger; appearing drowsy, and refusing d; the mouth and eyes being tinged of a yellowish cor; there is twitching of the muscles of the chest, and fore-legs appear suddenly to give way, though the anil seldom falls; the pulse at first is not affected, but in r or five days inflammation of the bowels or lungs suvenes; the belly is costive, and the dung hard and ny. Lockjaw frequently occurs before death. The best atment is to endeavour first to empty the stomach of its d, and then to excite the process of digestion. For the mer of these intentions, the stomach-pump should be ployed, though it is not so applicable in animals as in n; or tepid water should be administered in large quanes, which, passing speedily from the stomach, is supposed remove much of the load. Searching and stimulating atives are also indicated; most of all croton; also such loes and calomel, with ginger or carbonate of ammonia. these means should be added enemata, and, by and bye, ne slight cordial. If the head symptoms are prominent, temporal artery or jugular vein may be opened, and od drawn with advantage. Finally, there must be steady ercise, and frequent and careful feeding, under which atment many cures are effected. The FARDLEBOUND cattle and sheep is, we believe, nothing more than a mocation of this disease. In this variety it has been ascerned that the *maniplies* are most involved, its secretions suspended, and its contents become dry, hard, and caked, solid mass. Though the constipation is great, yet re is sometimes the appearance of a slight purging, which y deceive the practitioner.

---

[1] Linseed oil raw, one pound; oil of turpentine, from two to three ounces; laudanum from one ounce to two ounces;—the whole administered as a doze. Or hartshorn, from half-an-ounce to an ounce; or chlorate of lime, half-an-ounce given in two pints of tepid water. The following tincture may sometimes be kept in readiness:—Take good spirits, whisky or brandy, two pounds; ginger, three ounces; cloves, three ounces; digest for eight days, and add sweet spirits of nitre, four ounces. Half a pint of this tincture is a dose in a quart of warm water. In cases of pressing urgency, from one ounce to two ounces of tar may be added to half a pint of spirits, and given diluted, with great prospect of advantage, especially to cattle.

NFLAMMATION OF THE STOMACH is not a common nplaint in any domestic animal, and is induced chiefly m over-doses of purgatives, and mineral poisons, espelly arsenic and corrosive sublimate. In these cases the se is rapid, sharp, and small, the extremities cold, the piration quick; there is also the appearance of dulness l dejection, with great debility. After the bowels are ely evacuated, oily and mucilaginous liquids should be scribed, with a little opium; and the food should be y soft and spare. Arsenic was formerly given very freeo horses; and corrosive sublimate is still administered a variety of complaints. In the case of an over-dose of latter poison, white of eggs is an effectual antidote, if en in time. Without this albumen, inflammation is soon uced. For arsenic no antidote has yet been discovered. the horse it cannot be vomited, which aggravates all the nptoms. The pain of the abdomen is made very manifest the wistful looks of the sufferer directed to his flanks; and by the profuse perspiration, thready pulse, great weakness, violent straining and purging, terminating in convulsions and death. The stomach-pump should be used as speedily as possible: after this we must boldly use the antiphlogistic regimen, latterly somewhat supporting the strength, by bland food and anodynes.

Peritonitis.

The Peritoneum, as is well known, is a membrane which lines the walls of the abdomen, and invests all its viscera, forming the external covering of the stomach, intestines, liver, &c. Hence it bears a principal share in the acute inflammation of all these organs, which inflammation is very ready to spread from one to another, till all the inflections of the continuous membrane are involved. ACUTE PERITONITIS, then, is a very dangerous affection, attended with marked symptoms of severe general pain in the abdomen, with high fever, quick pulse, great costiveness, scanty urine, &c. Of all domestic animals, the disease occurs most frequently in the dog. It is produced by sudden chills and damp, after being over-heated, by wounds, sometimes after castration, by the introduction of air into the abdominal cavity, or by irritating substances, as happens in the escape of the contents of any of the viscera, in which case it is almost necessarily fatal. The treatment required is the antiphlogistic, in its greatest rigour, and especially at the commencement, with large bleeding, strong purging, as with croton oil, the free action of the mucous very much relieving the peritoneal membrane; also large enemata, and strong counter-irritation rubbing the abdomen with some powerful epispastic.

Ascites.

Besides appearing as an acute disease, peritonitis often shews itself in a chronic form, and in both of these aspects it is a common cause of ASCITES, DROPSY, or an effusion of serous fluid into the abdominal cavity. When this follows a violent inflammation, it is usually accompanied with an effusion of coagulable lymph, which more or less agglutinates the parts together, and it is highly dangerous under this form. When the inflammation is moderate, the dropsical affection is not so dangerous. Its symptoms are marked; there is tension of the abdomen, with a feeling of undulation when struck, great thirst, short breathing, and scanty urine. Together with the internal effusion, there is sometimes present anasarca of the abdominal parietes, sheath, and other parts. Here laxatives and diuretics[1] are the most appropriate remedies. In many other cases, dropsy is purely a symptomatic affection, arising not from any complaint of the peritoneum itself, but from watery effusion, the consequence of impeded circulation towards the heart. Enlargements of the liver and spleen, anomalous tumors in the abdomen, and various diseases of the heart and lungs, operate in this way. The complaint is not very common in the horse, but we have frequently witnessed it in mules and donkeys. Nor is it uncommon in cows and sheep, being often in them conjoined with a similar affection in the chest. The dog, when labouring, as he often does, under the complaint, loses his appetite, the countenance is haggard, the appearance dejected, abdomen distended, and perhaps he is finally suffocated. In these cases, temporary relief may be afforded by TAPPING with the trochar; when, from cattle, five or six gallons may be drawn off, and sometimes with permanent relief. In conducting the operation, care must be taken that the abdomen be swathed, and kept compressed. When dwelling upon the peritoneum, we must not omit to mention that both it and its folds, as in the OMENTUM and MESENTERY, are peculiarly liable to a variety of anomalous tumors, and

Tapping.

---

[1] Nitre, dose from half an ounce to an ounce; foxglove or digitalis, dose one to two drachms of the powder; cream of tartar, dose one wo ounces; sweet spirit of nitre, *Spiritus Etheris Nitrosi*, dose one or two ounces; oil of juniper, dose one to two drachms, are ful, cooling diuretics, given once or twice a-day: Oil of turpentine, and the powdered resin, are somewhat stimulant, and therefore not ployed where there is fever; they are however more commonly and extensively used than any of the others, and are more certain in ir effects, dose two or three ounces of the oil, and from half an ounce to an ounce of the powdered resin, formed, with half a drachm inger and linseed meal, into a ball, by means of palm or other oil, or of soap.

to tubercles of various kinds, often produced by inflammation, and the occasion of obscure disease and of death. Of these diseases, **MELANOSIS** is one of the most extraordinary. It consists of an extraneous deposition of a black amorphous mass, or masses, which most frequently appear about the rectum, but may occur in other localities: it is witnessed almost exclusively in grey horses, and particularly when they are passing from a dark to a light colour. All these cases are generally obscure during life, and are more frequently suspected than demonstrated. They are often, however, seen on dissection, and a knowledge of their occurrence is essential to satisfactory practice.

Scirrhus.

SCIRRHUS OF THE STOMACH is one of those diseases which we have occasionally witnessed in the horse, though we do not remember it has anywhere been described. It occurs at the cardiac orifice, and lower part of the *œsophagus*, but is still more frequent at the pyloric extremity. Here the thickening is sometimes immense, appearing like canker of the foot, with numerous and large granulations, several inches long, and making the part feel as if distended with food. These morbid growths produce symptoms of eructation, and of acidity and distention, as already described. Anodynes may be administered; but the disease is beyond the reach of art.

Diarrhœa.

DIARRHŒA, *Flux*, *Scouring*, occurs in most of the domestic animals. It supervenes as a consequence of *superpurgation*, by which the animal is much weakened, and, in the case of the horse, to his serious detriment. Physicing used to be practised far too freely and frequently; and the regulating of this fashion is one of the most decided improvements in modern practice. Diarrhœa, however, often occurs spontaneously, the result of change of food, irritation in the bowels, or chill after over-exertion. When moderate, the pain is inconsiderable; but when aggravated, the mucous membrane, which is the seat of the disease, acquires a tendency to inflammation, and griping and colicy pains are the consequence. It is most frequently witnessed in what are called *washy* animals, whose loins are narrow, with a long space between the ribs and ileum; and this remark holds good of cattle, sheep, and dogs, as well as horses. The disease should always be speedily checked. If the food be at fault, it should be regulated, and green meat should be withheld: if there be ground to suspect any existing irritation, it should be removed by a laxative; and chalk, or chalk with a little powdered opium, may afterwards be administered; this is a powerful remedy, as is also catechu. Starch gruel should be given, and cold guarded against. Some horses, in going to hunt, apparently from the excitement, are troubled with occasional diarrhœa. Starch gruel, with chalk and a small quantity of powdered opium (a drachm for a dose), will generally prevent it.

Molten-grease.

MOLTEN-GREASE, the *Gras-fondu*, is often associated with more aggravated cases of diarrhœa. It derives its name from the appearance of fatty matter, forming a crust, or partial covering to the fæcal pellet. It is usually supposed to have a constitutional origin, and to be connected with some inflammatory tendency, more especially of the mucous membrane of the lungs, or with general fever. Be this as it may, it is often produced by violent exertion in a horse, which is not prepared for it, being fat and unaccustomed to exercise. The symptoms of threatening fever are present, and venesection is often the first step in the cure; the remaining treatment is the same with that of diarrhœa.—

Dysentery.

DYSENTERY, *Cling and Breckshuach*, in sheep, is likewise an affection of the mucous membrane of the intestines. It differs from the foregoing, in having a tendency to be local, especially in the large intestine, and termination of the gut; and also in being more violent, more apt to produce febrile action, and effusion of bloody mucus and lymph-like matter, sometimes resembling membranes, and to run on to deep and troublesome ulceration. The blood is sometimes coagulated on the dung, and in such quantity as, with other secretions, to receive the name of **THE BLOOD**. Upon the whole, it is a more dangerous complaint than diarrhœa, and the symptoms, though to a certain extent corresponding, are more severe. Great promptitude, therefore, should be used in endeavouring to effect a cure. In cattle, it is generally easy, by administering a dose or two of salts; a single dose often at once checking the disorder. In sheep, chalk and warm milk, followed up with catechu and opium, are very efficacious. In all the affected animals, the diet must be carefully regulated, and small doses of calomel, chalk, and opium given.[1] This usually acts as a charm, altering the morbid secretions, and affording relief. Anodyne clysters may also be used, and cold must be avoided.

OBSTRUCTION OF THE BOWELS may arise from a variety of causes, with which the veterinarian should be familiar, and the disease may be more acute or chronic in its nature. To the former category belong violent local spasm and inflammation, producing intussusceptio and death in a few hours. In enteritis and peritonitis likewise, there is sometimes a remarkable and very complicated twisting, which seems by its mechanical action alone to obstruct all descent of the ingesta. Herniæ, external and internal, are additional causes. To the latter class belong various tumors, which are prone to occur, and schirrous contractions of the canal itself, and the presence of foreign bodies. In all these cases the practitioner must be on the alert. On the treatment of inflammatory attacks we have already dwelt. **INTUSSUSCEPTIO** is a protrusion of an upper into a lower part of the bowel, or from inverted action, the reverse, as may be seen in the finger of a glove. It is a frequent cause of obstruction, as connected with inflammation, and is often witnessed after death: it is very common in dogs, and more frequent in sheep and cattle than in the horse. The extent to which it may occur is considerable, reaching to many feet of inverted intestine. Sometimes it is near the anus, and a part may protrude, and slough, and yet the animal recover. In a variety of this complaint, occurring in the rectum, the result of constipation, the part, impacted with hardened fæces, which it cannot evacuate, is forced onwards by the peristaltic action, and is protruded a hand-breadth, or even to double or triple that extent. In these cases, the gut must instantly be relieved, and then its return is easily accomplished. Cases of **HERNIA**, both external and internal, sometimes occur in the horse, usually produced by violent exertion. The latter cases will usually be fatal; the former occur in the scrotum of the perfect horse. If immediately detected and reduced, the animal may be saved. **FOREIGN BODIES**, which usually produce obstruction, are called balls, and are distinguished as hair, dust, and calcareous balls. The **HAIR-BALL**, very common in cattle and sheep, is produced by animals licking their coats. The hair thus introduced into the stomach, and there supplied with some nucleus, by the constant and almost violent rotatory action of the part, is speedily converted into a ball, most regularly and thoroughly felted. It may continue a long while in the stomach, and till death. The **DUST-BALL**, most common in horses, derives its name from being composed chiefly of corn and barley dust, saved in grinding meal, and used as food. It owes its origin to the same phenomena occurring in the stomach, but more frequently finds its way into the intestinal canal. There are often several of them, as of the former. They are almost exclusively found in those animals which have been fed on the substance. Whether the **CALCAREOUS BALL** has a different origin, we do not know; but it is of most common o urrence, and is generally found in the intestine, often in t caput cœcum. Its comparative frequency in some lo- c ties is ascribed to the calcareous character of the dis- t t, or of the water drunk. It often acquires a great size, w hout pain or trouble. At other times, however, stealing o gradually, it undermines the health, and destroys life. In a advanced stage, no doubt can remain as to the nature of tl disorder. The countenance is haggard, the eye dis- tr sed, the back up, the belly distended, the respiration b omes hurried, bowels habitually costive, and sometimes tl horse will sit like a dog, upon its haunches. Relief may fi quently be afforded. Strong purgatives and large injec- ti s must be given, and under their continued action the o nding body is sometimes removed.

---

[1] Calomel, from one drachm to two drachms; chalk, from half an ounce to one ounce; opium, half a drachm to one drachm.

Various worms, some truly, others erroneously reputed s h, infect the alimentary canal in the domestic animals, a frequently occasion more alarm than is at all necessary. C the former kind are the round worm, *teres;* the thread w m, *ascaris;* and the tape worm, *tænia.* Of the latter a various species of the extraordinary *bot*, the larvæ of the *b ze*, or *gad-fly.* In the horse, the tænia is very rare; in tl dog, exceedingly common. When the horse is un- d -fed, his bowels are full of the teres and ascaris; and the a earance of his staring coat, want of flesh, and voracious a etite, betoken it. The teres is somewhat larger than in m , the ascaris darker. They occasion gripes and diarrhœa, b the mischief they produce is not great. The principal h itat of the ascaris is the cœcum, although they are some- ti es found in countless multitudes in the colon and rec- tr . Turpentine is a deadly poison for all these worms; b this medicine, so harmless in man, acts most disagree- a y in the lower animals. Hence it must not be given to tl m pure or in large quantities, especially to the dog, but m ed, in small proportion with other oils, as linseed, or in a ill, or enclosed in a piece of gut, and with these pre- c tions, it may be found at once safe and efficacious. In d s, the teres is the most common, especially in puppies; t tæniæ the most prejudicial. The ascaris likewise tor- m nts them. If left undisturbed, the two former often occa- s n *fits*, followed by emaciation and death. Iron filings, two d chms to a dose. are highly reputed as an anthelmintic for d s; but we believe turpentine, or small doses of tartar e etic, to be more efficacious.

The Œstridæ, comprehending the Gad or breeze flies, a not numerous in Britain. though the genus *Gasterophi- l* containing several British species, has been distinguish- e from the *Œstrus* by Dr Leach. It is the larvæ of the fo ner which invade the horse, while those of the latter at- t k the ox and the sheep. Two species molest the horse, m king the stomach and intestines their habitation; whilst i cattle, and the sheep, species of the other genus attack s erally, the skin, and the cavity of the nose. Mr Blaine in- f ns us that the dog is infested with one of these parasites, w ch he is disposed to consider a bot, but its history has n hitherto been investigated, and we suspect that it is m rely a species of tænia, which we have often noticed. e great-spotted horse-fly, *G. Equi*, which is by far the m st common, also makes the ass its occasional victim. H ving selected the individual to which her future progeny i o be intrusted, she hovers about till she is prepared to d posit her egg. She then makes a sudden descent on her v tim, and glues it to his coat, repeating the operation till f r or five hundred are sometimes fixed on a single horse, t inside of the knee and shoulders being the selected lo- q ties; for the horse, in relieving irritation with his tongue, l , and teeth, is made the unconscious instrument of con- v ing them into his stomach, where alone they can come t maturity. No sooner is this transfer made, than the larvæ a disclosed, and immediately fix themselves upon the inner c t of the viscus, where they hang in dense clusters, at- t hed by their head, which is provided with sharp hooks, and their only food seems to be the juices of the membrane, without their irritating, in common circumstances, the parts. The bots, thus taking up their quarters about the end of summer, pass the whole winter and spring without undergoing any change, except that of gradually enlarging. When arrived at maturity, they cease to retain their hold on the stomach, and before this, all efforts to force them are vain, commingle with its contents, pass into the intestinal canal, and to the horror of stablemen, are ejected in multitudes from the anus. As soon as they find a convenient retreat, they change into a chrysalis, and in a few weeks more, into a fly, which takes wing, finds its mate, and thus is prepared for repeating the extraordinary process.

Red-tailed.

The *Red-tailed horse-bot, G. hæmorrhoidalis,* is scarcely half the size of the former. This fly deposits its eggs on the lips of the horse, to the exceeding annoyance of the poor animal, which is no sooner aware of the presence of his enemy, than he tosses his head, and gallops off to a different part of the field. The larvæ taken into the stomach fix themselves exactly like the G. Equi, and differ in their future history only in this, that after leaving the stomach, and passing into the intestines, they are in no haste to make their final exit, but continue for a considerable time at the extremity of the rectum, there creating great uneasiness. Back-raking, under the circumstance, affords relief.

Ox-bot.

The Ox-Bot, *Œstrus bovis,* is about the size of the *G. Equi.* Though appropriated to the ox, this species sometimes attacks the horse. It is a cuticular insect, the eggs being deposited externally in the skin of cattle, and the larvæ inhabiting a tumor, or abscess formed round them. These tumors are usually found in the back or loins, and are often larger than a pigeon's egg. When the fly is depositing its ova, the cattle are in the extremest agitation and dismay, and sometimes become quite furious, running off, bellowing, at their full speed. The larva in its cyst gradually enlarges, while the pus that is secreted by the irritation serves for its nourishment. The tumors which are produced are called *warbles, wormals,* or *womils.* The skin and hide are permanently injured by being subjected to this process.

Sheep-bot

The Sheep-bot, *Œ. ovis,* is thought to deposit its eggs on the nostrils of the sheep, though, from the agitation of the animal at the time, it is not easy to ascertain the fact. The larvæ soon find their way to the frontal, maxillary, and other sinuses of the face; here they adhere for a time, producing considerable inflammation. When mature, the larva wriggles from its warm abode, falls into the soil, there becomes a chrysalis, and continues dormant for about two months. We refer for more ample details to the writings of Mr Bracy Clark, who has acquired such merited celebrity for his elucidation of this and other abstruse departments of the science.

Liver.

A variety of diseases are usually enumerated as occurring in the Liver, more especially in the well-fed dray horses of London, and in stall-fed cattle.

Inflammation.

Acute Inflammation is one, in which the pain of the affected part is very obscure, and the natural language of the sufferer not very expressive; nor is the symptomatic fever marked. Here a striking analogy is noted, however, between the lower animals and man, inasmuch as there generally is a sympathetic pain in the right shoulder, so strongly marked as often to be mistaken for the principal disorder, and treated accordingly. Yellowness of the eye, and mucous membranes, and of the urine, are also present. Bleeding, and purging with aloes and calomel, are the appropriate remedies.

Chronic.

Besides acute, there is also Chronic Inflammation of this viscus, marked by enlargement and softening, and not unfrequently ulceration. The characteristic symptoms are, a languid eye, unwillingness to move, indifference as to feeding, yellowness about the mouth, unthrifty coat, high-coloured brownish-yellow urine, constipated bowels, with fæces not of the natural appearance, but either of a light

Jaundice.

colour, from want of bile, or of a dark hue, from excess of it. Along with this, there is pain, often with lameness of the right shoulder. Under a course of laxatives with aloes and calomel, we frequently find these symptoms disappear, and health restored. If inveterate, it sometimes happens, as subsequently proved by dissection, that the viscus is quite disorganized, and frequently ruptured, when of course there is great sinking, and sudden death. JAUNDICE, commonly called the *Yellows*, is another disease which occurs, and more frequently in the dog and sheep than in any other of the domestic animals. Enough has already been said to elucidate its symptoms and treatment.

The rot.

The true pathology of the ROT in sheep was long ago pointed out by the late professor of agriculture at Edinburgh, to be "a direful ruin of the general health and constitution, which supervenes from deficient or depraved aliment." In Scotland it is agreed that it never occurs where there is an adequate supply of good pasture, and rank grasses are held universally to occasion it. Dr Coventry moreover stated, that if not rendered desperate by fatal complications, every flock and every sufferer may be recovered by simple means, seasonably used. When all the powers of the constitution are once prostrated, other and hopeless diseases undoubtedly appear, of which character are pulmonary consumption, and the disorganized liver, which have attracted so much attention. With this disorganization are conjoined hosts of what are called *fluke-worms*, from their resemblance to flounders and other flat fish, and whose history is yet involved in obscurity. Whether with the rank grasses of marshy lands, which the sheep under the circumstances are compelled to eat, the ova of the future parasite gets admission into the frame, is a point which remains to be investigated. The cause, however, being recognised, the disease may generally be avoided, and when it exhibits itself, the remedy is alike plain and simple,—to remove from the noxious feeding, to relieve the bowels, and supply plenty of wholesome nourishment.

Spleen.

The diseases which have been principally signalized in the SPLEEN, are *enlargement*, usually chronic, often united with *tubercles*, sometimes with *softening* and *rupture*, and of course speedy death. These diseases are not very common, and are certainly obscure, being apt to be confounded with the anomalous tumors already noticed. They may be marked by rigors, loss of flesh and appetite, but the symptoms are rarely conspicuous. After sudden death from rupture, occurring in a poney at work the day before, we found this organ to weigh not less than seventy-two pounds.

Staking.

Before leaving the abdomen, we must mention, that in taking leaps, horses are sometimes wounded in the belly, or STAKED. The wound may, or may not penetrate the cavity, which is easily ascertained by the finger. In the latter alternative, it is comparatively of little consequence, and the treatment is the same as in other skin wounds. In the former, it is much more serious. A portion of the bowel is almost sure to protrude, and the quantity is augmented by every step that is taken. Examination should instantly be made to ascertain if the bowel itself is wounded. If so, the lips of the wound must be nicely united with catgut ligatures, before the intestine is returned. If this cannot be done at the moment, a bandage and pad will prevent its farther escape, till proper assistance is procured. If the bowels are uninjured, by a little gentle manipulation they may be replaced, the edges of the external wound drawn together, and secured by pins and tow, and a bandage bound round the body, sustaining a compress over the aperture. Our dread, after this, is that enteritis may be produced. Hence the antiphlogistic regimen must be pursued, and in all its vigour. Venesection must be freely, and if there be tenderness, repeatedly used; the diet must be very spare, and of the softest kind, and with great care, a cure may be effected. Another variety of the accident remains to be noted: it is where the muscles, or other parts of the parietes of the abdomen, are torn, while the skin remains entire; a sac being formed, into which some of the abdominal contents may protrude. In this case bandages and pressure must be carefully applied, and laxatives and spare diet prescribed.

In commencing our review of the diseases of the URINARY and GENERATIVE ORGANS, we remark that in the horse considerable advantage is derived from the size of the parts, which allows the ready introduction of the anointed hand into the rectum, so that the viscera, including even the kidneys and ureters, may be carefully examined. NEPHRITIS is not a very common disease. It may be acute or chronic; sometimes it is idiopathic, sometimes caused by the exhibition of particular drugs and food. When acute, the pain is violent, there is symptomatic fever, and a peculiar straining of the body; the animal frequently lies down, and points with his nose, in his attempts to reach the seat of the disease; the urine is high coloured and scanty, and there are frequent ineffectual efforts to pass some. The treatment consists in the vigorous employment of the antiphlogistic regimen, in the free use of decoctions of linseed, in fermentations and mustard poultices, blisters and turpentine being carefully avoided. In the cow, pus is often passed with the urine, which ought, and may easily be distinguished from *Leucorrhœa*. HÆMATURIA, bloody urine, generally arises from a diseased state of the kidneys, though it is sometimes produced by diseased states and fungus of other parts of the passage, and sometimes by violent strains and internal ruptures. Genuine DIABETES, which is a protracted increase of the quantity of urine, with a change in its chemical composition, is not a very rare complaint in horses. Great thirst is usually a prominent symptom, and feverishness. The pathology of the disease is obscure, but seems to be connected with derangement of the digestive organs. Purging, especially with aloes or croton, or with salts, together with astringent medicines, such as carbonate of soda, chalk and lime, also catechu, should be used, and a change in the food, which should be of the best quality. Carrots are regarded serviceable, as also the mixture of a little pipe-clay or pease-meal with the water drunk. We have found iodine a never-failing remedy, very useful in correcting the thirst, and checking the flow of urine. CALCULI are often found in the kidneys of all the domestic animals, including the pig; but they do not readily pass down into the bladder, on account of the horizontal position of the ureter. They occasionally produce immense enlargement of the ureters, and considerable irregularity in the functions of the part.

INFLAMMATION sometimes occurs in the bladder, more especially about the neck: the symptoms are pain in the viscus, and constant micturition, with others as stated under nephritis, and the treatment generally resembles what has been advised for that complaint. The injection of a little warm oil into the bladder, often affords singular relief. CALCULUS is occasionally witnessed in this viscus, and the symptoms are well marked in the constant irritation and the dribbling of urine; manual examination speedily confirms suspicion. It is sometimes seen in valuable young colts and stots, and an attempt must be made to afford relief. This may be effected by cutting merely, or partly by dilatation. LITHOTOMY in the horse is not so perilous, or difficult an operation as in man, the space being much more ample. The following is the mode in which it may most easily be accomplished. A sound is to be passed up the urethra, till it is felt in the perinæum; an incision is then made into the canal, and a director introduced from this point into the bladder; with the probe-pointed bistoury the incision is to be enlarged on the left side of the raphe; the right hand is now introduced to the rectum, the two fingers of the left into the bladder; the stone may thus be pushed against these fingers, nd by them guided to the neck of the bladder, and so rced through the opening in the urethra. A stone weighg four and a half ounces has thus been successfully removl, and the wound healed quickly. Sometimes a soft pulpy ass almost fills up the viscus. Fungous Growths and cerations are apt to occur in the mucous coat of the cow's adder, and corresponding diseases in the horse, and in e glans penis. In the former case, they are not easily reedied; in the latter, the diseased part should be excised. astration is a formidable operation, especially in the fullown horse, and is best performed by making an incision rough the scrotum, allowing the testicle to protrude, tying e arteries, cutting the cord, and removing the gland. hese we know are but hints, but our limits prohibit details. s to Nicking and Docking, we believe the time is near hand when even the Cow-leech will perceive the abrdity of endeavouring to improve upon the fair forms of e most graceful works of nature, and will leave the horse's il, no less ornamental than useful.

Inflammation of the Udder, Garget, occurs in the are as well as in cattle, as a consequence of parturition; though it is only in the latter that it is produced from the rbarous practice of *hefting*, delaying milking, that the antity may appear the greater. In bad cases, when the ilk cannot be elicited in the common way, a fine hollow be (made for the purpose) may be introduced into the at; through this the milk flows, and the udder resumes healthy tone. In severe cases the inflammation runs so gh, that mortification is the consequence, and the udder ops off. When this threatens, blood should be drawn eely from the milk veins, purgatives should be administred, the weight of the part supported, and poultices apied. Suppuration will thus frequently be induced, and a ncture being made, will relieve. Inflammation of the lder, more general or partial, and sometimes confined to e teat, is frequently so severe in the ewe, that she reses all sustenance to her lambs, so that they actually die starvation. The treatment for the dam, is in principle, e same as that just mentioned. In the bitch the disease ten becomes chronic, and excision is necessary.

The Respiratory System includes the cavity of the ose, the pharynx, larynx, trachea, lungs, and chest, with heir several component structures. Each distinct part is able to assume morbid action, whilst, at the same time, everal of the tissues are continuous, and common to two r more of the above named parts, so that any disease atcking one, is apt to spread to others.

As it regards the Nose, the phenomena produced by its avities being infected with the *Bot*, have already been entioned. Fungous excrescences not unfrequently proeed from the turbinated bones and septum, and appear as *olypus*, so interrupting the respiration. In their more agravated form they secrete pus, and produce a considerble discharge, so that the animal may be supposed to bour under *glanders*. The remedy here is to remove e polypus with the forceps, subsequently washing the arts with a styptic lotion. Nasal Gleet from inflamation of the schneiderian membrane, has sometimes been escribed as an independent local complaint. Any obserations which we have to make upon it, will find a place, hile considering those disorders of which it frequently onstitutes a conspicuous part.

When treating of the gullet, we had occasion to mention one cause of Choking, connected with foreign bodies odging in the narrowest part of the tube. We have now o add, that draught horses, during a dead pull up hill, ometimes choke from the pressure of the collar on the indpipe. They may stagger a little before falling, or fall ithout warning. The wheels should, under the circumstances, be set across the road, and the collar thrown off the windpipe. The accident is most apt to occur when the animal is put to draw with a bite in his mouth, as often happens on canal banks. When the morsel goes down the gullet, it is intercepted by the collar, and the two pressing on the windpipe, compress it; and so many horses have been lost. A knowledge of the fact should lead to the necessary precaution. Inflammation of the larynx frequently takes place, the disease at the same time spreading from the delicate lining membrane to the nearest parts. In this way lymph is effused, and the play of the parts impeded. Sometimes the smaller cartilages themselves are altered, being thickened and contorted, and small tumors are apt to be produced, both within the tube and without it. The marked symptoms are local pain, difficulty in breathing and swallowing, and general fever: the treatment required is venesection, and the other parts of the antiphlogistic regimen. Tumors occurring in this locality in cattle, constitute the disease called Clyers, which, though it may not for a time interfere with fattening, yet speedily injures health.

Laryngitis.

Clyers.

Disorders of breathing.

Connected with the larynx and trachea chiefly, but sometimes also with the lungs, are various distressing affections of the breathing, which, from the character of the respiration, have procured for the animals labouring under them such names as these, *Piper*, *Trumpeter*, wheezer, whistler, blower, grunter, roarer, to the causes of which infirmities we shall now allude. The rima glottidis and larynx are supposed to be peculiarly affected, when there is that sharp and hasty sound which is expressed by the first two of these terms. The *Whistler* utters a somewhat shrill sound, when in somewhat continued exercise, and this is supposed referable to some cause producing contraction in the trachea. The sound of the *Wheezer* is somewhat like that of an asthmatic person, and is supposed to proceed from an over-copious secretion in the bronchiæ; it is heard even when the horse is at rest. *Roaring* is confined to the increased sonorousness of breathing, on any considerable exertion. A *Highblower* is an animal which puffs and blows loudly, dilating his nostrils, while the flanks are comparatively quiet; and in the *Grunter* it is supposed there is some altered structure in the lungs, which interferes with all considerable exertion. A horse labouring under this infirmity, when suddenly touched with the whip or spur, will at all times utter this grunting sound. In further illustration of these material infirmities, we shall dilate a little on Roaring and Broken-Wind. Mr White mentions, that he had once and again examined animals which were perfectly useless from Roaring, and had found every part healthy except the larynx, which was ulcerous. Many roarers, however, have subsequently been examined, in which the larynx was quite sound, while the lining membrane of the trachea was thickened. Tight reining has been ascertained to be a cause, the windpipe being found flattened, and bent from the bearing of the bridle. Obstruction of the nose, hepatization of the lungs, and even enlargement of the liver have been suspected. In several instances, we have noticed tumors in the passage, and a wasting of the muscles on one side of the larynx. Thick-wind is distinguished from Broken-wind. In the former the breathing is rapid and laborious, but the inspiration and expiration are equally so. In broken-wind again, the inspiration is performed at one effort, and the expiration requires a kind of double effort. The cause of broken-wind seems to be the rupture of some of the air-cells of the lungs, whereby air-vesicles are produced on the surface, and the expulsion of the air is rendered less direct and easy. It is usually produced by animals being urged to over-exertion when in bad condition, though a horse may become broken-winded in a straw-yard. Although the cure of this affection is not to be expected, yet it can often be very much

Roaring.

Broken-wind.

mitigated, and that mainly by attending to the diet, condensing nutriment into the smallest compass, keeping the bowels open, and giving little water before work.

Tracheotomy.

Tracheotomy is the operation by which the trachea is opened, the name *Bronchotomy* being often inaccurately applied to it. It is performed chiefly in cases of sudden obstruction, which cannot be removed on the instant, but which it is anticipated will soon be overcome. It is frequently practised on the horse. The operation is simple, the incision being made in the mesial line, separating the muscles, and then slitting through a couple of rings, the canula being left in. While the opening was left, we have known the roaring horse to be free from his complaint for many months; but from this operation no one would expect any thing like permanent relief.

Strangles.

The account usually given of Strangles is not so simple as it might be. It is a disease of the horse, and few escape it. It attacks them when young, colts not excepted. Generally, however, it exhibits itself at the age of four or five years, during the prevalence of pulmonary complaints. It may be defined a catarrhal affection, accompanied by a specific phlegmonous affection of the cellular membrane of the throat, tending to abscess, with slight fever. The whole cellular membrane, between the branches of the lower jaw, becomes distended with serous and lymphy effusion, acquiring a firm and solid feel, and is tender and hot; it advances to suppuration, and terminates in abscess generally of the throat, but sometimes also in other parts of the body. This alone is Strangles, all other symptoms being only concomitant or accidental. Such are the soreness of the throat, the redness and discharge from the nose, the cough, and tumefaction of the salivary glands. Inflammation of the trachea and lungs, and some say glanders, may supervene upon this complaint. The only treatment required in an ordinary case, is the application of a blister, to urge nature to terminate the process. The abscess should be opened as soon as ripe, and suppuration promoted by slight digestives. Hundreds of cases have been witnessed without one fatal termination.

Catarrh.

Common Cold is familiarly known in the lower animals; and three stages are observable. At first, there is a discharge, chiefly watery, from the nose, with irritation of the nasal and neighbouring membranes; secondly, in two or three days there is a copious discharge of thick yellow mucus, and the membranes become slightly inflamed; there is irritation of the larynx and trachea, with fulness and a tendency to swelling, feverishness, and sonorous cough. Soreness of the throat is often present, and the lungs frequently become involved. In the third stage, usually most marked where the treatment has been neglected, the animal apparently regains health and spirits, but the cough, though milder, continues; an evil which should anxiously be guarded against. The nasal discharge also continues, and sometimes terminates in *glanders*. The complaint, as it regards the horse, requires nothing more than a few days' confinement in a stable of mean temperature, from 50° to 60° Fahr., warm clothing, bran-mashes, instead of corn, with a little laxative and diuretic medicine. If the parts about the throat are much involved, an epispastic should be applied. If the constitutional symptoms run high, venesection should be employed, and the sooner the better. In combating the third stage, a rowel or seton may be made under the jaw; the bowels should be kept free, exercise steady, and by and by tonics, as sulphate of iron.

Influenza.

Epidemic Catarrh, Influenza, the Distemper of *Horses* and *Dogs*. This very prevalent disorder is, we conceive, not infectious, but epidemic; and different epidemics exhibit characters as diverse as it is possible to conceive. Consisting essentially of the train of symptoms so well known as catarrh, with the addition of fever, more like the product of an atmospheric poison than any thing else, the symptoms are sometimes those of high inflammatory diathesis, sometimes those of the most complete depression and exhaustion. Hence, the most accurate description of one epidemic is quite inapplicable to another, and even the individual cases differ, though partaking of the general type. This being true of the symptoms, there is a corresponding variety in the treatment and probable result. We shall now make a few remarks on cases at the opposite limits of the scale, and the reader will readily understand the intervening varieties. Influenza, with inflammatory diathesis, comes on like a severe attack of common catarrh, the lining membrane of the nose being highly irritable, with a distillation of watery fluid: the irritation rapidly spreads to the frontal sinuses, the eye and throat, with oppression, and failure of appetite. A thick discharge of the watery fluid soon takes place, the parts about the throat and windpipe become highly irritable, swallowing difficult, and the food is quidded, and even water swallowed with difficulty; the cough is very troublesome; the pulse rapid, and the fever high. These symptoms would run rapidly to a fatal termination, and blood-letting is clearly the best remedy. The blood is very sizy, the venesection may require to be repeated, and the other parts of the antiphlogistic regimen must be employed. But at other times the attending fever is of the very opposite character, amounting almost to putrid fever, when the visitation goes under the name of *malignant* epidemic. Debility, and tendency to sinking, here form the type of the attack. From the very commencement, the poor animal staggers in his gait, and can scarcely stand; he refuses food, and is deprived of all energy; the pulse is rapid, small, and weak, while the catarrhal symptoms are still conspicuous. Even at the commencement, there is scarcely room for venesection, and yet the tendency to inflammation is manifest, and not only in the respiratory organs, but also in other parts. Here the practice must be the reverse of that above alluded to: refrigerants, anodynes, tonics, saltpetre, sweet spirits of nitre, camphor, laudanum, and wine must be had recourse to, with hand-rubbing, wisping, judicious ventilation, clothing, and placing in a loose box. These are descriptions of extreme cases, and the vast majority met with in practice lie between them. Sometimes an early and moderate bleeding is all that is required. The tendency to sinking appears to be thus diminished; and sometimes no venesection is required. The complaint is apt to be tedious, and also to relapse; so that the considerations which would recommend care after common catarrh, are doubly cogent in reference to influenza. We have stated that this is the distemper of the horse: it is also the distemper of Dogs, in which it is apt to be severe, accompanied with a staggering gait, and delirium from affection of the brain. In milder cases, it forms the snifters of various animals.

Under the general term Inflammation of the Lungs, several very distinct affections are included. The bronchiæ are lined with mucous membrane to the minutest cells; the entire organs—all the lobes—are included in the lining membrane, the pleura, which also covers the whole internal cavity of the chest; and there is finally the parenchymatous substance. Hence bronchitis, pleurisy, and pneumonia, though all in a general way, inflammation of the lungs, and having many things common, yet differ widely in symptoms, history, and treatment. They are all in the highest degree dangerous, are marked by symptoms of high inflammatory fever, and require prompt observance of the antiphlogistic regimen. A tendency to Bronchitis, and often more than a tendency, is witnessed in *catarrh*, and still more in influenza, and it also shows itself as an original idiopathic affection. The irritation and soreness are considerable, the natural secretion is apt to be greatly augmented in quantity and vitiated in quality, becoming viscid and grumous, and suffocation and death may be the consequence of the fusion into the air-cells. **Pleurisy**, again, is apt to at- ck the serous membrane, from sudden chills and other uses; the inflammation speedily proving a great check the breathing. Serous effusion is usually the conse- ence, whereby the play of the lung is impeded, and ay be arrested, and lymph effused, whereby dangerous lhesions are produced. **Pneumonia**, again, with some- hat of the same local symptoms, extends to the disor- anization of the proper substance of the lungs, loading em with effusion, and hepatizing them. These dis- ases, though distinct in origin and nature, are apt to be ombined in progress, and hence the hazard is augmented. leeding in large quantities at first, refrigerants, laxatives, datives, blistering, and setons, are the appropriate reme- es. As bronchitis advances, care must be taken not to low the strength to sink too much. **Chronic Cough** is sequel of the foregoing inflammatory diseases, and of hers of the lungs and wind-pipe, as has been mentioned. is common, and may often appear innocuous, but should ways be regarded with suspicion; the animals suffering der it should be watched, and the bowels kept easy. Boil- l turnips, carrots, barley, and bran mashes form useful eding.

Consumption affects cattle, sheep, and swine, more fre- ently than horses, and the young rather than the old. It ises from neglect, cold, and exposure in damp unpro- cted situations, and is very insidious in its attack and pro- ess. The animal becomes thin, the coat staring, the in appearing as if glued to the ribs; obstinate cough su- rvenes; discharge is frequent from the nose, and granu- r swelling appears about the neck. On dissection the ngs are studded with tubercles. Ulcers in the lungs, *micæ*, may be numerous, and the mesenteric glands are equently implicated and enlarged. The mesenteric ar- ry, too, is often enlarged, especially in the ass; and with- it are found a number of worms, the **Strongylus** and **ilaria**. It is in the early stage alone of the complaint, at any thing can be done; and the prospect of cure is t faint.

Glanders and **Farcy** are usually regarded as the most portant diseases to which the horse is subject; (the ule and ass are also liable;) but every account with hich we are acquainted is nevertheless unsatisfactory, and ore calculated to puzzle and perplex, than to enlighten d satisfy. One author mentions that no fewer than sixty uses of the complaint have been enumerated; whence may safely be concluded that the true one was yet to be und. The full elucidation of the subject would require ore space than we can here allow. Professor Dupuy, his celebrated work on the subject,[1] rendered good ser- ce when he so ably and irrefragably established that in is disease (for all are agreed that the two named above e only modifications) there occurs the development of numerable tubercles;—whether in one particular tissue, the mucous, or in several, has not hitherto been deter- ned. To these minute tubercles we should ascribe the gin of the nasal affection, as well as of the farcy-buds; e absorbents in the former, as well as in the latter affec- n, being speedily implicated. At first they are very all. Under certain circumstances they may lie dor- nt: or, on the contrary, they may proceed rapidly to thsome maturation, when various parts of the frame come crowded and contaminated with them, to the struction of life. It is a domestic disease, unknown ong the hordes of wild horses; of a scrofulous charac- , unheard of in climes where struma is unknown; and starvation and filth, because it seldom or never origi- tes in a well-ordered stable, but is ever found rife where e horses are over-worked, ill-fed, and neglected, and, worse than all, kept in an Augean pest-house. That such combination of circumstances may induce tuberculous complaints, the history of many familiar diseases too clearly demonstrates. The matured matter of these tubercles is decidedly contagious, and thus may the disorder be inoculated and propagated in a thousand ways; and it may also, as held by high authorities, have still more frequently a spontaneous origin. There is nothing inconceivable in the idea that this, like other tuberculous complaints, may, in its early stage, and under favouring circumstances, lie, or be kept latent and innocuous; whilst if advanced to a certain point, it becomes irresistible, and defies all the powers of art. Hence the distinction into *chronic* and *acute* glanders.

The disease usually attracts attention only when the tubercles are advancing to maturity. *Farcy-buds*, small tumors, are now seen in various situations, as on the legs, or inside of the thigh, under the collar bone, in the head, neck, or in the axilla, produced apparently from over-exertion or exposure. They are touched with the cautery, tonics are prescribed, (sulphate of copper, zinc, or iron); every thing in the stable obnoxious to health, is removed; the animal gets full diet, plenty of air and exercise; the disease is arrested, and a cure may be effected. When the disorder commences, as commonly, in the nasal cavity, the discharge is successively watery, gluey, pustular. When inspected, the surface being studded with small ulcerating tubercles, has a marked and peculiar aspect, not uniform and continuous, but irregular and angry, from the number of minute irritable ulcers, with deep and well-marked margins. Under favouring circumstances, these spread fast; all the nasal cavities are soon involved; the lymphatic glands under the jaw participate; tubercles develope themselves in the lungs, usually the prelude of death; the horse loses flesh; he falls from his meat; cough succeeds; strength fails; the discharge from the nose becomes purulent and most offensive; and the emaciated loathsome animal must at length be relieved from his misery. Whenever the disease appears among a sound stud, the infected animal should instantly be removed, and every part of the stall, stable, and its furniture must undergo a complete purification; but the glandered horse, well fed, lodged, and groomed, will often work for years, and improve upon it. Such animals are sources of danger to other horses, also to their attendants, who may be glandered by them; but isolated, they may be profitable to their owners, and not burdensome to themselves. Simple discharges of matter from the nostrils must not be mistaken for glanders.

Hydrothorax.

Water of the Chest, as stated above, is an occasional consequence of Pleurisy, which, under the circumstances, requires time and great care ere it can be remedied. Often, in more chronic cases, pain and symptoms of inflammation are not detected. Effusion, however, steals on in the cavity, and the lungs become oppressed. The chest when struck, now returns a dead, dull sound, and not the sonorous tone it emits when the healthy lung is in immediate juxtaposition. Diuretics, laxatives with mercury, tonics, and repeated blistering, are the appropriate remedies. It is for such cases that **Paracentisis** is performed, by which the watery effusion is evacuated, and the lung left free. This operation, however, is often little better than a forlorn hope. The operation is very easily performed. An opening is made between the eighth and ninth ribs, near the anterior edge of the ninth, and not far from the sternal extremity. The trochar and canula are here to be introduced, and the stream flows apace. Caution however must be exercised, in arriving at a correct diagnosis; for we have known the animal expire in the hands of the operator, from air rushing in upon the

Paracentisis.

[1] De l'Affection Tuberculeuse, &c. Paris, 1817.

healthy lung, instead of water flowing out and relieving the oppressed one, so causing instant destruction.

Plethora.

The Diseases of the Heart and Blood-Vessels have not received that attention in veterinary science which their importance claims. As throwing light upon some of them, and on pathology generally, we shall here introduce a few remarks on Plethora. When the supply of food is greater than the exigencies of the system require, an animal usually becomes fat, but still may be tolerably healthy. When, however, a sudden change is made from poor to rich feeding, not fatness but plethora may be the consequence; more blood is formed than the system can easily dispose of, and it becomes oppressed. This effect is often witnessed in cattle and sheep, which, after indulging for a time in luxuriant pastures, take what is called a shot of Blood. All at once they become very ill; some part of the body swells, becomes puffy, as if containing air, and in two or three hours the animal is dead, from the *Quarter-evil,* already described. Upon dissection a large quantity of black and decomposed blood is found in the cellular membrane which during life was distended. The horse seldom suffers in this way; but in him plethora creates a strong disposition to inflammation of the eyes, feet, and lungs, and sometimes to an eruption which is called a *Surfeit,* or the *Nettle-rash.* The hair falls off in patches, and the skin is raw and pimpled. There is also a tendency to *grease,* and to what has been designated a weed, or *Shot of grease,* in the heavy draught breed. One of the legs, generally a hind one, suddenly swells; the animal becomes lame; there is pain in the inside of the thigh, increased upon pressure; and fever supervenes. The disease bears a close resemblance to the *Phlegmasia dolens* of our species, and the leg often becomes as thick as the thigh. We consider it a disease of the absorbents; these vessels enlarging to the size of a quill, and having their vasa vasorum highly injected. We have seen it occur chiefly during continued rest after hard work and exposure to weather, in animals which were highly fed. The best treatment is large bloodletting, scarifying the limb, fomenting, and applying hay, straw, or flannel bandages, with purgatives and diuretics. The pressure of a bandage will expedite the reduction of the part to its natural dimensions.

Carditis.

Some of the diseases of the sanguiferous system are acute, others chronic. Inflammation may attack the heart, and is always most dangerous; the symptomatic fever runs high, and is generally remarkable for the bounding velocity of the pulse. Venesection must be alike prompt and free, and the other parts of the antiphlogistic regimen in keeping. When pleurisy exists, the pericardium cannot well escape, and the latter membrane may be the origin of the mischief. In either case the Pericarditis is apt to terminate in *dropsy* of the membrane, in one case of which we found not less than four pounds of serum. *Enlargement* of one or other of the cavities is by no means uncommon, and the valves are often *ossified.* *Aneurism* of the great arteries occurs, but is very rare. These affections are more frequent in cattle than in the horse; and not unfrequently we have witnessed some foreign body, as a needle, work its way into the heart, and destroy life.

Thrombus.

Inflammation of jugular.

The only other complaints belonging to this section we shall mention, are diseases which arise from *phlebotomy.* The first of these, though it may alarm the inexperienced, is very trifling. It is a globular swelling, *Thrombus,* sometimes as large as the fist, arising immediately around the newly-made incision. The filtrating of the blood from the vein into the cellular membrane, which is the cause of the disease, is rarely very copious. Gentle pressure may be used at first, and should be maintained with a well-applied sponge and bandage, kept cool with cold lotion. Occasionally there is *inflammation of the jugular* from bleeding, and more rarely, of the plate and saphena vein. The cause is usually referred to the use of a foul fleam or lancet, or from allowing hairs or other foreign bodies to interfere with the accurate adjustment of the edges of the wound. The first appearance indicative of the disease, is a separation of the cut edges of the integuments, which become red and somewhat inverted. Suppuration soon follows, and the surrounding skin appears tumified, tight, and hard, and the vein itself above the orifice, feels like a hard cord. After this the swelling of the neck increases, accompanied with extreme tenderness; and now there is constitutional irritation, with tendency to inflammatory fever. If, under these circumstances, the animal be not relieved, the head becomes swollen on one side, the sensorium disturbed, and death is sometimes, though seldom, the consequence. The mischief is supposed to arise from the inflammation spreading from the surface to the interior coat of the vein; and the disease in the neck does not proceed towards the heart, as in man, but in the opposite direction. In the first stage we must try to relieve by evaporating lotions, or by fomentations. If these fail, and as soon as the disease begins to spread in the vein, the appropriate remedy is to touch the spot with the actual cautery, simply to sear the lips of the wound, and apply a blister over it, which may be repeated. Purgatives in full doses must be administered, and the neck as much as possible, kept steady and upright.

Connected with the circulating system, we should not omit to state, that small parasites, popularly called worms, are sometimes found in the blood-vessels, and other parts. This is true in man, and still more in the lower animals. We allude chiefly to the *strongylus* and *filaria,* which are found chiefly in the aorta and cœliac plexus. Allusion has already been made to them under phthisis; and it is one of the filaria that is found in the aqueous humour of the eye of horses in the East Indies. They are accused of appearing in some of the viscera, and there causing disease; as, for example, in the bronchiæ. In these cases turpentine should be administered by inhalation and the mouth. We once, whilst castrating a colt, met with a strongylus in the spermatic vessels. The subject is too extensive to be prosecuted here.

The Brain and Nerves, as may be well supposed, present an interesting, if not a very numerous group of diseases. We commence with Fits of various kinds; and this the more willingly, as we are not satisfied that their pathology has very satisfactorily been ascertained. Swooning Fits appear in horses and dogs. The horse staggers, swings from side to side, lies on the pole, stops and falls, or falls running. The fit probably arises from accumulation of blood in the head; it is most common in hot weather, going up hill; and some animals are very liable to it. Whenever the horse shews any tendency to giddiness, he should be pulled up, and so may recover in an instant. Before proceeding, see that the windpipe be free and the bearing rein slack. Should the horse fall, remove the harness, assist him to rise, and if water be at hand, give him a few mouthfuls. This attack, in popular language, is a *Megrim,* an appellation which should give place to that of Vertigo, or *Giddiness.* There are other and more aggravated forms of the affection, proceeding to what is regarded Epilepsy, or the *Falling-sickness.* In these cases the horse rears up and falls suddenly, or he reels about and then falls; the muscles of the eye are affected with spasm, so that this organ is greatly distorted; the breathing is often disturbed, and sometimes there is violent motion of the legs. The duration of the fit varies from a few minutes to several hours. "He," says Mr Youatt, "who values his own safety, or the lives of his family, will cease to use an epileptic horse." The late Dr Gregory had his arm broken from a horse being attacked with this disease. If the horse is plethoric, he should be bled. The bowels should be kept open, and e feeding be moderate. Setons to the neck should also tried. **Apoplexy** is a disease to which the horse is t very subject. Sometimes the stroke is sudden, and the e severe; but more commonly some warning is given. e animal will be seen with his head low, or supported ainst the manger; he staggers as he stands, and if moved, ears as if he would fall; his sight and hearing are af- ted. He will continue in this state for several, perhaps elve hours. He then falls, grinds his teeth, with eyes en, protruded, and fixed, the pupil dilated, and twitch- s about the frame; he is unable to swallow, the drink eturned by the nostril or the mouth, and the dung often ded involuntarily; the twitchings increase to convul- ns, and death speedily closes the scene. The treatment he most copious bleeding, with the other parts of the iphlogistic treatment.

The frightful disease of **Mad Staggers** is seen in the rse, ox, and sheep. It occurs in plethoric subjects after at exertion, exposure to the meridian sun, and high ding, though the distension of the stomach has not a pri- ry share in its production. The first stage is that of ggish circulation and oppressed brain. The animal nds with his head thrust against some hard body, his e closed, and he yawns, doses, and sleeps till he ac- lly falls down, sometimes backwards, in his stall. This rtles him, and he rises hastily, but soon relapses. The se is slow, breathing sometimes stertorous, the appetite paired, and the animal will dose with the morsel in his uth. These lethargic symptoms may continue several s, and may at last end fatally, or they may be succeed- by wild and furious delirium. The pulse now rises, piration quickens, the countenance becomes animated, conjunctiva flushed. Fits of delirium appear, the rse dashes himself furiously about, throws himself down, s in temporary insensibility, suddenly rises, again be- nes convulsed, and again relapses into stupor. Approach such an animal is highly dangerous; for he will rear, eel round upon his hind legs, and fall back with a vio- ice which threatens instant destruction. These convul- e agonies may continue for hours, before death closes the ne. On dissection the brain is found turgid with blood, d water occasionally in the ventricles. Cattle and sheep, these animals it is the *Louping-ill*), when attacked, mble, fall down, and subsequently roll and toss about: ox gores at every thing within its reach. The treat- nt must be most active. The bleeding should be push- to faintness, and the more rapid the evacuation the bet- . The same energy should be employed in the other rts of the antiphlogistic regimen.

Water in the Brain, *Dropsy in the Brain, Sturdy, raggles, Turn-sick, Gid, Giddiness.* This disease is rare the horse, not unfrequent in cattle, dogs, and swine, and ry common in sheep. The disease is sometimes acute, t more frequently chronic, occasionally congenital, when ny ounces of fluid are found in the ventricles. Young ep and hogs are most liable to Sturdy. At first the ani- l detaches itself from the rest of the flock, and appears dull l stupid; by and by it goes round about, as if giddy, and length appears blind, in which state it may long continue, l yet recover. The disease depends upon the effusion of um, either on the surface of the brain, or into the ventricles, upon the spontaneous growth of hydatids within the skull. e remedies which have been proposed, are the making a perforation into some part of the cranium, and amongst ers, through the nose and cribriform plate into the vity; and in those cases where the serum or hydatids are s reached, no doubt immediate benefit may result. out one case in three has been thus restored. The datids may occur in any part, and careful examination on surface sometimes shews the exact locality, so that the spot may be trepanned. In cases where their effects cannot be detected, it would be folly to proceed farther. Blisters and setons have been proposed, and laxatives should be given; and if these fail, the animal should be killed, as the disease does not injure the mutton. **Palsy** also occurs in the domestic animals, and is common in the dog. In the horse it is sometimes idiopathic, but occurs more frequently in the hind legs, from severe injury of the spine. If the disease is slight, epispastics, with friction, may in time be useful; if aggravated, the case is hopeless. **Tumors of the Brain** are frequently met with on dissection, and precede and probably produce some of the diseases of the head. Their existence, however, can only be suspected, and art has no control over them.

Veterinary Science.

Palsy.

Tumors.

Hydrophobia.

Our views respecting the highly interesting disease of **Rabies**, or **Canine Madness**, are not a little peculiar; but being the result of considerable observation, and leading, as we conceive, to most important and beneficial results, we will neither conceal nor compromise our decided convictions. We hold, then, that rabies is essentially an inflammatory affection, attacking peculiarly the mucous membrane of the nose, and extending thence through the cribriform plate of the ethmoid bones, to the anterior part of the brain, so giving rise to derangement of the nervous system, as a necessary consequence: this train of symptoms, we consider, constitutes mainly, if not wholly, the essence of an occasional epidemic, not unlike some forms of influenza or epizootie; and the bite of a rabid animal is not, to another so bitten, the exciting cause of the disease, but merely an accidental concomitant in the prevailing disorder; and the disease, hydrophobia, produced in man, is not the result of any poison introduced into his system, but merely the melancholy, and often fatal result of panic fear, and of the disordered state of the imagination. Those who are acquainted with the effects of sympathy, and imitation, and panic, in the production of nervous disorders, will readily apprehend our meaning; and if our view be correct, the immense importance of disabusing the public mind on the subject is apparent. This is a task which we hope one day to accomplish. But in the mean while, considering the vast responsibility of promulgating these views, without the utmost certainty as to their truth, we shall not press them; nay, we shall, to any greater extent, withhold them at present, and shall now do all the justice our limits allow, to the elucidation of the prevailing, and what is generally considered, the established pathology and history of the complaint.

It is generally alleged, that the complaint arises spontaneously only in the canine and feline species of animals, including the dog, fox, wolf, and the domestic cat, and that from them it is readily communicated to others, as to horses, cows, sheep, and man. It is frequently stated, that these last have not the power of communicating the complaint to others; but Mr Youatt mentions, "that several farriers have lost their lives from being bitten or scratched in the act of administering medicine to the rabid horse;" and Magendie and Breschet have taken the saliva of a man who was labouring under hydrophobia, and have therewith inoculated healthy dogs, which, they assert, became rabid, and bit other dogs, so spreading the contagion. Though the disease has received its name from the horror of water exhibited by man, yet the symptom seems confined to him; rabid dogs lap freely, and sheep affected with the disease are rather greedy of water. It is a great mistake to suppose that every rabid dog must be wild and furious; on the contrary, his faculties are not particularly disturbed; there is no want of his usual sense, but great irritability; for a time he knows his master's voice, and obeys him. The early symptoms in *Dogs* are usually some peculiarity of manner, and some strange departure from their usual habits. In many instances the peculiarity consists in a disposition to pick up straws, and other small objects. Others keep licking another dog, or cold iron, or stones; and there is often a strong antipathy to strange dogs. As the disease advances, they bite those dogs with which they are associated, and lastly the persons round them, though this only in a moment of irritation; there is also a peculiar change of the voice. In the *Horse* the symptoms are such as the following. The animal will go to work apparently well; all at once he will stop, tremble, heave, paw, stagger, and fall. Almost immediately he will rise, draw his load a little farther, again stop, look about him, and again fall. The progress of the disease is rapid. The animal kicks and plunges in the most violent manner, often attempts to seize and bite other horses and the attendants, and will level to the ground every thing before him, himself sweating, snorting, and foaming amid the ruins; palsy of the hind legs is apt to supervene, the thirst is excessive, and the act of swallowing appaparently difficult. The disease rarely extends beyond the third day. On dissection, there is usually found inflammation at the back part of the mouth and nose, and at the top of the windpipe, the origin of the spinal cord, and frequently in other places. Dogs are much more susceptible of the disease than man; and thus of twelve dogs and four men bitten by the same mad dog, every one of the dogs has died of the disease, while the four men escaped. The interval between the infliction of the wound and the invasion of the symptoms varies considerably; both in man and the horse, the mean average is from three to eight weeks. As to the treatment, we would first of all state frankly, that as to cure after the disease has fairly manifested itself, none is recorded. Hence the importance of prevention, and that mainly by the speedy and complete excision of the wounded parts. At the moment the animal is bitten, no time should be lost in endeavouring to get rid of the poison. Free washing may do something, and after this a firm compress between the wound and the heart, till a veterinarian, or some competent person, be procured, who should excise freely, and apply caustic. Copious venesection has proved the most soothing remedy; and with a hint from the experience of Magendie we must close. This physiologist, knowing the influence of largely substituting water for blood in the circulating system, tried the experiment in a mad dog which was in a furious state, and which instantly became tranquil, and so continued for five hours. Again, he injected one pint of water at 100° Fahr. into the vein of a man's arm; directly the patient, from being highly rabid, became tranquil, and the pulse fell from 150 to 80 in a minute, the convulsive motions ceased, he drank water without difficulty, and continued to improve till the fifth day. In another case. death followed as in this; but at the moment of the experiment, there was a great and sudden change for the better. The patient lived eight days after the injection, and died, possibly from another complaint. In attempting this treatment, the veterinarian requires unusual dexterity, as well as caution.

Tetanus.

Tetanus. *Lock-jaw* is another of the most melancholy diseases which can be witnessed. It is common in the horse, and occurs also in the ox, sheep, and dog. It proceeds from two causes, the most common being the irritation of a punctured wound in some tendinous part, as the foot, (which may give no kind of trouble,) or from *docking* or *nicking*, and also spontaneously, especially in climates warmer than our own. The symptoms of the complaint soon discover themselves. The muscles of the jaw, as expressed in the synonym, are early affected, forming *trismus;* and the other voluntary ones are soon implicated, as those of the neck, spine, and extremities. The animal does not feed as usual, and appears unwell; he drops his food and gulps water. Saliva drops from his mouth, and the jaws are found to be stiff; even his head cannot be turned, the eye squints, and the *haw, membrana nictitans,* is drawn into the socket; the back and loin become stiff, the tail erect, and the extremities singularl fixed, " like the legs of a stool;" the pulse at the com mencement is not affected, but soon gets quick and irregu lar; the breathing becomes laborious, the countenanc wild, and expressive of great agony; the poor animal ma die in one or two days, or it may be nine or ten days be fore he is exhausted. The rule of practice is to look f the wound which has preceded the disease, and if there b irritation, to relieve it. For the constitutional symptom large bleeding is the most powerful remedy, and injectin water into the veins, as noticed under rabies, would be we worth a trial. This will promote the operation of physi which in the estimation of many is the chief remedy. drachm of croton seed, and six drachms of aloes, may b administered, and repeated the following day, the bowe being torpid. Blisters and opium have been extensive used, with the appearance of success. In the few cas where life is spared, great care is necessary during the pr tracted convalescence.

Neuro- omy.

Neurotomy is the cutting of a nerve which supplies part labouring under painful disease, for the purpose easing or removing that pain. High expectations were or ginally entertained of the value of the operation; a though many have been disappointed, yet it frequent proves highly useful. Mr Sewell, its respected proposer, h operated upon more than five hundred cases, and in eig out of ten, with marked success. The fore-feet are pec liarly liable to accident and disease, and the operation h been very much confined to them. The structure of t parts greatly favours this success, for the muscles whi move the feet are situate high up the leg, and their nerv need not be interfered with, as it is cutting the nerve sensation which affords the benefit. The practice was o ginally proposed for horses incurably lame, and for cases th would not admit of relief by any other means, and to the alone it should be restricted. It is applicable to any ki of chronic lameness about the feet or coronet, except p mice feet, and succeeds best where there is an alteration the form and texture of the hoof; and in anchylosis often yields great benefit. If inflammation or ulceration present, the operation must at all events be postpone since it would aggravate these states. The operation not difficult. The horse being cast and secured, an in sion about two inches long is to be made upon the side the large pastern bone, in the direction of the large paste nerve; the trunk of the nerve is to be laid bare, avoidi the artery which lies anteriorly, and about one inch of it is be cut out; the excision is to be made on both sides, a in both legs, if both are diseased; the wound to be heal by the first intention.

Stringh

Stringhalt is more a blemish than a disease, thoug is very unpleasant to the rider. It is a convulsive kind action in the muscles of the hind-leg, supposed owing irregularity of nervous influence. Neither its precise s nor nature is accurately known, and dissection has fai to throw any light upon it. It is most conspicuous wl the animal commences exercise, and in a short time greatly subsides. Any method of cure is yet unknown.

Disease the eye.

The **Diseases of the Eye** are highly important, slightest blemish interfering with the usefulness and va of the animal; and, though not numerous, they have e been found most untractable, and regarded as reproache the science. Criticising the labours of the many auth who have so ably illustrated our art, is what we would sc pulously avoid; but, on the present occasion, a sense duty constrains us to warn the student generally aga many of the views and statements which have been p mulgated; no where have we seen more loose observati more erroneous pathology. The organ is most delicate, anatomy most minute; and it is upon an accurate acqua ce with this, both in health and disease, that practice can ne be based. To one ignorant here, all is obscure; his atment must be undecided, and of course unsatisfactory. ie diseases of the organ are, to a remarkable extent, the ult of the domesticity to which we have subjected the ver animals, and especially the horse; in our stables they ever forcing themselves upon our notice, while so long he is running wild, and breathing the untainted air, they never seen, and in the other animals, with the excep- n of the dog, they are but rarely witnessed.

The front of the ball of the eye, and the inner surface of e eyelids, are covered with a membrane, the conjunctiva, st of whose blood-vessels are colourless. This membrane he seat of common OPHTHALMIA, in common speech, of *lamed eye*. Whatever irritates, inflames; and hence we how the application of any foreign body, a few particles sand, or a hair, may produce ophthalmia. This is the ly disease of the eye which has been noted in cattle, and sing solely from the cause now mentioned. Sometimes se bodies are actually impacted into the membrane; a aw or hay seed may be so fixed, that all the efforts of animal may fail in removing it; the eye becomes red l troublesome, and hence the importance, in all cases, of refully examining the organ, and satisfying ourselves re is no cause of external irritation present. It is not, wever, to be supposed that these foreign bodies are the e cause of ophthalmia in the horse. From the state the constitution, exposure to weather, and often the ntamination of a filthy stable, idiopathic ophthalmia ses. The conjunctiva and its offshoots, towards the hrymal gland, and elsewhere, are implicated. It is found iversally red and inflamed, the eye is very sensitive to ht, it waters much, and there is pain. This may excite neral fever, or it may not; and this is always an impor- nt element. It may continue a long while, and prove ublesome without the deeper parts of the organ being plicated, or they may be involved; and it may be *acute*, th a tendency to high inflammatory symptoms, or it may *chronic*, where there is the very opposite, namely, weak- ss and debility in the parts, and in the frame; this latter te is apt to be quite as tedious, though not so painful as former. This distinction should never be forgotten in ctice. When called to treat a case of this common oph- lmia, after ascertaining there is no irritation from a fo- gn body, we are first to examine the state of the stable, at the air is not impure, or too hot. If a horse has viously had inflammation of the eye, this attack may nothing more than a local affection of the vessels, and ssibly a wash, or rather an injection, of some simple col- ium,[1] once or twice a-day, is all that is required. These ternal applications should not be used too strong. Bran shes should be substituted for corn, and a laxative pre- ribed; the horse should not be exposed to the inclemency the weather, and the light in the stable should be derated. All this may by some be regarded unnecessary d troublesome; but so long as it is a fact that one attack apt to induce another, and that these in the long-run de- oy the sight, it is the greatest folly not to meet, and if ssible remove at once, the present ailment, and the fu- re tendency. If the symptoms do not speedily yield to is treatment, we must determine whether there is inflam- atory diathesis, or chronic debility; the condition of the imal, of the pulse, of the eye, are all to be considered, and these show that mischief threatens, the antiphlogistic re- men in all its parts is to be energetically applied, and the e is to be protected from the stimulus of light; fo- entations and injections are carefully to be applied, and tons introduced. These directions are given under the supposition we have to deal with acute ophthalmia. When it is chronic, this treatment would be detrimental, both to the disease and the constitution. In the chronic form, the local treatment generally consists in stimulating collyria and setons, and the constitutional, instead of being lowering, must be strengthening. A peculiar, and not unfrequent cause of irritation we must not omit, which consists in the inversion of the lower eyelid, whereby the eyelashes constantly play upon the eye-ball, and thereby inflame it, constituting the disease called TRICHIASIS. This complaint we have often witnessed in dogs and cattle, but seldom or never in the horse. Pulling out the eye-lashes affords but a temporary relief, as they soon grow again in a wrong position. A part of the loose skin of the eye-lid must itself be removed, by pinching up a portion, and removing it with scissors, and healing with stitches; after this, when the parts heal, the cilia are found restored to their proper position. It is in this connection that NEBULÆ and SPECKS in the cornea are to be considered; the former being more superficial, the latter dipping more deeply into the substance of the part. Directly in the sphere of vision, these of course impede it, and cause obscurity of vision. Even here, we must proceed gently. These blemishes are the pure consequences of inflammation, and this subdued, their tendency is to disappear. Time and nature will do much; and the duty of the practitioner consists in helping forward the salutary process where necessary, by gently stimulating washes, whilst irritating powders should be avoided, especially in dogs. OPEN ULCERS frequently occur in the cornea, and are always to be viewed with alarm, as they may speedily cut deep. They should be delicately touched with a fine point of lunar caustic, by which the morbid action is usually changed.

Trichiasis.

Nebulæ.

Specific ophthalmia.

As the conjunctiva is liable to acute inflammation, so is it with the internal membranes, the choroid, iris, &c. It seldom, however, happens in the lower animals, that an opportunity is afforded of examining these parts under disease separately; and hence, what has been called INFLAMMATION OF THE INTERNAL EYE, SPECIFIC INFLAMMATION, AND MOON BLINDNESS, may be considered as an inflammation of the whole internal parts of the eye. That there is any thing *specific* about this complaint, we do not believe, although high authorities have proceeded so far as to distinguish it as the specific gouty opthalmia. All that we are to learn from this is, that the constitution is often at fault, and must be regulated; that there is an inflammatory diathesis, and that every error in diet or treatment tells upon the weakened part. This inflammation is apt to move from one eye to another; and overcome once, to return again and again, (hence its name moon blindness,) till the sight is entirely lost; all which, we believe, is owing mainly to two causes already hinted at; namely, that due care is not taken of the organ in early attacks, and in endeavouring to restore the constitution to sound general health. These views are to be our guides in the treatment; and if this required to be decided in the opthalmia already dwelt upon, still more is it necessary in that now under consideration. As to the symptoms, this internal inflammation may exist without the external parts participating, but usually they are soon involved. One symptom very pathognomatic we must also add; it is a whitish opaque state of the cornea, which supervenes in a few hours, completely obscuring vision, and interfering with our perception of what is going on within the eye. This is not to be viewed as a distinct disease of the cornea, as is often supposed, but merely the result of the fulness and pressure of the parts behind; and were that once relieved, the cornea would immediately regain its transparency. As to treatment, we have scarcely any thing to add. The sight, and the whole value of the animal is at stake, and what is done, must be done promptly and thoroughly, and the animal should not be removed from the sick list till he is in sound wholesome condition, sound in lith and limb, when he would be as little liable to future attacks as others.

---

[1] COLLYRIA. *Cooling.* Sugar of lead, one drachm; opium wine, one drachm; water, two pounds. *Stimulating.* Sulph. zinci, two achms; opium wine, one drachm; water, two pounds; or nitrat. argenti, one drachm, aquæ distill. one pound.

Cataract.

CATARACT is an opacity of the lens or its membrane. It may follow as a consequence of the disease last described, when no remedy can be of any use, as the whole organ is disorganized; or it may occur as a pure idiopathic disorder, when, ere long, it will completely obstruct vision. In this form it usually appears in the dog. This complaint can only be remedied by an operation; and extraction being exceedingly difficult in the horse, all attempts to perform it should be relinquished. Couching would be more easily performed. But still the removal of the lens is so detrimental, that it is scarcely worth a trial.

Amaurosis.

GUTTA SERENA, or *Glass Eye*, when pure, is an affection of the retina, or of the brain, which fails to receive the usual impression from light. Professor Coleman had a horse which fell backwards, on one side of the head, and the opposite eye became amaurotic, probably from injury to the brain. A touch of apoplexy often produces the same effect; or it may be acute inflammation of the retina; or chronic, which may never have attracted observation. Depletion may at first be tried; and then the use of setons, attending to the general health. WORMS, the *filaria* already mentioned, (p.636,) occur in our East Indian possessions, in the aqueous humour of the eye of the horse, a curious locality, their occupancy of which is not readily accounted for. Twenty cases sometimes occur during a twelvemonth in a single cavalry stud. On puncturing the cornea, the prisoners escape.

Worms in the Eye.

Diseases of the ear.

The EAR of the dog is liable to several diseases, of which the internal and external canker are the most considerable. The former consists of irritation and ulceration of the tube, with discharge of matter, sometimes of blood, occasionally closing the ear, and producing deafness; or the ulceration may spread to the internal parts, and produce death. This chiefly occurs in water-dogs. Injections of sugar of lead, white vitriol, or nitrate of silver, are the most powerful local remedies, and the general state of health must be improved. Canker in the outside of the ear appears most frequently in smooth coated dogs: and the same kind of washes, with the decoction of oak bark and iodine ointment, are the most effective remedies. If it does not yield to these, the ear must be rounded, and the disease extirpated.

Canker.
Internal.

External.

Of the skin.

CUTANEOUS AFFECTIONS. The name SURFEIT has been given to a crop of small tumors about the size of hemp-seed or large peas, which break out suddenly over the bodies of horses, especially in spring, often beginning at the neck, and frequently disappearing as quickly as they come, being attended occasionally with itchiness. Its pathology is obscure. The digestive organs are supposed to be at fault; and poisonous herbs, a draught of cold water when heated, sudden exposure to cold and damp, calcareous balls, and worms, have been suspected. Moderate bleeding and laxatives form the surest remedies. The somewhat continued use of doses of antimony, nitre, and sulphur, have been much commended. The horse should be comfortably clad, and should receive regular exercise.

Mange.

MANGE is a very common and most loathsome disease of the domestic animals, arising from a cause the very reverse of that implied in the name of Surfeit, being the result of under-feeding, starvation, and neglect. It is in a high degree contagious; for not only contact with an infected animal, but even with the sordes from his body wherever they are found, is sufficient to produce it. While we thus state that mange is common in the lower animals, we mean nothing more than that a disease of the same general character may affect them all. It is sometimes supposed that all these are specifically the same, and that the itch in man, and the mange in the dog, are ider tical with the disease in the horse, the ox, and the shee This, however, we apprehend is carrying the matter too fa It is said the mange in cattle has been propagated to th horse, and from the horse to cattle; but it is held there no decided instance of the mange in the dog being con municated to the horse, and still less of the mange of t quadruped being communicated to man, or the itch of m to the quadruped. We may here however mention, th we have seen a herd of cattle labouring under ring-wor a modification of the complaint, and the two boys w were keeping them were infected with the same con plaint. In the *Horse*, we have noticed two varieties, t one of which is vesicular, and in this we are persua ed animalculæ abound, whilst in the other there is or simple disquamation, with oozing of ichor and falling of the hair. This variety is much the most common summer. The face, particularly round the eyes and li the sides of the neck, the withers, shoulders, axillæ, a thighs, are the parts most conspicuously manged. T grand cause we have already hinted is under-nourishme what is technically called *poverty;* but when once induce if care be not taken, it will spread widely. In stables consider it a token of want of care, and sufficient dressi When wishing to rid an animal of the complaint, or guard against its being infected, the most minute attenti must be given to its clothing and furniture, as brush combs, pails, manger, &c.: these must be purified and k uncontaminated; after this the cure with a little trouble readily effected. As to constitutional treatment, gentle la tives and alteratives should be prescribed, and the food nourishing and soft. As to local, sulphur ointment, in a of its well-known formulæ, combined occasionally with so preparation of mercury, or tar with rape-seed oil, is a sov reign remedy. In *Cattle* and *Sheep*, the ichorous matter apt to collect in the neglected hair and wool, and hence t name SCAB-MANGE, SCAB, and SCURF. In commencing t cure, these sordes must be washed off, and *salving* must most freely administered. This should be done at the fi appearance of the complaint, for when once introduced in a flock it greatly diminishes its value. It seems to spre not so much by direct contact, as from the infected ston banks, &c. which are the principal resorts of the flock. *Dogs*, the disease is obstinate, and exhibits several varieti One of them is called the *Red-mange*, in which there is particular eruption, but a general redness of the skin, whi is hot to the touch. Sulphur, sulphuric acid, chlorine, me curials, tobacco, and hellebore, are the local remedies, a laxative and alterative medicines, with abundant light fee ing, the general.

ERYSIPELAS in sheep appears in various slight modific tions, which have received different names. WILDFI it is said, generally shews itself at the beginning of wint and first attacks the breast and belly. The skin inflam and rises into blisters, containing a reddish fluid, whi escapes and forms a dark scab. The animal sometimes f vers. Venesection should be used, the skin should be was ed with a solution of sugar of lead or with lime water, a physic given, such as salts and sulphur; afterwards a fe doses of nitre. Under a somewhat severer form, it is apt spread quickly among the flock. It appears generally autumn, and does not continue above eight days at a tim although the sheep once affected are liable to a relaps The treatment is the same as in wildfire, but somewh more vigorous. MALLENDERS is the name given to scurfy and somewhat obstinate eruption on the inside the hock of the horse in the fore-leg, and SALLENDERS a similar affection in the hind one. Washing with soluti of corrosive sublimate, or with sugar of lead, or anoi ing with iodine ointment, with an occasional laxative, a diuretic, should effect a cure. SADDLE-GALLS are sor sing from the friction of the saddle, for which a strong ution of salt with tincture of myrrh is a good application, ilst attention should be paid to the padding of the sad- . The tumors which sometimes result from the pressure the saddle go by the name of Warbles; to which, when y ulcerate, the name of Sitfasts is applied, from the lous skin which adheres to their centre. Goulard water y be used to disperse the swelling; a digestive ointment l remove the sitfast, and the sore should be healed with olution of sulphate of zinc.

The well-known and unsightly disease called Grease, a morbid secretion from the cutaneous pores of the heels l neighbouring parts, of a peculiar greasy offensive tter, attended with irritation and increased vascular ion. It is most frequently seen in coach and cart horses, often also in young colts which are badly cared for; s most common in the hind feet, but occurs in all. Its in cause seems to be sudden changes in the condition the foot from dry to wet, and from heat to cold, greatly gmented, of course, by evaporation. It is seldom seen thorough-bred horses, and this probably because they well groomed. The first appearance of grease is a dry urfy state of the heel, with heat and itchiness. Swelling ceeds, with a tendency to lameness; the discharge gments in quantity, the hair begins to fall off, and pain l lameness become marked. Deep fissures are apt to come prominent symptoms, and to occur sometimes at upper portion of the fetlock; in the former case they designated Dry-cracks, in the latter Rattails, by riers. Pustules now arise, which burst, and expose at coarse granulations, which have received the name Grapes, and which, with the thickened skin, become gh and hard, almost horny. The diseased foot at this e may be thrice its natural thickness. As to treatment, evention being better than cure, we re-echo the state- nt of Professor Coleman regarding cavalry horses, that soldier deserves punishment whose horse becomes easy. In the early stage, the parts should be washed ice a day with soap and water, and a solution of sugar lead and sulphate of zinc applied; this may not be che- cally scientific, but we have found it superior to any ing else. Even in old and aggravated cases it is very effi- cious. When grapes abound, a little of the powdered c should be introduced among them, which application en supersedes the application of the actual and other uteries, as do also, more decidedly, strong washes with luted sulphuric and nitric acids. We have also found a lution of corrosive sublimate, and iodine ointment, excel- nt remedies. If the horse be strong and full of flesh, xatives should be given, followed by diuretics; if weak, nics may be added to these last. The feeding too must varied with the condition;—green meat and carrots ould be given, and mashes frequently as a substitute for rn. During convalescence exercise should be given; d bandages and pressure hasten the cure.

Warts or Angle-berries are prone to occur in the rse, and in cattle, and to be troublesome, more espe- ally in calves. They appear about the eyelids, ears, se, neck, groin, sheath, and are apt to spread. They ten require removal. Sometimes you must cast the horse, d remove them with the scissors, knife, and cautery, or ith a ligature. Escharotics, however, have great efficacy, ch as alum, blue-stone, corrosive sublimate, and some- mes arsenic. Encysted Tumors also are by no means ncommon, a kind of *Talpæ*, which may generally be re- oved by simple incision, having no decided root or adhe- on.

The domestic animals are apt to be annoyed with ver- in, which slight knowledge and attention would readily emove. In particular states of hot weather, Flies, especi- lly some species of the *Tabanidæ* are great nuisances; they will make a spirited horse unmanageable, will drive cattle from their pasture, to scamper about in a state of extreme agitation; and as to sheep, the Ettrick Shepherd says,—"The flies were at this time settled in the fold in such numbers, that we could with difficulty see each other; the heads of the sheep were swollen and black, and seemed all over a scab, the flies being settled on them like a black cloud. A few were anointed with train oil, and no sooner were they turned among the rest, than in less than a minute, not a fly was to be seen." Spirit of tar, added to the oil, renders it more efficacious; and as the fly will not face these remedies, horses and cattle should be protected. Fleas are very troublesome to dogs. Washing and combing are not without efficacy, nor tobacco-water, though it frequently poisons the dog. Mr Blaine says, "the only tolerably certain cure I know is, to make the dogs sleep on fresh yellow deal shavings." Rosin and bran may be usefully applied. Oil, however, we believe, is a specific. We have invariably found it so for Lice, so common in horses, cattle, sheep, and dogs. In horses, the prevalence of this filthy vermin shows want of dressing, although it is often connected with poverty and mange. In the slighter visitations we have invariably found, that a single dressing of olive-oil alone, will cause their disappearance from all the above-named animals, or a solution of corrosive sublimate, although this requires a little more caution. For the Tick in sheep, a mixture of tar and turpentine is a speedy and certain poison; and for the Maggot, sometimes a most fatal vermin in this quadruped, the great matter is the shepherd's watchful care; as soon as discovered, the affected part must be shaved, and spirit of turpentine, or of tar with oil, or a solution of corrosive sublimate applied.

VEVAY, a town of Switzerland, the capital of a bailiwick of the same name in the canton of Vaud. It is finely situated on the lake of Geneva, where the climate is mild, and the prospects around are of the most exciting description. In this town many English families find a retreat. There is a college, an hospital, and other benevolent institutions. Vevay has little trade, and that mostly in native productions. It contains 430 houses, with 4500 inhabitants. There are two churches, in one of which, St Martin's, are monuments to two Englishmen, Ludlow and Broughton, who had sat as judges at the trial of Charles I. and found refuge here.

VIADUCT. The contract for a brick viaduct should clearly define the site and extent of the whole of the sections; the gross amount to be paid, as well as the detail prices at which any additions or extra works are to be paid; an enumeration of the plans, sections, and drawings, which should be signed by the engineer and contractor; and, attached to the contract, the mode in which the work is to be paid for, the time for its completion, and the time the contractor is to uphold the work, together with the penalty for non-completion. It should state in a precise manner any diversions of roads or streams, the nature of the foundations, and whether the contractor is to find cofferdams, centerings, scaffolding, and all other machinery and materials. With respect to the time for completion, it will be best to divide it. If, for example, it is a viaduct of ten to twelve arches of fifty feet span, and forty feet high, in twelve months at the farthest the brick work and masonry of the abutments, piers, and wing walls, should be up to the springing of the arches. The remainder of the work may be divided into two portions of six months each, so that the whole should be complete in two years. We are well aware that such a work could be executed in much less time, but it would be at a corresponding increase of expense.

The contractor should be bound to execute the work to the satisfaction of the engineer, or whoever may be appointed by the parties for whom the viaduct is to be erected, and at all times to keep a sufficient number of men on the work, or the engineer should have power to send the requisite number. This will of course be done at the contractor's expense; and it should be expressly stated, that all materials, scaffolding, and machinery, on the spot, will be used by the engineer, and that he will provide any other materials which may be requisite, in order fully to employ his men. The number of competent foremen to be employed by the contractor should be stated; and the engineer should have power to supersede any of them for incapability or improper conduct, and in default of there being a sufficient number, to employ as many more as should be found requisite, up to the specified number. An account of the foremen and workmen employed, should be furnished to the engineer weekly, each trade being classed under a separate head, under a penalty of five pounds per week.

The contractor should be bound to enclose the whole area before commencing the work, and to comply with all local regulations and the act of parliament, if there is one, under which the work is to be done, so as to prevent all trespass on the adjoining lands, and to maintain the said fence till the works shall be completed; but if any of the adjoining land would be of use to the contractor, it should of course be procured for him, by his undertaking to pay the expenses. He should be bound to deposit any spoil earth taken out for the foundations, wherever the engineer may appoint. Any temporary roads which he may require, should be set out and made entirely at his own expense, he compensating the owners of the land. Before he commences any excavation or work for any of the abutments, piers, or wing-walls, or commences any arch, proper notice should be given to the engineer, under a penalty of not less than twenty pounds.

Should the parties for whom the viaduct is to be built, be called upon to pay any damages to the owners of the adjoining property, or to any other person, through the negligence or wilfulness of the contractor's workmen, they should reserve the power of deducting the money so paid from any sums which may be due to the contractor for the performance of the work. No subcontract, except for labour, should be allowed, without the the engineer's consent in writing. Should the contractor become bankrupt, or should he, from any other cause, cease to continue the works, the engineer should have power, after serving him with a written notice, to carry on the work himself, placing the amount of all monies expended by him, in constructing the work, to the contractor's account, and using all the materials and machinery on the ground, which should become the property of the parties for whom the viaduct is built, from the time they are brought upon their ground, till the completion of the works, and should not be removed without their consent. When materials are brought on the ground of an improper sort, or unsound, or of an inferior quality in the opinion of the engineer, the contractor should be bound to remove them forthwith, and to supply their place by others, in default of which the engineer should have power to remove them after two days' notice, without being amenable for either loss or damage in so doing. The expense of the removal, of course, should in all cases fall on the contractor.

Should the engineer discover that any part of the work is unsound, or imperfectly executed, or not performed in strict accordance with the conditions of the specification, plans, sections, or drawings, he should have power to order it to be immediately taken down and executed in a proper manner, without any extra charge whatever, and without any delay ensuing in the completion of the several parts of the work; and if the contractor should refuse or neglect to do so after proper notice, the engineer should have power to cause it to be done, charging the expenses to the contractor, and removing the materials, and then proceeding to erect the work in a proper manner.

The contractor should be bound to make any alterations, additions, or omissions in the work, on being authorized to do so by the engineer; the omissions being set off quantity for quantity against the additions, or by measurement and valuation, as may be agreed on, and the balance accounted for to either party. There should be no alterations whatever allowed, except under the signature of the engineer. The contractor should be furnished with copies of the drawings and specification, but he should be bound to see they are correct, and should also be required himself to set out the whole of the work. Should there be any buildings, trees, or other matters on the site of the works, the property in them should be secured to the parties for whom the viaduct is to be built; the contractor removing them to the nearest public road, giving a week's notice previously to his doing so, and stating the place to which they will be removed. All damage done to the works during their progress, or to the materials or implements thereon, whether arising from accident or the carelessness of the workmen, should be made good at the contractor's expense; and he should be bound, not only to execute such works as are expressly described respectively in either the specification, plans, sections, and drawings, but also such other works as may be necessarily implied, or reasonably inferred to be done; and in case of any dispute arising, the decision of the chief engineer should be considered final.

The mode and times of payment for the work, and the nature and extent of any sums which may be retained from the periodical payments, as a security for the due performance of the contract, should be clearly defined, and also the time when the retained money will be paid, which in all cases should be dependent on the engineer being perfectly

atisfied with the state of the works. It is usual to make
ne contractors of these works an allowance, when they have
large quantity of materials on the ground, as part payment;
r instance, when two million or more bricks are on the spot,
ty per cent. on their value is usually advanced; and, ge-
rally speaking, if it is seen that the contractor is proceed-
g with his work in a spirited manner, he should be en-
uraged by every reasonable assistance in the power of
e parties by whom he is employed.

The schedule of prices for extra and additional works
ould include every thing which is at all likely to be re-
ired; such as fencing, excavations, brickwork, concrete,
onework, specifying the nature and quality of the stone,
d the description of the work; such as string courses,
ping, ashlar work, imposts, cornices, caps to pilasters,
oins, &c.; the price of wrought and cast-iron work, of
lverts, drains, and ditching, specifying the size in each
se; of timber, stating the size and description; pruning
d levelling at the ends of the viaduct; piling for founda-
ons; the formation of roads; laying railways, distinguish-
g the price with blocks from those with sleepers; and all
her things which it may be necessary to order in the
urse of the work.

It is usual to take security from the contractors for these
orks. Many an excellent contractor may not be able to
d substantial sureties. In this case, his character from
s last work will form the best criterion. It is always ad-
ntageous to get a zealous, active, and substantial con-
actor, even at a higher price, for all large works.

The specification should state in a clear manner the site
the viaduct, its intended use, and what work is to be in-
ded in the contract, with any other information, so as to
able the contractor clearly to see his way. The level
ould be stated, the span, height, and form of the arches,
ether any are askew, and if so, the angle of their incli-
tion; the radius of the curve, if there is any; the nature
d quality of the principal material; and if this should be
ick, then whether there are to be stone arch quoins,
ringing courses, string course, plinth, or coping; also,
at pilasters, &c. are intended; what is to be the form of
e piers, whether they project from the face line of the
ch; what description of wing walls, and whether they are
be built plumb, or battened, or curved, and what arched
enings they may have, and if so, whether there are to be
verts to them, and also any other internal openings which
ay be intended; for instance, in railway viaducts, walls
ll be required in the abutments for the support of each line
rails; but these may be built considerably cheaper, by
htening them with arched openings, having inverts un-
rneath. In this case, the wing walls might be built
umb, and extended just far enough for the required slope
the embankment at each end. The space between the
lls, for supporting the four lines of rails, should be arched
er with nine-inch brickwork for supporting the earth and
llasting of the railway. The spandril walls should be
rpendicular, and a wall should be run, if the height re-
ires it, under each rail, extending over the arches, piers,
d abutments; the spaces between these walls being arch-
l over in a similar manner to those described above.

The form and dimensions of every part of the viaduct
ould be shown in the drawing, which should contain an
evation, plan of foundations, plan of the roadways or wa-
rways, if any; sections through the square and askew
ches and piers, the abutments and parapet walls, showing
e form of the string course, plinth, and coping; and last-
, a longitudinal section throughout the whole length of
e viaduct. The nature of the ground should be carefully
udied, before the footings of the piers and abutments are
ecided on; and if at all doubtful, concrete should be used;
it in all cases, the footings should be stipped outwards,
d carried so low as to rest on an entirely good and solid
foundation. Should there be any waterways under any of the arches, the outer course of materials of the piers on each side the water, should be laid in Roman cement, high enough to ensure their safety in this respect. The piers of askew arches may generally be lightened in the interior, and the mode of doing this should be shown in the drawing.

The spring course should if possible be of stone, not less than twenty inches thick on the face, say for an arch of fifty feet span, and rising behind, so as to form the proper skewback of the arch. These should be laid over the tops of the piers and abutments, each stone not being less than three feet six inches in the bed, each course consisting of not less than eight stones in the width of a viaduct of about twenty-eight feet broad; and no stone should be less than three feet six inches in length, dowelled and leaded to the adjoining one. If the viaduct is brick, the upper surface of the stones, at the springing of any askew arches, should be made in steps or notches, for receiving the brick-work of the arch, each step taking five courses of bricks, and being cut at right angles to the brickwork, rising behind at the proper summering for forming the skewback of the arch. The five courses of bricks agreeing with each arch stone, should all fit into a corresponding step in the springing course.

The form of arches is so much a matter of taste, that no general rules can be given without assuming some particular one. We shall therefore take a segment of a circle, a very substantial viaduct in that form having been built by Robert Stephenson, Esq. They were fifty feet span, thirty feet eight inches in length, and three feet thick. The thickness of each arch quoin was equal to five courses of bricks; and they were alternately three feet three inches, and two feet six inches in length on the soffit from the face of the arch, and rising in steps to receive the horizontal courses of the spandril walls.

Great care should be taken in giving all the arch quoins a true and perfect bed throughout each stone; and no pinning should be used in any part. The joints of the arch stones should be neatly chamfered rustic, and the faces of them fair tooled, and projecting about an inch from the brick work. The proper summering should be given to the bricks in the arch; and any irregularity of form, arising from imperfection in the laggings, workmanship, centering, or any other cause, should be removed, and immediately corrected by the contractor. The centres should in no case be struck without one week's notice to the engineer. After they are removed, the whole of the brickwork in the soffit of the arches should be carefully and neatly pointed. With respect to keeping the arches dry—a point which it has been found extremely difficult to effect, and without which the brick work soon becomes damaged—we believe that puddling, if carefully and properly done, will always succeed. Drainage by pipes through the piers has been tried, and failed. A mixture of coal tar and lime has been found to succeed, and so has coal tar alone, boiled ten or twelve hours, so as to evaporate the water and ammoniacal liquor. As, in cooling, it sets moderately hard, it must not be laid on in wet weather, and the surface of the brickwork should be clean swept previous to applying it. Leading the arches with about five pound lead is a sure preventive; but the process is expensive. The asphaltic cement is also a certain cure, but is dear compared with coal tar.

The backing should be built up to the required height, with good brickwork, well grouted. The wing walls of a railway viaduct should consist of six walls, built plumb up to the level of the crown of the arches, and extending in the direction of the railway towards the embankment at each end. They should be well bonded into the abutments, and lightened by arched openings. The top of the exterior walls should be brought to a proper level with the upper side of the arches, for receiving the string course and parapet walls. The outer walls for the sized arches we have assumed should be about three feet thick, and constructed with bricks laid in horizontal courses, properly jointed with the arch quoins. The interior walls should be eighteen inches thick.

A string course should be laid along the whole length of each front of the viaduct, projecting uniformly with the face line of the arches. No stone in this string course should be less than three feet six inches in length, neatly tooled on the exterior, with the joints made to fit close for the whole bed of the stone. The parapet walls will have a bolder and handsomer appearance, if they stand on a stone plinth, about eighteen inches high, and eight inches wide, placed upon the string course; the remaining portion of the wall being brickwork, fourteen inches thick; the courses being carefully laid parallel with picked bricks; the exterior faces of the plinth being fair tooled, and the whole of the walls throughout forming a uniform and regular line.

The coping should be of stone, the form and dimensions for which should be shown in the drawing; and no stone should be less than three feet in length, neatly jointed, and the exterior faces fair tooled or chisel-dressed, each stone being dowelled or leaded to the adjoining one. The spaces round the footings of the abutments and wing walls should be firmly rammed up with clay, if it can be procured, to the level of the ground, in courses of one foot in thickness, each layer being properly beaten before a succeeding one is put on. It will sometimes be convenient to make a new channel for water-courses, so as to bring them through a given arch of the viaduct. In this case, the old channel should not in any way be impeded, till the new channel is formed; after which, the excavation which has been taken out to form the new channel, may be used in filling up the old.

Great care should be taken in the selection of materials for the construction of these works. The bricks should be hard, sound, and well burnt; those used in the face of the work being selected of a uniform size and colour. The quarries from which the stone is to be brought, should be named, and care taken that the whole is of a good and hard quality, free from flaws of every description. The mortar should be made of lime to be named in the specification, and mixed in the manner, and in the proportions between the lime and the sand, which is known to be best for the particular kind of lime, and be thoroughly incorporated of the proper consistence. The Roman cement should be recently made, and kept from contact with the atmosphere, or any moisture. An equal quantity of good sand or road dust should be mixed with it; and no more than what is required for immediate use should be mixed, or any that has set be worked up again.

The brickwork should be laid either in English or Flemish band, as may be ordered; and in no case should any joint of mortar exceed a quarter of an inch in thickness; no broken bricks should be allowed to be used, either internally or externally, unless absolutely necessary as closers; nor should any difference be made in the exterior and interior of the work. The whole of the brickwork should be grouted at every course, and the exterior neatly pointed. All the stonework should be truly bedded, and the vertical joints cut square back for the whole bed of the stone; no pinning of any kind being allowed.

After the piers have all been brought up to the level of the springing of the arches, the contractor should fix the centering, and complete the brickwork and masonry of the three arches, and their backing next adjoining to an abutment; the wing walls and spandril walls being also carried up to the same height as the backing. When these three arches have all been completed, and properly backed, the centering may be removed from the arch nearest the abutment, and fixed in the proper place for the completion of the fourth arch. As soon as the fourth arch is completed, and backed as above, and not before, the centering may be moved from the second arch from the abutment, and fixed in the proper situation for completing the fifth arch; and so on with the rest, the centering never being removed from the two last arches which have been turned, until a third, or the one in advance of these two, has been finished. The centering used should be subject to the approval of the engineer.

The string course, plinth, parapet walls, and coping, should not be put on, until the whole of the centres have been withdrawn; and in no case should the centering be struck without orders from the engineer. If the foundations require cofferdams, the contractor should be bound to find them at his own expense. Great care should be taken that the viaduct is properly placed, so that, in the case of a railway, the outside line of rails, when laid in their uniform and proper position, shall be equidistant from, and parallel with the faces of the parapet walls; and in case the line in that particular part where the viaduct is, should be curved, this will require the most vigilant attention; also, that before the string course is laid on, every part of the brickwork is properly level, so that the eye, in running along the string course, shall not be able to detect any deviation from the given line. We have known more than one case in which a noble and handsome structure has been entirely defaced, to a professional eye, through the inattention or the incapacity of overlookers who have been entrusted with this important part of the work.

After the expense of an embankment equals that of a viaduct, there will almost always be a gain in building the latter, if an increased height is required; because the addition to the piers and abutments for this extra height, will cost much less than the additional earthwork at the base of the embankment. Let us take a case in point. In 250 yards of railway, forty-five feet high, there are required three bridges. A viaduct for this 250 yards, with fifty feet arches, would cost L.17,000; each bridge would cost L.1400, and the remaining embankment sloping 2:1, would cost L.6150, at 1s. per yard; total, L.10,650. Hence the viaduct is much the dearest method. If the height was seventy-five feet, the bridges may be taken at L.2000 each, and the remaining embankment at L.15,250; total, L.21,250, besides the extra land; while the viaduct, having only 216 cubic yards of brickwork, at L.1 for each yard additional height, after full allowance for extending the wing walls, &c., would only cost L.19,000. We may conclude, therefore, that viaducts are cheapest only at very great heights. Much of course depends on the length of lead, whether building stone can be got from an adjacent cutting, &c. The cost may however be lessened, by a judicious use of wood and iron. Several wooden viaducts have lately been constructed for railways; and in America they are largely used. A novel plan has been adopted in that country by Mr Town. (See Stephenson's Civil Engineering of North America.)

In the preceding articles in this work, the subject of arches has been so fully discussed, that nothing remains except to give a guide to practical men, how to construct the arch of equilibrium, and to shew the variation which it undergoes under different dimensions. Supposing, then, the roadway on the viaduct to be horizontal, (fig. 1, Plate CCCCC.) let KI $= y$, AQ $= h$, CI $= w$, DK $= a$, and KQ $=$ C, then

$$y = h \frac{\text{Log. of } \dfrac{w + \sqrt{w^2 - a^2}}{a}}{\text{Log. of } \dfrac{c + \sqrt{c^2 - a^2}}{a}}$$

where the denominator has only to be computed once, and the whole formula is very easy. In the following table, if the number under xh is multiplied by any half space having the given values of a and c, it gives points in the curve or values of y; and if more points are wanted, the column log. is the logarithm of the denominator in the formula; here the numerator only will require computing.

ig. 2. shews this arch with $a = 2$, $c = 20$, and with spans varying from twenty to seventy feet. These give the result of increase or decrease in that element. Taking now h and c each $= 20$, and making $a = 5$, we see in fig. 3, the effect of increasing the road on the arch, keeping the lower curve height of the road the same, having fifteen feet height, and five feet road; and in the upper curve, where $h = 20$, $a = 5$, and $c = 23$, we see the effect of increasing the road to five feet, and retaining the same height of archway eighteen feet. Fig. 5 is with $h = 9$, $a = 20$, and $c =$ 29. This would be the curve for one of the bridges under the London and Birmingham railway, near the Bull Inn, at the Birmingham end of the line. Fig. 9 shews the effect of lowering the crown; the heights to the road being 10, 15, 20, and 25 respectively, while in each case $h = 20$, and $a = 5$.

hese arches of equilibrium are more adapted for brick than stone, owing to the difficulty of making the arch-stones in the latter radiate properly. In elliptic arches, however, this is not always done: they are made to radiate to one centre, sometimes from ignorance, but oftener because, when properly done, each arch-stone requires a mould for one side; in the curve of equilibrium it will generally be best to assume a centre to the nearest regular figure; otherwise let KD (fig. 1) $= a$, AQ $= t$, DQ $= c$, DP $= x$, and CP $= y$, and $Q^{\frac{1}{2}} = \dfrac{t}{\text{Hy log.}\dfrac{a + c + \sqrt{2ac + c^2}}{a}}$; then the radius of curvature R is $R = \dfrac{\overline{2ax + x^2 + Q)}^{\frac{3}{2}}}{Q^{\frac{1}{2}} + a + x}$; and this is a minimum when $x = \sqrt{\dfrac{Q - a^2}{2}} - a$. The subtangent is equal to $\sqrt{2a + x^2}$. Hy log. $\dfrac{a + x + \sqrt{2ax + x^2}}{a}$.

From any point C in the arch, draw the tangent cb (fig. 1,) then the pressure on the arch-stone at Cg is as the secant of bcp directly and radius inversely. Hence, taking unity as radius, if the depth of the arch-stone at the crown $\left(a\,.\,\overline{\sec.\ bcp})^2\right)$ is multiplied into the sec. bcp, it gives the length of the arch-stone at any point proportioned to its pressure.

The areas being proportional to the weights set off K′, the centre of gravity, draw K′N perpendicular to EN, join K′B, then the pressure in the directions K′N and NB, is as these lines, the former to a lever EN, and the latter to a lever EF. Put the area of the arch $= a$, K′N $= b$, EN $= d$, BN $= f$, FG $= g$, and EF $= x$, then $\dfrac{b}{f}da\cdot$ is the effort to overturn the pier, and xa the resistance; and $\dfrac{bda}{f} - xa$, or $\overline{\dfrac{bd - fx}{f}}\cdot a$ is the difference. The height of the pier is xg, and its resistance on the lever $\frac{1}{2}x$ is $xg \cdot \frac{1}{2}x$, or $\dfrac{x^2g}{2}$; hence for an equilibrium these must be equal, or $\dfrac{bd - fx}{f}, a = \dfrac{x^2g}{2}$, whence $x = \sqrt{\dfrac{2bdag + 4a^2f}{g^2f}} - \dfrac{2a}{g}$.

The centre of gravity may be found near enough, by drawing equidistant lines parallel to KH, (fig. 1,) taking the centre of gravity of each part, and tracing a curve through the points' lines parallel to KQ, which treated similarly, will give another curve, and when this cuts, the first is the centre of gravity. The area may be found by a corresponding process.

VIALES, in *mythology*, a name given among the Romans to the gods who had the care and guard of the roads and highways.

VIANA, a department or corregimento of the province Entre Duro e Minho in Portugal, extending along the seashore to the northward of the river Minho. It comprehends seven towns, 291 villages or parishes, 30,980 dwellings, with about 170,000 inhabitants. The capital is a city of the same name, situated at the mouth of the Minho, a river nearly choked up with sand, and only admitting vessels with a light draught of water to approach the wharfs at the highest tides. From this circumstance the trade of the city has, of late years, been transferred to Oporto. The chief traffic is in fruits and in some light wines. Viana has an extensive sea fishery, which gives occupation to 300 boats. The city is surrounded with walls defended by bastions, and the entrance from the sea is protected by two forts, St. Jago and Cao. The public buildings are two parochial churches, or religious houses, an hospital, a poor house, and a military school or college. It contains about 2000 houses and 9500 inhabitants. There is a light-house at the entrance of the river Lema, whose latitude is in 41° 39′ north.

There is another place in Portugal of this name, the town of Viana in the province of Alentejo, which contains 450 houses and 1850 inhabitants.

In the province of Navarre in Spain, is also a Viana, a city near to Estella. It stands on a hill about three miles from the river Ebro. It is surrounded with walls, and is defended by an ancient castle, and contains 3,500 inhabitants, who are chiefly employed in rearing black cattle, sheep, horses, and mules.

VIBEX is sometimes used by physicians, for a black and blue spot on the skin occasioned by an efflux or extravasation of blood.

VICAR, a person appointed as deputy to another, to perform his functions in his absence, and under his authority.

VICAR, in the canon-law, denotes a priest of a parish, the predial tithes of which are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman who receives them, and only allows the vicar the small tithes, or a convenient salary.

VICENZA, a delegation or province of Austrian Lombardy, within the government of Venice. It is bounded on the north-west by the Tyrol, on the north-east by Belluno, on the east by Treviso, on the south-east by Padua, and on the south-west by Verona. It extends over 836 square miles, is divided into thirteen districts or circles, and these into 113 communes, containing 297,547 inhabitants, who are all of the Italian race, except those who live in seven of the Alpine districts, who are Germans; but all adhere to the Catholic religion. The land is generally level, but some spurs of the western Alps project themselves into the plain on the northern side. It is watered by several streams, which unite near the capital, and there assume the name of Bachiglione. This river is then navigable to the Brenta below Padua, and with it enters the Adriatic sea. The soil is generally good, and for the most part well cultivated, and the face of the country excites the highest gratification to one who travels through it with an agricultural eye. Maize is the chief corn crop. Wheat and rye are likewise cultivated, but are far less productive than maize, which forms almost exclusively the food of the peasantry. Flax and hemp are grown, but not extensively. The chief object of the farmers is the mulberry tree, whose number is rapidly increasing, as well as that of the silk worms that are fed with the leaves. The vines are mixed with the trees, and trained in festoons from one to the other. This has a most charming effect, but is said not to be favourable to the produce of wine, which article is in general of bad quality. A great number of sheep and oxen is fed near the streams or meadows, which are mowed three or four times in the year. The wool is fine, and that, with the cheese, forms a valuable portion of rural wealth.

VICENZA, a city, the capital of the delegation of that name in Italy. It is built on two streams, the Bachiglione, and the Recone, which divides it into two parts connected together by four bridges. It is surrounded with walls, having six gates, one of which, leading to the Field of Mars, is considered the master-piece of the celebrated Palladio. Vicenza contains an ancient castle, twenty-two churches, and thirty-three chapels or oratories, with several hospitals. The inhabitants within the walls amount to 20,478, but including the suburbs, are 33,000. These chiefly find occupation in the various stages of preparing silk. The winding and throwing it, to furnish distant markets, is the chief pursuit, and one which of late has vastly increased, and promises in future a still more rapid increase from the great number of mulberry trees that have been reared. Although some of the streets are narrow, and some few of them crooked, yet no place exhibits such specimens of architectural art as this city and its environs. The most distinguished of the edifices were built by Palladio, who was born here in 1518. The cathedral is a noble Gothic building; but the church of Santa Corona is most admired, especially as it is ornamented with some fine mosaic work and several exquisite paintings. The town-house is the finest specimen of the taste and skill of Palladio, and next to it the *palazzo capitanali*, besides which, the palaces of Triffino, of Volpi, of Dornieri, and the opera-house, are beautiful piles of building. The environs are also distinguished by beautiful villas from the same master, the finest of which is that of Balmarana without the gate. Vicenza, like Verona in the middle ages, became an independent state, and like it, was, in 1405, subdued by the Venetians.

VICRAVANDY, a town in the province of the Carnatic, twenty-two miles west-north-west from Pondicherry. Long. 79. 43. E. Lat. 12. 5. N.

VICTOIRE ISLE, a small island in the eastern seas, covered with wood. Long. 106. 30. E. Lat. 1. 39. N.

VICTOR, SEXTUS AURELIUS, a Latin historian, lived in the age of Constantius and Julian. From the terms in which he speaks of Africa, describing it as "decus terrarum," it has been conjectured that he was a native of that region. According to his own account, he was born in the country, and was the son of a poor and unlettered father. We learn from Ammianus Marcellinus that the emperor Constantius having seen Victor the historian at Sirmium, afterwards appointed him prefect of Pannonia Secunda, and honoured him with a brazen statue. At a subsequent period, as we learn from the same authority, the office of prefect of the city was likewise conferred upon him. He is supposed to have been the same individual who in 369 was consul along with Valentinian.[1] It has been inferred that he was not a Christian.

Aurelius Victor appears to have been the author of a work "De Viris Illustribus Urbis Romæ," which has repeatedly been printed under the names of Cornelius Nepos, Suetonius, and the younger Pliny. The first of his illustrious men is Procas king of the Albani, the last Sextus Pompeius. Of this work, his tract "De Cæsaribus" is to be regarded as a continuation. It commences with Augustus, and terminates with Julian. This tract first appeared in an edition of the author's works published by Andreas Schottus, Antverp. 1579, 8vo. Here we likewise find the earliest impression of the tract entitled "Origo Gentis Romanæ;" but whether it is a genuine production of the same author, has been considered as extremely doubtful. Another work commonly ascribed to him bears the title, "De Vita et Moribus Imperatorum Romanorum; excerpta ex libris Sexti Aurelii Victoris, a Cæsare Augusto usque ad Theodosium Imperatorem." This title is not applicable to a work composed by Victor, but to one compiled from his writings. The materials appear to be borrowed from Suetonius, Eutropius, Ammianus, and Victor.[2]

Of the entire works ascribed to this author there are several editions, accompanied with the notes of various critics. Among these we may specify that of Leyden, Lugd. Bat. 1671, 8vo. An edition "in usum Delphini" was published by Madame Dacier, Paris. 1681, 4to. For another edition we are indebted to Pitiscus, Traj. ad Rhen. 1696, 8vo. But the best edition of Victor is that of Arnzenius, Amst. 1733, 4to.

VICTORIA FORT, a fortified island on the coast of Concun, about seventy miles south from Bombay, which commands a harbour six miles to the north of Severndroog. Long. 72. 55. E. Lat. 17. 56. N.

VICTORY, the overthrow or defeat of an enemy in war or combat.

VICTORY, in Pagan worship, is represented by Hesiod as the daughter of Styx and Pallas; and Varro calls her the daughter of Heaven and Earth. The Romans erected a emple to her, where they prayed the gods to give st cess to their arms. They painted her in the form of a w nan, clad in cloth of gold. In some medals, she is re-p sented with wings flying through the air, holding a lau-re crown in one hand, and a palm in the other; but in ot er medals, she is seen standing upon a globe, with the sa e crown and branch of palm.

---

VIDA, Marco Geronimo, a very elegant Latin poet, w a native of Cremona, but the time of his birth is un-cc ain. Different writers have placed it in 1470, 1480, and 1 0. His parents were noble, but not wealthy. He pro-se ted his studies at Padua and Bologna, and at an early ag was admitted into the congregation of the canons re-g ar of St Mark at Mantua. Here however he did not lc remain, but removed to Rome, where he became a c on of St John of the Lateran. His poetical talents re-co mended him to the favour of Leo the Tenth, who be-st ved upon him the priorship of St Sylvester near Tivoli. V a published a collection of his poems at Rome in the y r 1527. This collection, a quarto of 110 leaves, con-ta s De Arte Poetica libri iii., De Bombyce libri ii., De I lo Scacchorum, Hymni, Bucolica. Leo recommended t im the subject of a sacred poem, which was not com-p ted till after the death of that pontiff. Under the title o "Christiados libri sex," it was published at Cremona i 1535. In 1532 Clement the Seventh had promoted h to the bishopric of Alba. Another pope, Paul the T ird, destined him for the bishopric of Cremona, but died b ore he could fulfil his intentions. Vida composed seve-r other works in verse, and some in prose. When his e scopal city was attacked by the French and the imperi-a ts in 1542, he displayed his courage by urging the gar-r on to make a strenuous defence, and he afterwards con-t uted to the recovery of this conquest out of their hands. I accompanied the papal legates to the council of Trent; a l upon that occasion composed a prose work, entitled ‘ ialogi de Reipublicæ Dignitate," and printed at Cre-na in 1556. He died at Alba on the 27th of Septem-1566, and his remains were interred in the cathedral. la possessed a very elegant taste, and was a great master Latin versification. The art of poetry, the operations of silk worm, and even the game of chess, he has discus-with singular grace and harmony. The encomium of pe rendered his name familiar to English ears:

> Immortal Vida, on whose honoured brow
> The poet's bays and critic's ivy grow.

his poems there are several collective editions. A col-tion, exclusive of his sacred poems, was published by omas Tristram, A.M. Oxon., 1722-3, 2 part. 8vo. But best edition, containing all the poems which he ac-owledged as his, together with the Dialogi, appeared n afterwards, "curantibus J. Ant. et Cajetano Vulpiis. tav. 1731, 2 tom. 4to. Some of Vida's poems have en translated into various languages. Of the Poetics an glish translation was published by Pitt in 1725, and an-er by Hampson in 1793. Of the poem on Chess an glish version is said to have been published by Erskine 1736. A translation of another work, accompanying original, appeared under the title of "The Christiad, a em in six books: translated from the Latin of Marcus eronimus Vida, by J. Cranwell, M.A., Rector of Abbots pton in Huntingdonshire." Cambridge, 1768, 8vo.

VIELLE. (Fr.) a very old stringed instrument, played means of finger-keys, and the friction of a wheel instead a bow. It is much used by wandering Savoyards. In itain it is called a hurdy-gurdy.

VIENNA (Wien), the capital of the circle of Austria, l of the whole Austrian empire, is situated upon an arm the Danube, to the south of the main stream, at the mouth the rivulet Wien, about 500 feet above the level of the , and in north latitude 48° 12′, and east longitude 16° 22′. The city, properly so called, is very small, consisting in 1827, of only 1227 houses, while the suburbs contained 7415. It is surrounded with a strong and compactly built brick wall, rising from fifty to seventy feet above the outer ditch, and forming a fine terrace, which serves as a public promenade, called the Bastey. The Bastey is externally surrounded by the Glacis, an open space, varying in width from about 1200 to 1600 feet, and rising gradually into eminences upon which the thirty-four suburbs are built. These are also surrounded with a wall, the external circumference of which is about fourteen miles, but are completely separated from the city by the Glacis, which has been laid out with fine walks, thus affording, in the very midst of the town, every facility for air and exercise to the inhabitants. Within the narrow circuit of the Bastey, which may be walked round in fifty minutes, is contained almost every object of interest or importance; the Imperial palace, the offices of government, the residences of the higher classes, most of the public museums, libraries, and galleries, the best shops, and, with one exception, all the good hotels. But, like those of most other old towns, the streets of the city are narrow, the places small, and the houses lofty, rising to four or five stories, occupied by different families, and, like those of Edinburgh and Paris, approached by a common stair. Their average number of occupants is about forty; but in the very heart of the city, there are large masses of building, containing more inhabitants than many a large village. They are generally built in the form of a square surrounding a small dark court, and are under the superintendence of a *Hausmeister*, a person appointed by the proprietor to watch over the building and its tenants, to preserve the cleanliness of the common passages, and attend to the street door. It is however fashionable to reside in the city; and even a tradesman domiciliated there holds a higher rank than his brethren in the suburbs. The suburbs are not so splendidly built as the city; but their more elevated situation, their wide and regular streets, and the inferior height of the houses, would seem to render them a preferable residence, were it not for the domineering influence of fashion.

Vienna.

Among the numerous public buildings which adorn Vienna, the following may be enumerated as the principal. The Kaiserburg, or imperial palace, is a very large building, of a most irregular form, consisting indeed of a conglomeration of edifices erected at different times, but presenting, nevertheless, many portions remarkable for their magnificence, and the beauty of their architecture. It stands on the south side of the city, incloses several courts, one of which, Joseph's Platz, is adorned with a fine equestrian statue, in bronze, of the emperor Joseph II. The part used as the residence of the sovereign is called the Schweitzerhof, and is an extensive building forming two sides of a square, but its appearance is not very striking. It however contains large collections of valuable works of art. The rest of the building is devoted to various purposes, comprising, among others, the Hof-Bibliothek, or imperial library, the chancery of the empire, the imperial riding-school, and the theatre of the palace. The library is a temple worthy of the intellectual treasures which it enshrines. It contained, in 1839, 425,631 volumes of printed books in every language, and 17,136 manuscripts, mostly of great value. The palaces and mansions of the nobility are among the most interesting buildings in Vienna, while those devoted to public purposes are seldom worthy of the smallest notice. Among these mansions may be noticed the palace of the Archduke Charles, and the gorgeous palace of the Prince of Liechtenstein. The ancient palace of Prince Eugene, called the Belvedere, was converted into a museum by Joseph II., to whose munificence and taste Vienna is thus indebted for one of the best collections of paintings in Europe, particularly rich in the works of the Flemish and the German schools. The ground floor of the Belvedere also contains a fine collection of ancient armour, and of portraits of the most distinguished persons connected with the house of Hapsburg. The arsenal likewise contains collections of weapons of war ingeniously arranged; and, in the city arsenal, besides sufficient arms for 30,000 men, and a proportional artillery, there is a large collection of Turkish trophies, including the head of the grand vizier, Kara Mustapha, who commanded the Turks at the siege of Vienna in 1683. Vienna is indeed well calculated to afford gratification to the antiquary and the admirer of the fine arts; for, besides the imperial and public collections, many noblemen have their separate galleries and collections, and all are of easy access.

Vienna contains fifty-seven Catholic, one Lutheran, one Calvinist, and four Greek churches, with two Jewish synagogues. The principal of these is the cathedral church of St Stephen, almost in the heart of the city; a beautiful Gothic building, with a steeple remarkable for its symmetry and height. It was begun by the first duke of Austria, before the middle of the twelfth century; in the thirteenth it was twice destroyed by fire, and then rebuilt in its present form. Its greatest length is 355 feet, and its extreme breadth 230; the height of the steeple is 420 or 434 feet, and it is ascended by 753 steps. Next in rank to the cathedral the Viennese reckon the church of St Carlo Borromeo, in the suburb Wieden, erected by the emperor Charles VI., between 1715 and 1737. It is a large massy structure, surmounted by an oval dome cased in glittering copper, and having in front a portico of six Corinthian columns. Before the church are placed two Doric columns, each of thirteen feet diameter, and having their shafts adorned with a spiral band of bas relief; those of the one representing the life and death, and those of the other the actions of the saint. The church of the Capuchins is only remarkable for containing the sepulchral vault of the imperial family, where the remains of its members have been deposited, since the emperor Matthias, in 1619. The coffins are of bronze, oblong in form, and very large. But the hearts of the deceased are deposited in one of the chapels of the Augustinians, and their other viscera in St Stephen's. We may also mention St Peter's church, a poor imitation of St Peter's at Rome; the church of the Augustinians, remarkable for its extent, and for the tomb of the archduchess Christina, the work of Canova; and the church of St Rupert, remarkable for its antiquity, having been originally built in A.D. 740, restored in 1436, and again in 1703.

Vienna is most liberally provided with scientific institutions and charitable establishments. The university, founded in 1237, possesses an astronomical observatory, an anatomical theatre, a laboratory, a good library of 100,000 volumes, a museum of natural history, a botanical garden, and forty-two professors. It was established on its present footing, and the building which it occupies was erected by the empress-queen Maria Theresa, in 1755. Besides the university garden, the late emperor Francis II. established, at the Upper Belvedere, another botanical garden, where may be found almost all the plants indigenous to Germany. There is also a gymnasium, equally well appointed, and a commercial academy, in which pupils are instructed, not only in the usual routine of school learning, but also in the science and the history of commerce, the knowledge of merchandise, and mercantile law, the productions and advantages of all the commercial states in the known world, and those objects of natural history that furnish materials for commerce, manufactures, and philosophy; chemistry as applied to the useful arts; correspondence on all kinds of business; drawing, mechanics, mathematics, &c. For all these branches the pupils pay only three florins (six shillings and twopence) a-month; and for a small additional sum they are taught the Latin, English, French, and Italian languages. The oriental academy is unique of its kind. Here young men are instructed in the oriental languages, and also in the political relations of Austria with the Eastern nations. When their studies are finished, they are employed as secretaries to ambassadors, consuls, or other agents of the government in the East. This excellent institution was founded by the emperor Joseph II., and has produced some of the most distinguished men in the recent history of Austria. The Theresian academy was founded by the empress-queen Maria Theresa, for the education of the sons of the nobility; but her philosophic son, Joseph II., thinking they would be better fitted to perform the duties of good citizens, if educated in a school of more mixed character, suppressed it, and distributed the revenues in pensions to meritorious civil and military officers. His nephew, however, the late emperor Francis II., re-established it on the original plan. It is under the superintendence of a director, and has twenty-one professors, ten masters of modern languages, and several tutors. The medico-chirurgical academy, founded by Joseph II., is one of the finest buildings in Vienna. It has accommodation for 1200 patients; the science is taught by six professors; and the collection of anatomical figures in wax, by Fontanor, is little inferior to that of Florence. The general hospital for the sick, also founded by the same emperor, contains 111 rooms, with 2000 beds, and is computed to receive annually about 10,000 patients. Adjoining to this is the lying-in-hospital, another monument of Joseph's benevolence. There is likewise a foundling hospital, and many other charitable institutions, which reflect the highest honour on the founders, and on the liberality of the government which supports them. Besides the scientific establishments already mentioned, there are also at Vienna an academy of military engineers established in 1717, in which seventy-nine pupils are gratuitously educated; a veterinary school; and the imperial polytechnic school, designed for the instruction of tradesmen in their various arts and professions. The general state of science is however represented as far from flourishing. The number of scientific men is small; and, with the exception of a small medical society, there is no institution, by means of which they can keep up an intercourse with each other. Medicine and the various branches of natural history are the sciences most cultivated. The botanical gardens are good; and the imperial museum of natural history, which occupies several large rooms in the palace, is particularly important. Of all accomplishments, however, a proficiency in music holds the highest place in the estimation of the Viennese; and, in the practice of this art, they are certainly as much above the other nations of Europe (except the Italians), as they are below them in more solid and useful pursuits.

Besides the Bastey and the Glacis, already mentioned, Vienna possesses several other public walks and gardens of great value and importance to the health and recreation of the citizens. The most celebrated of these is the Prater, said to be the finest public park in Europe. It is situate on the north-east of the city, in a large island, formed by two branches of the Danube. From the entrance, the principal drive extends about half a mile in length, divided by rows of trees into five alleys, of which the two outer are appropriated to pedestrians, the next two to equestrians, and the inner one to carriages. Beyond its termination, is the more rural part of the Prater. There the wood becomes thicker, the alleys are no longer straight and formal, but wind irregularly till they are stopped by the banks of the Danube itself. On each side of the drive stretches a verdant lawn, plentifully studded with coffeehouses, and therefore much frequented by the listless pedestrians, who seat themselves under shady awnings, or on the grass beneath clumps of trees, enjoying in idle gaiety their ices, coffee, and cigars. The Prater is frequented daily by the rich and the great, on horseback or in carriages. On Sundays and other festivals the shopkeepers and mechanics likewise resort to it in flocks, to amuse themselves and their children with ninepins, conjurors, see-saws, and roundabouts, and to dine under the trees and the pavilions. Three or four times a-year fireworks are displayed in the Prater, each exhibition of which lasts forty minutes, and represents temples, grottoes, parterres of flowers, fortresses, &c. To the westward of the Prater, communicating with it by two alleys, and on the same island, is the Augarten, a large enclosure, intersected by regular walks, and containing two large eating-rooms, where parties are supplied with dinner, a billiard-room, a dancing-room, and a coffee-room. On the first of May this garden is crowded to excess. The Brigitenau is a large meadow to the west of the Augarten, divided from it by the wall of the suburb, and still on the same island. It contains a church and two public houses, and has its share of company in fine weather. On the first Sunday and Monday after St Bridget's day, a fête is held here; and the number of persons who then come to dance and amuse themselves usually amounts to about thirty thousand. The island which contains these parks and gardens, is connected with the city and the southern suburbs by six bridges. The Volksgarten is a large enclosure, between the Kaiserburg and the south wall of the city; it is in fact the palace garden, but the people are freely admitted, and it forms a favourite promenade. It contains a semicircular building where coffee and other refreshments may be procured; and also a Doric temple, built on the model of that of Theseus at Athens, to contain a group by Canova, of Theseus killing the Minotaur. For in-door amusement, there are several theatres. Two of these are in the city, namely the Burg, or Palace theatre, and the Kaernthnerthor (Carinthian gate) theatre. There are others in the suburbs, and one of them, near the Wien, is capacious and handsome. The imperial theatre, where operas are performed, is not remarkable for its architecture or its stage decorations; but its instrumental and vocal performances may, generally speaking, be called the best in Europe.

The police in Vienna has long been celebrated as one of the most perfect in the world. But its functions are not confined to the ordinary duties of repressing crime, and watching over the public health and convenience; it also takes care that no one presume to discuss too freely affairs of state, or canvass the measures of the government in a spirit opposed to its wishes. Foreigners, and especially those who come from countries where liberal opinions are prevalent, are therefore kept under a vigilant inspection, and any offensive conduct on their part is instantly followed by an order to quit the city. As a necessary appendage to this system, spies are employed, whose official duties are not confined to coffeehouses, and other places of public resort, but extend even to the privacy of domestic life. For the more legitimate, or at least more laudable purposes of police, the city and suburbs are divided into eight districts, to each of which is appointed a physician, a surgeon, an apothecary, and an accoucheur, all paid by government. It is their duty to attend the necessitous sick at their own houses, and to administer advice and medicine gratis. These functionaries are the guardians of the public health, and make a daily report to the police of the births and deaths; and, to guard against secret crimes, the proprietors of houses are obliged to announce to them the deaths of any of their inmates, nor can any person be interred without producing their certificate. In short, their surveillance, in conjunction with that of the police, is extended to the minutest circumstances that can affect the public health. In what may be called compulsory cleanliness, Vienna might serve as a model to every other city. No dirt of any kind is permitted to be thrown into the streets; no accumulated mass of decayed vegetables is ever to be seen in the markets; no slaughter-houses are to be seen throughout the city. Putrefying provisions are never allowed to be sold; no adulterated bread, for that is not only weighed, but chemically analyzed, if suspected to contain improper ingredients; and woe to the offender, for the fine is generally ruinous. The police also regulate the markets and the price of provisions.

Yet notwithstanding all this care, Vienna is decidedly unhealthy, and the climate is generally fatal to delicate constitutions. Colds, catarrhs, and pulmonary complaints are frequent and most malignant. This insalubrity arises from its peculiar situation; for it is exposed to the frequent prevalence of easterly winds, which, blowing over the cold plains of Russia, Poland, and Hungary, the icy tops of the Carpathians, and the waters and marshes of the Danube, increase continually in coldness and dampness till they reach Vienna. To the north wind the city is also equally exposed, while, from the softer influences of the south and the west, it is excluded by a neighbouring chain of mountains, behind which rise the everlasting snows of the Tyrolian and the Carnic Alps. Alternations from heat to cold, and from cold to heat occur two or three times a-day, almost throughout the year. The narrow streets preclude any benefit from the sun, even when he shines; and in dry weather the clouds of dust are intolerable. The mean temperature is from 7° to 9° below zero of Reaumur's thermometer.

Vienna is the most important manufacturing town in the empire, more than 60,000 persons finding employment in different branches of industry. The principal manufactures consist of silk and other stuffs, gold lace, silver lace, ribbons, hardware, and ironmongery goods, needles, philosophical instruments, carriages, and paper. The carriages are prized in most parts of Germany. There are also several porcelain works, one of which employs 150 painters, and about 1500 work people. There are also made steel ornaments, jewels, watches, musical instruments, and chemical productions. There is a cannon-foundry, and a manufactory of arms, belonging to government. Vienna is indeed the centre of Austrian commerce, and of the capital and circulation requisite to maintain it. The produce of its industry gives rise to an exportation sufficient annually to furnish cargoes for 6000 boats, and loads for nearly 2,000,000 of waggons. The canal of Newstadt serves for a communication, not only with that town, but also with the Danube, through the lower part of the Wien. Three annual fairs are held in the town, and the number of mercantile houses amounts to about a thousand. Besides the canal of Newstadt and the Danube, by which Vienna communicates with Hungary and the upper parts of southern Germany, communications have recently been, or are in the course of being, formed with other provinces, by means of railways. The Ferdinand railway, 276 miles in length, commences in the Prater, extends through Moravia and Silesia by Brunn, Olmutz, and Troppau, to the salt mines of Bochnia, beyond Cracow, with various branches; one of which goes to Presburg, and another from Brunn to Prague. Baron Lina's railway extends from Vienna to Newstadt, and onward to Raab, with branches to Modling, Lachenburg, and Baden. It then goes to Oedenburg, and south of the Neusiedler See to Raab. The Mittelbahn, or Central railway, extends from the Ferdinand railway at Gausendorf to Presburgh, Romorn, Pesth, and Debreczin, crossing the Theiss by a very long bridge. The total length of this railway is 326 miles. A line has also been projected to connect Vienna with Trieste; but the difficulty of passing so many large rivers and lofty mountains as intervene, is such as would involve a most enormous outlay, even if the execution of the project were found to be practicable.

The population of the city and suburbs was found, in

Vienna.

1830, to amount to 319,873 souls, without counting the garrison and strangers: including them, the total might be 332,000.

The roads immediately beyond the gates of the suburbs are worse than those around any other capital in Europe; and, for several miles, the country is dreary and devoid of interest. But the more distant environs are highly beautiful, and offer numberless interesting excursions to the citizen and the traveller. On the north are the islands of the Danube; on the west the lofty summit of the Calenberg; on the south the mountains of Styria, covered with forests and vineyards; and on the east, towards Hungary, extensive plains, along which the eye ranges unobstructed to the distant horizon. A few miles east of the capital is the imperial palace of Schoenbrunn (Pretty spring,) which was occupied by Napoleon as his head-quarters in 1805 and 1809. It was built by Maria Theresa, who used it as her favourite residence. The building is large and superbly furnished; the gardens are well laid out and very beautiful; and the situation is delightful. Lachsenburg or Laxenburg is another imperial palace, where the emperor has two residences; the one an ordinary palace, with a theatre and other appendages; the other a sort of model of an ancient baronial castle, with a moat, portcullis, arched gateway, court, hall, chapel, chambers, dungeons, walls, passages, galleries, communications, turrets, and every other proper accompaniment of an ancient fortress. The interior is fitted up in a corresponding style; and at a little distance there is a regular tilting ground, where occasionally mock tournaments have been held for the emperor's amusement. We may also mention Maria Hitzing, near Schoenbrunn, which possesses a theatre and baths, and has been considered the finest and most picturesque village in Austria; Penzing, noted for its ribbon manufactures; Meidling, for its mineral waters; and Baden, fifteen miles south-east of Vienna, a fine town, with 3000 inhabitants, and frequented annually by four or five thousand strangers, to drink its mineral waters; and, near Baden, Weilburg, a magnificent palace recently erected by the archduke Charles.

Notwithstanding all its disadvantages of climate and situation, few places possess such ample resources, such general means of enjoyment, both intellectual and physical, as this imperial city. Its magnificent imperial library, scarcely inferior to any in Europe, and its admirable museums and public galleries, are all open to the public, in a manner so perfect as to arrangement and accommodation, as to render them practically and generally useful. The theatres and the opera are all excellent. The streets are crowded with a lively, active, bustling population. Nothing occurs to annoy or molest the passenger; and in no capital of continental Europe does the stranger, whose passports are regular, and conduct orderly, experience or perceive so little of the interference of the police as at Vienna. No beggars are to be seen; no appearance of poverty meets the eye; no one appears badly dressed. The Viennese are indeed a happy and enjoying people; frugal, cheerful, and contented, they seek no alteration in their condition; they know little of their government but its mild and paternal influence; and they dread changes of any kind as fraught with evil. They see their princes mixing among them with all the simplicity and kindness of private citizens; and they love them with an affection which they believe to be reciprocal. Their general tone of character forms them for tranquil enjoyment in themselves, and promoting it in others; and the lower classes, as well as the higher, are generally found to be mild, kind, and obliging. They are, however, said to be more addicted to sensual than to intellectual pleasures; and the standard of morality is very low among all classes.

Vienna is a place of considerable antiquity, and has been the scene of many historical events. It was originally a small village, encircled by marshes and forests, and peopled by fishermen; but here the Romans established *castra stativa*, or a standing intrenched camp, which gradually became a town, with the name of *Vindobona;* and it was here that the emperor Marcus Aurelius died, A.D. 180. On the decline of the Roman empire, it fell successively into the hands of the Goths and Huns; and in 791 was, with the rest of Austria, attached by Charlemagne to his dominions. The origin of the modern town is commonly ascribed to Henry the First, duke of Austria, who is said to have founded it in or about the year 1142. In 1241 it was taken by the emperor Frederick II., and again, in 1297, by the emperor Rudolph, who bestowed it, with the duchy of Austria upon his son Albert, who became the founder of the archducal, now the imperial family. It was vainly besieged by the Hungarians in 1477; but, eight years afterwards, it was obliged to surrender to Matthias, king of Hungary and Bohemia. It was besieged by the Turks in 1529, and again in 1683; and was relieved, on the latter occasion, only by the arrival of a Polish army, under their king, Sobieski, who beat the Turks with great slaughter before the city. In 1805, it surrendered to the emperor Napoleon; and again in 1809, after a short resistance. Six miles east of the city is the island of Lobau, in the Danube, where the French were encamped for six weeks, in 1809; and opposite it near the north bank of the river, are the villages of Aspern Essling, and Wagram, where were fought the desperat battles which decided the fate of the Austrian monarchy a that time. (C.H.)

ienne.

VIENNE, a department of the south-west division o France, formed out of the ancient province of Upper Poitou It extends in north latitude from 46° 8′, to 49° 9′, and in longitude from 0° 7′ east, to 0° 58′ west. It is bounde on the north by the departments of Mayence and Indre Loire, on the east by the Indre and Loire, on the sout by Upper Vienne and Charente, and on the west by th two Sèvres. The extent is 2640 square miles. It is di vided into five arrondissements, thirty-one cantons, an three hundred communes. It sends two deputies to th legislative chamber, and contained in 1836, 288,002 inha bitants. They all adhere to the Catholic church, excep about 14,000 Calvinists, settled in and around Rouill The people adhere rigidly to their ancient manners an practices, and are reported to be enemies to all improve ment, and to be careless, idle, and ignorant. They ar chiefly agriculturists, and live, as their ancestors lived, in state of great filth and destitution, on the half produce the land; the other half being delivered to the landlord who pay out of it the territorial imposts.

The surface of the department is an elevated plain, un interrupted by any remarkable hills or valleys. In som parts it is sandy, in others clayey, but in all of tolerable f cundity, with the exception of about one-fourth, which uncultivated heath land, but which might be made produ tive if capital could be found, and the ancient prejudices an customs were exchanged for the more modern usages. Mo of these neglected wastes are situated in the eastern divisio of the department, on the arrondissements of Chatelherau and Montmorillon. The principal river, the Vienne, pass through the department, from north to south, about fift six miles, and is the only one that is navigable, and th only for a short distance, and with vessels of a small bu den. It receives in its course the water of numerous sma rivers. The climate is in general mild and temperate, b the north-west winds often bring early and sudden frost which occasionally do great injury both to the corn lar and the vineyards.

The product of corn is insufficient for the consumptio and potatoes, but especially chesnuts, are used as substitut for grain. The quantity of wine produced is considerabl and some of it has the property of being improved by kee ng for many years. Much of it is made into brandy. In ome years, 250,000 hogsheads of wine have been made. he forests have been neglected, and now yield an insuffiient supply of fuel, especially as there is some demand for from the few iron works in the department. The cattle e stated to be only 50,000 oxen, and 175,000 sheep; but ere are numerous swine in proportion to the other anials, amounting to about 45,000. These are mostly sent r the supply of Nantz, Rochelle, and Rochefort. Sufcient hemp and flax are grown to provide employment in inning, and linen cloth for common use. The only manuctures besides iron already noticed, are some paper, rthenware, leather, and coarse woollen goods, but barely fficient for the internal demand. From the water comunication being slight, and the roads in bad condition, ere is little commerce, and that consists of the export of ules, swine, walnuts, chesnuts, wine, brandy, and, in ars of extraordinary productiveness, a little corn.

VIENNE, UPPER, a department in the north-west of rance, formed out of the Upper Limousin, and the disicts of La Marche and Poitou. It is situated in north laude between 45° 26′, and 46° 24′, and in east longitude etween 0° 33′, and 1° 41′. It is bounded on the north the departments of Vienne and of Indre, on the east by at of the Creuse, on the south by the Correze and the ordogne, and on the west by the Charente. It is 2165 uare miles in extent, is divided into four arrondissements, d those into twenty-seven cantons, containing 198 comunes or parishes. It contained in 1836 a population of 3,011, all of whom adhere to the Catholic church. They e represented as indolent and uninstructed, but kind and aritable, as penurious, and yet hospitable. The institions for instruction are few and very ill conducted. The ce of the country consists of mountains, hills, deep chasms, d narrow valleys, but presents no extensive plain. The ountains are of granite. The highest of them are in the uth part of the frontiers of the department of the Creuse d the Correze, and decline gradually in height towards e departments of the Charente and the Vienne. The eatest height of any of them does not exceed 3000 feet. he rivers, which amount to thirty-eight in number, are pid, and in their course have worn themselves deep beds the granite or schistose hills. The principal are the ienne, 240 feet wide at Limoges, the Gartempe, the rdoer, the Venaise, the Graire, and the Issoire, none of hich are navigable. There are some lakes, but none of eat extent. The climate is damp, cold, and highly vable. The frost begins early, and ends late. The meum heat of the year at Limoges is from eight to nine of eaumur greater than in Paris, though it is three degrees uth of that city. The appropriation of the soil is, accorng to the "Statistique de la France," 554,266 hectares, hich is divided nearly in the following order:—Ploughed d, 248,599 hectares; water meadows, 93,960; upland sture, 47,516; 9870 commons, 2969 vineyards, 33,563 esnut wood, 39,580 forests, 4300 gardens, 14,480 sites houses and roads, 2969 courses of rivers, dikes, and lakes, d 64,173 uncultivated heaths. Little alteration has ken place in agriculture during the last two hundred ars, except by the introduction of potatoes. As the naes speak a patois something like the Provençal, they have s means of becoming acquainted with the improveents made in the other parts of France; and almost the hole is cultivated on the *Metayer* system. Frequent falws are necessary, and with them very little wheat is sed; about the same quantity of buck wheat, and about ght times as much rye. The oats, barley, and maize do t together yield half as much grain as the wheat alone. he most beneficial husbandry is the breeding of cattle: ese are sold for the markets in the large cities near it, d some even in Paris. The annual sale to other departments is about 10,000, and 15,000 oxen and cows. In the department, there are about 600,000 sheep of small size, and with coarse wool, but they are much annoyed by the wolves. One important product is the chesnut, of which more than a million quintals are annually harvested. They are used as a substitute for bread by the inhabitants, but some are sent to other districts. The forests have been much neglected, and now yield little timber for building, and but a scanty supply for fuel.

There are mines of antimony, tin, and iron, but the product of them is inconsiderable. There are some valuable clays adapted for making porcelain. The manufactures are mostly of the domestic kind, such as that of spinning flax, and weaving it into linen. Some woollen and cotton goods are made in the city of Limoges, the capital of the department.

VIENNE, an arrondissement of the department of the Isère, in the south-east of France. It is 690 square miles in extent, is divided into ten cantons, distributed in 132 communes, and contained 145,001 inhabitants in 1836. The chief city, bearing the same name, is built on the side of a hill on the left bank of the river Rhone, from which it rises like an amphitheatre. It consists of narrow and crooked streets, but has a fine promenade recently formed on the side of the stream. It has a cathedral of great beauty, several other churches, a museum, a theatre, and some extensive barracks. In 1836, it had a population of 16,484 persons, chiefly occupied in making paper, linen goods, iron and copper ware. It is one of the most ancient cities of France, and the capital of the ancient Gauls; and various reliques of antiquity are from time to time discovered.

VIERLANDS, four small islands in the river Elbe, a little above the city of Hamburg, and under the joint government of that city and of Lübec. The inhabitants are a colony of Dutch who came to these spots on a religious account, and who still retain their ancient language, religion, dress, and manners. They are, in fact, the market gardeners of the city of Hamburg, and supply its inhabitants with the best of culinary vegetables and fruits. The names of the islands are, Old Gamme, New Gamme, Kirkwarden, and Kosslacke. They form four parishes, and contain a population of more than 7000 persons.

VIERZON, a city of France, in the department of the Cher, and the arrondissement of Bourges. It stands at the point where the rivers Eure and Eber unite, and contained in 1836, 4706 inhabitants, employed in making hosiery, woollen goods, and leather. Lat. 47. 12. Long. 1. 58. E.

VIGER, **FRANCOIS**, more generally known by the name of Franciscus Vigerus, a learned Jesuit, was a native of Rouen, and died there in the year 1647. His treatise entitled "De præcipuis Græcæ Dictionis Idiotismis liber," is said to have been originally published in 1632. The subsequent editions are very numerous, and some of them are enriched by the emendations and additions of Hoogeveen, Zeunius, and Hermann. An edition, including the annotations of all the three, has been printed in our own country. Glasg. 1823, 8vo. In this improved form, the work possesses great value. Viger published an edition of Eusebius, "De Preparatione Evangelica," accompanied with notes and a new Latin version. Paris. 1628, fol.

VIGEVANO, a province of the kingdom of Sardinia in Italy, in the principality of Piedmont, on the frontier towards Milan. It is a level and rich, though small district, producing wine, silk, and some rice. The capital is of the same name, is the seat of a bishop, and is situated about two miles from the river Tessin. It is surrounded with walls, has an old castle, and contains besides a beautiful cathedral, two parish churches, seven monasteries, and three nunneries, to each of which there is attached a church. The inhabitants are 15,200, very industriously occupied in raising silk, and in making silk goods, especially stockings and handkerchiefs. Lat. 45. 18. 54. Long. 8. 46. 56. E.

VIGIL, in church history, is the eve or next day before any solemn feast; because then Christians were wont to watch, fast, and pray, in their churches.

VIGILS *of Plants*, a term under which botanists comprehend the precise time of the day in which the flowers of different plants open, expand, and shut.

VIGILANTIUS, the bold opponent of ecclesiastical corruptions in the fourth century, and the forerunner of those who have since testified for scriptural truth, and protested against certain errors of the ancient fathers. Others of the same, or of an earlier period, may have offered some occasional opposition to superstitious practices, as they crept into the church; but Vigilantius openly denounced relic and saint worshippers as *cinerarios et idololatras*.[1] He made an uncompromising attack upon the obligation to celibacy, the adoration of saints, prayers for the dead, the use of relics, and pilgrimages, and exposed their mischievous tendency, at the critical time when they were sanctioned by such eminent men as Ambrose, Chrysostom, Jerom, and Augustin. He was one of those resolute inquirers, who dare to think for themselves, and who appear at intervals, after the lapse of centuries, to remind Christians that they are to abide by the rule of thought and action, which is laid down in the book of God's revealed will, and are not to be satisfied with any canon which cannot be examined by that standard. He may therefore have a place given to him in that noble phalanx, in which Claude of Turin, Valdo of Lyons, Luther, and Calvin, took their stand, for the defence of the pure gospel.

Vigilantius was born about the year 360, at the foot of the Pyrenees, under the warm sun which fertilizes Aquitaine, and in the midst of that majestic scenery which calls forth latent genius, and gives a tone of independent character to the native of the mountains. Calagorris,[2] now called Caseres, was his birth-place; not Calagorris in Spain, but a village on the northern side of the Pyrenees, so named by a band of insurgents, who were driven by Pompey from the Spanish borders, and settled on the Gallic frontier.[3] The father of Vigilantius kept the *Mansio*,[4] or station at Calagorris, where travellers were supplied with post-horses and guides to conduct them through the passes; and this brought the young mountaineer under the notice of Sulpicius Severus, the historian, who took him into his service, and employed him in the management of his estate, and in the sale of the wines which it produced.[5] For his good conduct in this situation, he was taken into the confidence of his patron, and lived with him more in the character of a friend than a dependent. There are some beautiful letters still extant, which passed between Sulpicius Severus and Paulinus of Nola, in which Vigilantius is mentioned in the warmest terms of affection;[6] and no doubt he was indebted to his familiar acquaintance with these two eminent persons for his first serious impressions. Had he not been a man of uncommon strength of mind, he would have fallen into the same errors which clouded their religious views Happily and providentially, however, he was enabled t turn their example to advantage, even on points in which they were misguided, by avoiding the rocks on which they split; and he became a reformer where he might have been a sceptic, or at least a scorner, with such extravagancies before his eyes as they practised under the name of religion. Sulpicius, in a season of great mental distress, wen to Martin, bishop of Tours,[7] for instruction and consolation and it is probable that Vigilantius accompanied him on one or two of his visits to that gloomy ascetic, in 392 or 393 and witnessed some of those acts of austerity[8] and pretensions to miraculous power,[9] which proved Martin to be an impostor or a crazy fanatic, and opened the eyes of the young man to the true character of a system, which turned the head of his master, and made him the victim of a spiritual delusion.

Sulpicius devoted the whole of his immense property to the exercise of almsgiving and hospitality. His beautifu villas at Primuliac and Elusone, near Tholouse, were made the asylums of the mendicant and the wayfaring man. He built churches; he founded a monastery; he entertained strangers; he treated his domestics as if they were his nea relations; and he lived in the practice of every Christian virtue.[10] He watched, he prayed, he fasted. But this wa not enough. Wrought up to the highest pitch of religiou fever by Martin, and others of a disordered imagination, he believed that his oblations of faith and piety would be unacceptable to heaven, unless they were accompanied by the most rigid self-denial and self-infliction. But the more he tormented himself, the more did fears, utterly inconsisten with the covenant of reconciliation and the pardon of sins offered in the gospel, prey upon his heart and understanding. Vigilantius observed the melancholy and maddening effects produced in the noble mind of his protector, and learnt to abominate the lessons which degraded "the Christian Sallust," as Sulpicius was called, to the level of a credulous and extravagant narrator of false miracles.[11]

He likewise had opportunities of seeing how leaven o the same kind worked in Paulinus of Nola, and how spoilt his Christianity. That illustrious and amiable sain (for saint he was, in spite of his religious mistakes), wa persuaded by the advocates[12] of an ascetic rule of life, whic was falsely called Christian perfection, to renounce the comfort and privileges of wedlock, to live with his wife as with a sister, to desert his post of duty, to deny himse the necessaries of life, to abandon the world, to practis severities on his person, and to have recourse to superst tious observances, which reduced his body to a skeleton and his mind to a state bordering on imbecility.

Vigilantius continued to pass his time in the society o Sulpicius, in Aquitaine, or of Paulinus, in Campania, unt the year 394 or 395, and with them he had the best opportunities of cultivating sacred learning, and of discussing theological questions. But succeeding to considerable propert on the death of his father, about that time, he resolved to tak a ourney to the East for his mental improvement, and car- r d a letter of introduction from Paulinus to Jerom,[1] who v s then dwelling as a recluse in Palestine. This intro- c tion, which took place after he was in priest's orders, v s a turning point in his life. The errors for which he n ght have had some respect, in connection with such g ntle and humble servants of God as Sulpicius and Pau- l us, (and never is error so dangerous as when recom- n nded by good and holy men), became disgusting in the s r and choleric monk of Bethlehem, whose learning gave a ting to his acerbity. It was unendurable to be a spec- t or of Jerom's spiritual pride, and to hear him revile e ry body whose opinions were opposed to his own, while l professed to make the birth-place of the meek and lowly J us his abode, in order that he might be the better able t keep his body in subjection. Their disputes ran high, a l Jerom, who began by speaking of Vigilantius as "the l y presbyter,"[2] and "Christian brother,"[3] soon changed l opinion, and heaped every epithet upon him that was n st expressive of contempt and resentment. He punned u on his name, and called him *Dormitantius*, and inveighed a inst him as an ignorant pretender to learning.[4] "Tap- s r," "madman," "monster," "possessed of a devil," " eretic,"[5] "Samaritan," "worse than a Jew;" these were s ne of Jerom's terms of reproach applied to Vigilan- t s; but we search in vain for any fair grounds of accusa- t n in justification of such language, which has been con- (nned by some of the best writers of the Romish church. charges of heterodoxy on the great doctrines of atone- r nt and justification, no imputation of doubtful faith on t doctrine of the Holy Trinity, are advanced against l n. The sum and substance of Jerom's indictment a ounts to this, that Vigilantius denied the sanctity of r ics; that he refused to worship and to burn lights at the t nbs of the martyrs, and to invocate saints; that he dis- a proved of vows of celibacy, of pilgrimages, and of noc- t nal watchings in cemeteries;[6] that he doubted the pre- s ice of departed spirits at the places where their bodies re buried; that he questioned the tales of miracles said t have been wrought at the sepulchres of the martyrs; a l that he protested against the imputed efficacy of yers, either *for* or *to* the dead.[7] Unfortunately we have thing left but Jerom's account of the controversy; and gilantius only speaks for himself in the pages of his adver- y, in some of which he is represented precisely in the same ht, and almost in the same words, as the early Christians re by their pagan calumniators. Jerom hated Vigilan- s personally, because he had accused him of inclining to ne of the opinions of Origen. Fleury admits that Je- n was too vehement in his controversy with Vigilan- s; and Erasmus makes use of a stronger expression, lebacchatur convitiis."[8] After making some stay in Pa- tine and Egypt, Vigilantius returned to Gaul in 396;[9] l on his way he visited a Christian community in the ttian Alps, the ancestors, as we have reason to believe, the Valdenses, among whom he found persons entertain- the same opinions as his own. This visit may have n occasioned by a statement of Ambrose relating to the nions and practice of his mountain clergy. Claude, hop of Turin, four hundred years afterwards, was said to ive the sect of Vigilantius[10] in those parts; in other words, to attempt to put down the same abuses which Vigilantius had exposed.

[12] By Jerom, among others, who told him he must make an absolute renunciation of all he had, and voluntarily embrace enti poverty, if he wished to be perfect. It is in vain to defend the Christianity of the fourth century from the charge of fanaticism See Epist. Hieron. ad Paul. 49. Opera iv. par. ii. p. 563.

During the eight years that followed, he officiated as priest in the diocese of Tholouse, not far from the Pyrenees; but he does not seem to have been confined to the duties of his parish;[11] for we read of his making excursions into different parts of Gaul to collect books, to copy MSS., and to put himself into communication with bishops and clergy whose sentiments were similar to his own. Jerom's invectives against those Gallic prelates[12] who advocated the same cause as Vigilantius, and his reproof of Exuperius, bishop of Tholouse, for not silencing him "with a rod of iron,"[13] prove that there was a strong attempt, at this time, to correct those superstitious practices of the church of the fourth century, which Vigilantius denounced as having an idolatrous tendency. It is quite clear, that the Aquitainian clergy leant, for the most part, towards the opinions of Vigilantius, because nobody was found in southern Gaul to contradict him; and for that reason Jerom undertook to rebuke and refute him, at the request of Riparius and Desiderius. The influence of the Pyrenean presbyter was exercised in another way; he employed much of his time and his fortune in the transcription and circulation of copies of Scripture.[14]

The zeal of Vigilantius in his endeavour to check the progress of corrupt innovation, was unremitting till the time of his death, which took place, it is supposed, during that terrible invasion of the barbarians, the Alans and Vandals, which desolated the south of Europe at the beginning of the fifth century. In 401 and 403, and again in 406, we find Jerome writing against him,[15] and describing his persevering efforts in the dissemination of his principles; but after that no more mention is made of him. The full benefit of his protests against antichristian novelties was not felt, either in his lifetime or in the ages that immediately followed. But he was one of those champions of the faith raised up in fulfilment of the promise, that the gospel of truth shall never be without a witness; and it was reserved for a happier era to establish the doctrines which he so faithfully maintained. (D. F.)

VIGO, a sea-port of Spain, in the province of Galicia, more remarkable for the excellence of the bay on which it stands. Vigo bay is entirely enclosed with high mountainous land, broken by cultivated valleys, which form a pleasing landscape. It is entered by a long channel, in which there are from twenty-seven to thirty-two feet of water. The beach is clear, the holding ground good, and there a ship is well sheltered from the sea by the Bayona islands. The town is surrounded by an ancient wall, and is defended by a citadel. The harbour, though so well situated, is little frequented by any but coasting vessels. Vigo contains not more than 2500 inhabitants. It is remarkable as the place where a Spanish plate-fleet took refuge in the year 1702, and was attacked by a combined fleet of the British and Dutch ships, then at war with Spain. The victory was complete, but the Spaniards set fire to the richest of the treasure-ships, which were burnt and sunk. It was to this place that General Crawford led the light division of Sir John Moore's army, on its retreat from Spain, and embarked it with despatch and without loss. The latitude is 42. 13. 20. N. Long. 8. 33. 30. W.

VIJANAGRAM, a considerable town of Hindustan, in the Northern Arcons, twenty-five miles north by west from Vizapatam. Long. 83. 30. E. Lat. 18. 4. N.

VILLAFRANCA, a small town in the delegation of Verona in Venetian Lombardy, with a population of 2000. It is nine miles distant from Verona.

VILLAFRANCA, a town of Spain, in the province of Estremadura, distant from Madrid about 200 miles. It is a place of but little importance, and has a population of about 2500.

VILLACH, a circle in the Austrian government of Laibach in Illyria. It is bounded on the north by the Upper Ens, on the east by Klaganfort, on the south by Laibach and Venice, and on the west by Tyrol. It extends over 2200 square miles, and comprehends four cities, eleven market towns, and 1147 villages, with 112,980 inhabitants. It is mostly an alpine district, with lofty mountains covered with snow, but intermixed with valleys of great beauty and fertility, and several picturesque lakes and waterfalls. The chief occupation is mining, by which some little silver and less gold is obtained, but more considerable quantities of lead, copper, antimony, and quicksilver. There are also many valuable quarries, yielding marbles of great beauty. The capital is the city of the same name, on the river Drove. It is well built and strongly fortified, contains two churches, 360 dwelling-houses, and 4820 inhabitants, who are chiefly employed in converting the minerals into common utensils. Lat. 46. 35. Long. 13. 42. E.

VILLAGE, an assemblage of houses inhabited chiefly by peasants and farmers, and having no market; a circumstance by which it is distinguished from a town. The word is French, formed from the Latin *villa*, a country house.

VILLEFRANCHE, one of the arrondissements of the department of the Rhone, in the south of France, containing 584½ square miles, and divided into 9 cantons, 127 communes, with 151,980 inhabitants in 1836. The capital is the city of the same name, situated on the river Morgon, near to the left bank of the Paone, in a most fertile district. In 1836 it contained 7553 inhabitants, who make cotton and woollen goods, and carry on a considerable trade in wine, corn, cattle, and other agricultural productions. Long. 4. 38. E. Lat. 48. 59. N.

VILLEFRANCHE, an arrondissement of the department of Aveyron in France, extending over 493½ square miles. It is divided into four cantons and forty-eight communes, having 81,130 inhabitants in 1836. The capital is the city of the same name, situated at the junction of the rivers Alson and Aveyron. It is well built, and in 1836 contained 8738 industrious inhabitants, occupied in making linen goods, paper, hats, copper ware, and other articles. Long. 2. 3. E. Lat. 41. 24. N.

VILLENA, a city of Spain in the province of Murcia. It is situated on the north-east of the river Jumilla, in a bleak and mountainous country. Near it is a salt lake, two leagues in circumference, which supplies the neighbouring district with salt for culinary purposes. The whole of the surrounding country is studded with the remains of fortresses built by the Moors. From this elevated country, the capital and other places on the coast draw their supplies of ice. The city contains fourteen streets, and 8000 inhabitants. It is situated in Lat. 38. 36. N.

VILLEIN, or VILLAIN, in our ancient customs, denotes a man of servile or base condition, viz. a bondman or servant.

VILLENAGE, in *Law*. The folk-land, or estates held in villenage, was a species of tenure neither strictly feudal, Norman, nor Saxon, but mixed and compounded of them all; and which also, on account of the heriots that usually attend it, may seem to have somewhat Danish in its composition. Under the Saxon government, there were, as Sir William Temple speaks, a sort of people in a condition of downright servitude, used and employed in the most servile works, and belonging, both they, their children, a effects, to the lord of the soil, like the rest of the cattle stock upon it. These seem to have been those who he what was called the *folk-land*, from which they were moveable at the lord's pleasure. On the arrival of t Normans, it seems not improbable that they who we strangers to any other than a feudal state, might give so measure of enfranchisement to such wretched persons fell to their share, by admitting them, as well as others, the oath of fealty, which conferred a right of protecti and raised the tenant to a kind of state superior to dow right slavery, but inferior to every other condition. T they called *villenage*, and the tenants *villeins*.

These villeins, belonging principally to lords of manc were either villeins *regardant*, that is, annexed to the n nor or land; or else they were *in gross*, or at large, that annexed to the person of the lord, and transferable by de from one owner to another. They could not leave th lord without his permission; but if they ran away, or w purloined from him, might be claimed and recovered action, like beasts or other chattels. They held inde small portions of land by way of sustaining themselves a families, but it was at the mere will of the lord, who mi dispossess them whenever he pleased; and it was u villein services, that is, to carry out dung, to hedge a ditch the lord's demesnes, and any other the meanest fices; and their services were not only base, but uncert both as to their time and quantity. A villein could quire no property either in lands or goods; if he purch ed either, the lord might seize them to his own use, less he contrived to dispose of them again before the l had seized them, for the lord had then lost his opportun

In many places a fine was also payable to the lord the villein presumed to marry his daughter to any without leave from the lord; and by the common law, lord might also bring an action against the husband for mages in thus purloining his property; for the childre villeins were also in the same state of bondage with th parents; whence they were called in Latin *nativi*, wh gave rise to the female appellation of a villein, who called a *neife*. In case of a marriage between a freem and a neife, or a villein and a free woman, the issue follo ed the condition of the father, being free if he was fr and a villein if he was villein, contrary to the maxim the civil law, *partus sequitur ventrem*. But no bast could be born a villein, because by another maxim of law, he is *nullius filius;* and as he can *gain* nothing inheritance, it were hard that he should *lose* his natu freedom by it. The law however protected the persons villeins against atrocious injuries of the lord; for he mi not kill or maim his villein, although he might beat h with impunity.

Villeins might be enfranchised by manumission. process of time they gained considerable ground on th lords; and in particular they strengthened the tenure their estates to that degree, that they came to have in th an interest in many places fully as good, in others bet than their lords. For the good-nature and benevolenc many lords of manors having, time out of mind, permit their villeins and their children to enjoy their possessi without interruption, in a regular course of descent, common law, of which custom is the life, now gave th title to prescribe against their lords; and, on performa of the same services, to hold their lands in spite of any termination of the lord's will. For though in general t are still said to hold their estates at the will of the lo yet it is such a will as is agreeable to the custom of manor; which customs are preserved and evidenced by rolls of the several courts-baron in which they are enter or kept on foot by the constant immemorial usage of several manors in which the lands lie. And as such t ants had nothing to show for their estates but those c oms, and admissions in pursuance of them, entered on hese rolls, or the copies of such entries witnessed by the eward, they now began to be called *tenants by copy of urt roll*, and their tenure itself a *copyhold*.

VILLENEUVE D' AGEN, an arrondissement of the epartment of the Lot and the Garonne, in France, ex- nds over 560 square miles, and is divided into six can- ns, with eighty-six communes, which contained in 1836 ,961 inhabitants. The capital is a city of the same name the river Lot, with a population of 11,222 in 1836.

VILLIERS, GEORGE, duke of Buckingham, was the ird son of Sir George Villiers. He was born at Brookes- y in Leicestershire, August 20, 1582. His handsome erson and pleasing manners gained him the favour of ames I., who, in 1615, created him a knight, with a ension of L.1000 a-year. From this time, his promotion as rapid, and his influence with King James unbounded; ter whose death, he continued as great a favourite with s son. But for his transactions, which are matter of his- ry, we refer to the article BRITAIN. He was assassinated Portsmouth by one Fenton, August 23, 1628.

VILLIERS, GEORGE, second duke of Buckingham of that mily, son of the preceding, was born at Westminster, Ja- ary 30, 1627. During the civil wars, he served in the royal my under Prince Rupert. After the death of Charles I., attached himself to his son, and at the restoration was ade master of the horse, and was one of those confidential inisters of the king who were designated the Cabal. His iblic conduct was unprincipled and capricious, and his pri- te life notorious for profligacy and crime. He died April , 1688, justly neglected and despised. See BRITAIN.

VIMIERO, a small town of the province of Alentejo, the kingdom of Portugal. It stands on a mountain, and ntains 430 houses, with about 1800 inhabitants, and is ly remarkable as the scene of one of that series of vic- ries gained by the duke of Wellington during the penin- lar war.

VINA or BIN, a singular musical instrument of India, of e lute kind. Mersenne describes and gives a repre- ntation of it in the twenty-first proposition of the second ok of his Harmonics. It is minutely described in the siatic Researches.

VINCATGHERRY, a town of Hindostan, in the Mysore jah's territories. It is built on a rising ground, and con- sts of several inclosures surrounded by walls of stone, and nked with towers and bastions, which rise higher and gher towards the central inclosure, in which stood the jah's dwelling. It is distant 120 miles west from Madras. ong. 78. 38. E. Lat. 13. 2. N.

VINCENT, ST, one of the windward West India islands, situate in 13° N. Lat. and 61° W. Long. It is seven- en miles long from north to south, and ten miles broad. eing discovered by Columbus on the 22d January (1498), hich is St Vincent's day in the Spanish calendar, he named after that saint. It was then inhabited by a warlike race of aribs. The first settlement of Europeans was made by body of adventurers from Martinique in 1719. It was ng a neutral island, but, in 1762, it was taken possession by the English, and ceded to them by the treaty of Paris the following year. At the instance of some rapacious anters, the English engaged in an unjust war against the arribees who inhabited the windward side of the island, d who were forced to consent to a peace, and to cede a rge tract of valuable land to the crown. The consequence this was, that in 1779 they greatly contributed to the duction of the island when attacked by the French. It as however restored to England at the peace of 1783, d has, since that time, continued in the possession of ritain. The population amounted in 1831, to 27,122, of hich 1,301 were whites. The number of registered slaves the 1st of August 1834, was 22,266; and the amount of mpensation paid out of the parliamentary grant was, L.590,779, or L.26, 10s. 7d. each. The amount of exports in 1836 was, 21,694,512 lbs. of sugar, 242,637 gallons of rum, and 394,830 gallons of molasses. The total value of the exports was, L.349,480, and the imports for the same year, L.155,522. The island has a local legislature, consisting of the lieutenant-governor, a council of twelve members appointed by the crown, and an assembly of nineteen members elected by freeholders of ten acres of land, or of a house of the yearly value of L.20 in the town, or of L.100 in the country.

Vincent, St.

VINCENT, GULF OF ST, a large inlet in the south coast of New Holland, extending eastward about forty-five miles, and sixty miles farther in a northern direction. At its mouth it is not more than nine miles broad, but afterwards widens to more than double the breadth.

VINCENT, JOHN JERVIS, EARL OF ST, a distinguished naval officer, was born at Meaford, in Staffordshire, on the 9th of January 1734, old style. His father, Lwynfen Jervis, Esq., was counsel and solicitor to the admiralty, and treasurer of Greenwich Hospital. Young Jervis was destined for the law, but having contracted a dislike to that profession, and a strong predilection for the sea, he ran away from school, and expressed his determination to be a sailor. He was therefore placed under Commodore Townsend, who was at that time going out in the Gloucester as commander-in-chief to Jamaica. This was in the year 1748. In 1754 he was made a lieutenant out of the Prince into the Royal Anne; and in the year 1759 he distinguished himself very much at the siege and capture of Quebec, when General Wolfe was killed. He was in consequence promoted by Sir Charles Saunders, the commander-in-chief, to the rank of commander into the Porcupine sloop of war. In the following year he was made a post-captain. He commanded the Foudroyant in July 1788, when the memorable rencontre took place between Admiral Keppel and Count d'Orvilliers, and bore a very distinguished part in that action. In 1782, Captain Jervis fell in off Brest harbour with the French ship Pegase, of seventy-four guns and 700 men, and took her after an engagement which lasted three-quarters of an hour. The Pegase had eighty men killed and wounded, while Captain Jervis and four men only were wounded on board the Foudroyant. In consequence of this action, which at once raised his renown to the highest pitch, he was created a knight companion of the Bath. In 1784 he was elected member of parliament for Launceston, and he afterwards sat for North Yarmouth. In 1787 he was advanced to the rank of rear-admiral of the blue, in 1793 to that of vice-admiral, and in 1795 he became admiral.

In November 1793 an expedition was fitted out to attack the French Carribee islands, and Sir Charles Grey and Sir John Jervis were nominated respectively to command the land and sea forces to be employed on the occasion. The expedition was at first completely successful, and Martinique, St Lucia, and Guadaloupe, were surrendered to the British arms. The French however succeeded in retaking Guadaloupe, and the rainy season and the yellow fever frustrated all the efforts of the British to regain possession of it. In 1795, on the resignation of Admiral Hood, Jervis was appointed to the command of the British fleet in the Mediterranean, and was employed in blockading the French fleet in Toulon, and protecting our trade in the Levant, a service which he performed with consummate skill and success.

In 1797 Admiral Jervis, with only fifteen ships of the line, gained his celebrated victory over the Spanish fleet, consisting of twenty-seven ships of the line. The engagement, which took place off Cape St Vincent, on the 14th of February, lasted about ten hours. The Spaniards were completely defeated, and four sail of the line, two of 112, one of 84, and one of 74 guns, were taken. The thanks of both houses of Parliament were voted to the fleet, and

Vincent, St.

the commander-in-chief was created a peer, by the title of Earl of St Vincent. This victory was much more important in its consequences than might be supposed from the mere numerical loss which it caused to the enemy. It paralyzed the power of Spain, gave encouragement to our allies, and added fresh vigour to the efforts of the government in prosecuting the war. The battle of Cape St Vincent was followed by the mutiny of the British fleet at Spithead; and in the month of May and June following its effects were felt in the fleet which was cruizing before Cadiz under the command of Lord St Vincent. But the ringleaders were executed, and the mutiny speedily repressed by the resolute and determined conduct of the commander-in-chief, with a combination of humanity and ingenuity eminently characteristic of the man: he contrived to make one execution produce the effect of many, by ordering it on an unusual day, Sunday morning. It was the practice to dispatch mutinous vessels to serve under his orders; and by his masterly operations of combined mercy and justice, he soon reduced them to order, restoring discipline by such examples as should be most striking, without being more numerous than absolute necessity required. In June 1799 he resigned the command of the fleet, in consequence of ill health, and returned to England in the month of August following. On the resignation of Lord Bridport, and his final retirement from active service, he was appointed to the command of the Channel fleet, and in the spring of 1800 hoisted his flag in the Ville de Paris. In the following year, on the formation of the Addington ministry, he was made first lord of the admiralty, and in that important office the great capacity for business with which he was endowed by nature shone forth in all its lustre. He instituted the celebrated Commission of Naval Inquiry, which not only led to numberless discoveries of abuse and extravagance, but laid the foundation of a system of economical administration, which has since been extended from the navy to all the departments of the state. The extent of corruption brought to light by the Commissioners of Naval Inquiry almost exceeds belief. From the dockyard only the government was plundered at the rate of a million sterling annually, and the same nefarious practices prevailed in all the other departments. Lord St Vincent grappled boldly with these monstrous and deep-rooted abuses, and by his unsparing rigour, inflexible honesty, and resistless energy, succeeded in putting them down. "It is impossible," says Lord Brougham, "to calculate what would have been the saving effected to the revenues of this country, had Lord St Vincent presided over any great department of national affairs from the beginning of the war, instead of coming to our assistance after its close." The resignation of Mr Addington in 1804 put an end to the naval administration of St Vincent, as first lord of the admiralty; but the exigencies of the state caused him in 1806 to be called from his well-earned retirement, and from the enjoyment of his domestic comforts, at the age of seventy-two, to take the command of the Channel fleet. He was at the head of the expedition, and the commission sent to the court of Portugal in 1806; and his conduct in that delicate and important affair displayed great talents and address. In the spring of 1807, advanced age and impaired health compelled him finally to resign his command. The remainder of his life was spent in retirement at his beautiful seat of Rochetts, where he died on the 14th of March 1823, in the eighty-eighth year of his age. The character of Lord St Vincent presented an admirable union of the brightest qualities which can adorn both civil and military life. As a statesman, he was distinguished for his sagacity and foresight, and the profoundness of his views. He was a steady and consistent supporter of liberal principles, ever preferring the side of humanity and freedom. He was not more distinguished for his great talents than for his magnanimity and complete freedom from eve feeling of jealousy or envy. And it has been justly said t one who knew him well, that "all good officers, all me employed under him, whether in civil or military servic spoke of him as they felt, with admiration of his genius a proaching to enthusiasm." (Captain Brenton's Life Earl St Vincent. Lord Brougham's Statesmen of t Times of George III.)

B. Q.

VINCI, Leonardo da, an illustrious Italian painte descended from a noble Tuscan family, was born in t castle of Vinci near Florence, in 1445. He was plac under Andrea Verochia, a celebrated painter in that cit but soon surpassed him and all his predecessors so muc as to be reputed the master of the third or golden age modern painting. But his studies were far from termina ing here: no man's genius was more universal; he appli himself to arts, to literature, and to the accomplishme of the body; and he excelled in every thing which he a tempted. Lewis Sforza, duke of Milan, prevailed on him be director of the academy for architecture which he had ju established, where Leonardo soon banished all the Got fashions, and reduced every thing to the happy simplici of the Greek and Roman style. By the duke's order constructed the famous aqueduct that supplies the ci of Milan with water: this canal goes by the name of *Mo tesana*, being above 200 miles in length, and condu the water of the river Adda to the walls of the city. 1479, he was desired to construct some new device for t entertainment of Louis XII. of France, who was then make his entrance into Milan. Leonardo accordingly ma a very curious automaton in the form of a lion, whi marched out to meet the king, reared up on its hinder le before him, and opening its breast, displayed an escutche with fleurs-de-lis quartered on it. The disorders of Lo bardy, with the misfortunes of his patrons the Sforzi, obli ing Leonardo to quit Milan, he retired to Florence, whe he flourished under the Medici. Here he raised the en of Michael Angelo, who was his contemporary; and R phael, from the study of his works, acquired his best ma ner of designing. At length, on the invitation of Francis, he removed to France, when above seventy years of ag where the journey and change of climate threw him in his last sickness: he languished for some months at Fo tainbleau, where the king came frequently to see him; a one day rising up in his bed to acknowledge the hono done him, he fainted, and Francis supporting him, Le nardo died in his arms. His death happened in 152 Some of his paintings are to be seen in England and oth countries, but the greatest part of them are at Floren and in France. He composed a great number of discour on curious subjects; but with the exception of his treat on the Art of Painting, none of them has been publishe

VINCULUM, in algebra, a character in form of a li or stroke drawn over a factor, divisor, or dividend, wh compounded of several letters or quantities, to conn them, and shews that they are to be multiplied or divid &c. together by the other term.

Thus $d\times\overline{a+b-c}$ shows that d is to be multiplied i $a+b-c$.

VINDHYA MOUNTAINS, a chain of hills in H dustan which passes through Bahar and Benares, and c tinues through the provinces of Allahabad and Malw along the north side of the Nerbuddah. They are in bited by Bheels, and other predatory tribes.

VINEGAR, Acetum, an agreeable acid, prepared fr wine, cider, beer, and other liquors; of considerable u both as a medicine and a sauce. The word is Fren *vinaigre;* formed from *vin*, wine, and *aigre*, sour.

VINGORLA, a town of Hindustan, belonging to t rajah of Colapoor, on the sea-coast of the province of Be poor. Long. 73. 22. E. Lat. 15. 54. N.

VIOLA. See **Botany**.

Viola, or Tenor Violin. A bow-instrument of the olin kind, intermediate in size and pitch between the olin and the violoncello. It has four strings, of which e third and fourth are covered with silvered copper wire. is tuned C, G, D, A, reckoning upwards, and is an octave gher in pitch than the violoncello, and a fifth lower than e violin. See article **Music**.

Viola, or Alto Viola, an instrument of the violin nd, larger than an ordinary violin, and furnished with four t strings, the third and fourth of these being covered with ver-plated copper wire. It originated from the *viola di accio*, one of the ancient set of viols used in concerts. ne English call it the tenor-violin, or simply the tenor. name of alto-viola is derived from its music being writ-n in the alto-clef on the third line of the stave. It is ned C, G, D, A, an octave above the violoncello. For its mpass, and use in orchestra, &c., see **Music**.

Viola d'Amore, an instrument no longer in use, but of ich the tone and effect are said to have been very sweet d singular. It was played with a bow, and seems to ve varied in the number of its strings and in its tuning. ne species of it is described as having five gut strings, d five metal wires tuned in unison with the strings, but ssing under the finger-board and bridge, and thus vibrat-g only as *open* wires, to arpeggios or harmonics, &c., play-l upon the open gut strings. The principle of this instru-ent seems to have been revived in the construction of me recent musical instruments.

Viola di Gamba, a musical instrument no longer in e, but which was the immediate predecessor of the violon-llo. A clever musician, C. F. Abel, in the last century, rew away his fine talents upon this nasal and ungrateful strument. A good *viola di gamba* affords excellent wood aterials for making a fine tenor-violin.

VIOLIN, a bow-instrument of considerable compass, d great powers of expression and execution. Its origin obscure. The best violins are those of the old Cremona akers, Jerome, Anthony, and Nicholas Amati, and Stra-varius and Guarnerius, and F. and T. and G. B. Rug-ero. Next in quality are those of Jacob Steiner, and of e two Klotz, father and son, Tyrolese makers. The dif-rence between the tone of the Cremona violins and the yrolese has been compared to the difference between the ne of a flute and a clarinet. The violin has four strings, ned G, D, A, E, reckoning upwards. The lowest string covered with fine silvered copper wire. Some persons ve used silver, or even gold wire, which does not cor-de like the copper. Gross impositions are often prac-ed by unprincipled dealers in pseudo-Cremona violins. ke *copies* of old pictures, they deceive many purchasers. any of the finest violins of the old makers have been destroy- by ignorant repairers, or by capricious alterations made the desire of ignorant amateurs. See article **Music**.

VIOLONCELLO, a powerful and expressive bow-strument of the violin family. It has four strings, the ird and fourth of which are covered with silvered copper re. It is tuned C, G, D, A, reckoning upwards, and is an tave lower than the viola. Passages of rapid execution not suit this instrument, especially on the third and urth strings. The best violoncellos are those of the old alian and Tyrolese makers. (See article **Music**.)

VIOLONE, **Contra-basso**, or **Double-Bass**, the rgest instrument of the violin kind. The best are of alian make. See article **Music**.

VIQUE, or **Vich**, a city of Spain, in the province of atalonia. It is situated on the river Tcr, above Gerona. he country around, though not naturally fertile, is render-l productive by high cultivation. The most considerable orks for printing calicos are within this district, and there e in the city considerable manufactories of cotton. The hills around it have mines of topazes, amethysts, and co-loured crystals, which are worked into ornamental jewellery by the jewellers of Barcelona, and form part of its traffic. Vique is the seat of a bishop, and has a splendid cathedral, with several other churches and several convents. It is situated in Lat. 41° 47′, and contains several monasteries, and 8400 inhabitants.

VIRAGO, a woman of extraordinary stature and courage, who has the mien and air of a man, and performs the actions and exercises of men.

VIRAGNE, a town and mud fort of Hindustan, province of Aurungabad, in the Nizam's territories, 100 miles south-east from Ahmednuggur. Long. 76. 15. E. Lat. 18. 11. N.

VIRANCHIPURA, an open town of Hindustan, in the Carnatic district of Vellore, situated on the south shore of the Palur river. It was formerly a large place, and possessed many public buildings; but suffered severely during the war with Hyder. Long. 79. 5. E. Lat. 12. 56. N.

VIRAPELLE, a town on the Malabar coast, in the district of Cochin, five miles north from the town of Cochin. It is the residence of the apostolic vicar of the Roman Catholic Christians, who superintends sixty-four churches. There are besides forty-five governed by the archbishop of Craganone, and also the large dioceses under the bishop of Cochin and Quiton, whose churches extend to Cape Comorin. Here is a convent of barefooted Carmelites, besides other Catholic seminaries. Long. 76. 10. E. Lat. 10. N.

VIRE, an arrondissement of the department of Calvados, in France. It extends over 373½ square miles, and comprehends six cantons, which are divided into 97 communes, containing 89,450 inhabitants in 1836. The capital is the city of the same name, a manufacturing place of great activity, containing 7339 inhabitants, who make annually 24,000 pieces of cloth, said to amount in value to 3,840,000 francs. It stands on the river Vire, and in the neighbourhood much cider is made, and some of it distilled to mix with brandy. It was the birth-place of the celebrated naturalist Du Hamel. Lat. 48. 50. 16. Long. 1. 0. 0. W.

VIRGIL. Of the personal history of Publius Virgilius Maro, the greatest of Latin poets, little is known with certainty. The principal authority on which his biography rests, is a life usually attributed to Tiberius Claudius Donatus, a grammarian who flourished in the fifth century of the Christian era. Its authenticity, however, is very questionable; and, at all events, it is so much disfigured by interpolations, that it is difficult to extract from it such facts as may be implicitly relied on. To this suspicious document we have to add a few scanty allusions by the poet's contemporaries, and the scattered remarks of ancient scholiasts and grammarians.

By all accounts, the parentage of Virgil is represented as exceedingly humble. Donatus informs us, that, according to some authorities, his father was originally a potter, but according to others, and those the more numerous, the hired servant of a travelling merchant, to whom he recommended himself by his faithful services, and who gave him his daughter Maia in marriage. By his father-in-law he was entrusted with the charge of a small farm in the vicinity of Mantua, which he ultimately seems to have inherited, and which probably constituted the poet's patrimony. Whatever may have been the original condition of his father, it is gratifying to find this testimony to his moral worth, and to be assured that he was capable of appreciating, and possessed the means, as well as the desire, of cultivating the rising genius of his illustrious offspring. In this respect, Virgil was equally fortunate with Horace, whose father, although possessed but of moderate fortune, placed him under the ablest masters at Rome, along with the sons of knights and senators.

Virgil was born at Andes, now called Pietola, a village about three miles distant from Mantua, in the year of Rome

684, B. C. 70, during the first consulship of Pompey and Crassus. He was thus seven years older than Augustus, and five years older than Horace. He commenced his studies at Cremona, where he remained till he assumed the *toga virilis*. This he did on entering his sixteenth year, on the very day, according to some accounts, on which Lucretius died; thus transmitting, without interruption, and with increasing splendour, the intellectual inheritance of Roman genius.

Virgil now proceeded to Milan, and from thence, after a short stay, to Naples. Here he devoted himself to study with intense application, and laid the foundation of that varied learning, for which he was no less remarkable than for poetical genius. To the language and literature of Greece he applied himself with peculiar ardour; and, in this department, enjoyed the instructions of Parthenius Nicenus, an author of some reputation. But literature alone, however varied and attractive, could not satisfy the inquisitive and capacious mind of Virgil. He strove also to penetrate the depths of philosophy and science; and medicine and mathematics continued to be favourite subjects of pursuit with him through life. Along with his friend Varius, he studied the system of Epicurus, under Syro, a distinguished teacher of that sect, and the intimate friend of Cicero. Traces of this early discipline are perceptible in his works; although by some he is represented as an academic, and as preferring the sentiments of Plato to those of all other philosophers. To some tradition of his addiction to science, to the revelations contained in the sixth book of the Æneid, and to the magic spells described in the eighth Eclogue, Virgil probably owes his reputation as a wizard, the character in which he principally figures during the middle ages.

Donatus carries Virgil from Naples to Rome, and there makes him the subject of several fabulous stories, which it would be idle to repeat. The probability is that he did not visit Rome at this time, but having finished his studies at Naples, returned directly to his paternal abode; where he continued to reside till his fame as a poet had begun to attract public notice.

Much uncertainty prevails respecting the early productions of his muse. That the Eclogues were not the first offspring of his genius, we have sufficient testimony; but the genuineness of the minor poems, which usually pass under his name, may well be questioned. The most probable conclusion is, that they are either entirely spurious, or so much disfigured by interpolators as to leave few traces of their original form. Donatus enumerates the following as youthful productions of Virgil: *Catalecton*, *Moretum*, *Priapeia*, *Epigrammata*, *Diræ*, *Culex*, and, while he admits that doubts existed respecting its authorship, *Ætna*. He is also said to have undertaken a poetical work on the early wars of Rome, but to have been deterred from the prosecution of his design, by the rugged and inharmonious structure of the ancient Italian names. To this attempt the poet probably alludes in the sixth Eclogue, where he represents himself as having prematurely undertaken a work beyond his strength. But whatever may have been the early essays of Virgil, there can be no doubt that he continued sedulously to cultivate those talents with which he was so richly endowed; and to peruse with intense admiration and delight those masterpieces of Grecian genius, which it was his great ambition to rival and excel. Nor was he inattentive to the literature of his own country; which however presented a comparatively limited field for the poetical student. Yet the works of Ennius, Plautus, Terence, Catullus, and above all, Lucretius, contained a rich poetical mine, from which much precious ore might be extracted, and to which, it is manifest, he did not scruple freely to resort. Into the genius, structure, and capabilities of his native tongue, he appears to have penetrated more deeply than any other writer; and his dictio became the standard to which succeeding poets yielded a implicit, perhaps a slavish obedience. What Cicero effect ed for prose, Virgil effected for poetry. Few literary phenc mena, perhaps, are more remarkable, than the mastery ove the Latin language, which even his earliest productions di play. In the works of preceding writers may be foun many detached passages scarcely to be surpassed; but i uniformly-sustained beauty and propriety of diction. th Mantuan bard leaves all his predecessors, as well as succe sors, at an immeasurable distance.

Virgil is usually represented as having undertaken th composition of his Eclogues at the suggestion of C. As nius Pollio, a nobleman who was not more distinguishe as a commander, than as a cultivator and patron of le ters. On the formation of the second triumvirate, A. U. 71 Pollio was entrusted by Antony, whose interests he ha espoused, with the command of Gallia Transpadana, i which district the patrimony of Virgil lay. The rising t lents of the youthful poet early attracted his notice, and l continued to extend to him his patronage and protection long as he remained in the command of the province. Th services thus generously and seasonably rendered to geniu were amply rewarded; and the name of Pollio will for ev continue associated with some of the poet's noblest strain

The date and order of composition of the Eclogues hav been matter of dispute among critics. By some they a supposed to have been written in the order in which the now stand in the printed editions, and, it is believed, in a the manuscripts of Virgil's works; by others, the secon third, fifth, and sixth are thought to have preceded the firs The determination of the question is of little importanc and our present limits forbid discussion. The subject the first Eclogue sufficiently indicates the date of its com position. After the battle of Philippi, A. U. 712, Augustu in fulfilment of a promise which had been previous given to the army, made a large division of lands amor the veteran soldiers. Cremona having espoused the cau of Brutus, was among the first to suffer on the present o casion. Its territory was assigned to the soldiers; but n proving of sufficient extent, the deficiency was suppli from the neighbouring district of Mantua. Virgil was th involved in the general calamity, and driven with violen from his humble patrimony. About this time, however, l appears to have renewed his acquaintance and friendsh with Alphenus Varus, who had been his fellow-student Naples, and who now discharged some important publ function in the poet's district. Under his protection, it supposed, Virgil repaired to Rome, and by personal app cation obtained from Augustus the restoration of his far To record his gratitude for this signal favour, he compos the first Eclogue, which, in the person of Melibœus, pr sents a vivid picture of the distress and misery by whi he was surrounded; while in that of Tityrus, he eulogis in glowing strains, and honours as a god, the youth to who he owed his own more fortunate lot. It appears, howev that he experienced no slight difficulty in recovering l farm, notwithstanding the order of Augustus; and that, one occasion, when pursued by the tribune Arrius, who h taken forcible possession of it, he saved his life by swimmi across the Mincius. To these fresh disasters he is suppo ed to allude in the ninth Eclogue. Besides Augustus, t persons chiefly celebrated in the Eclogues are Pollio, Var and Gallus, who had been the poet's earliest patrons, a who ever after continued his most esteemed and belov friends.

The Eclogues, in the composition of which he is sa to have spent three years, were received by his countrym with unbounded applause. They were universally read a admired, and such was their popularity, that they were pu licly recited in the theatre at Rome. Their novelty, storal poetry now appeared for the first time in a Roman ess; the pictures which they presented of rural felicity, d of simple and innocent pleasures, so strongly contrast- with the scenes of violence and bloodshed which had so ng deluged Italy; the descriptions of nature so exquisitely ended with human feelings and human sympathies; the usions to recent and passing events; the polished simpli- y, beauty, and harmony of the verse; all contributed to hance their merit in the eyes of his contemporaries, and establish them in popular favour.

But, however great their merit in other respects, the logues of Virgil can lay little claim to the praise of origi- lity. They are, for the most part, imitations, and occa- nally little more than translations of Theocritus. Ro- n literature was indeed essentially imitative; and its eatest masters rarely ventured to give unfettered scope the impulses of their native powers. Seldom venturing depart from their Grecian models, they were content to low closely in their footsteps, and deemed it sufficient to the in the language of Rome those ideas and descrip- ns which were furnished by their intellectual masters. t Virgil, while retaining the substance of Doric song, ceeded in impressing on his Italian transcript not a little his own calm and meditative nature, and in awakening popular sympathies of his countrymen in a manner ich at once stamped him as the national poet of Rome. t the least difficulty which he had to encounter in roducing this new species of composition, was the ap- ently intractable and inflexible nature of the language ich he had to employ, little fitted, apparently, for the scription of pastoral and rural scenes. But the pow- of the poet triumphed, in a great measure, even over s difficulty; and although unable to rival the matchless lody of the Doric reed, he imparted to his native tongue elicacy, softness, and variety, of which till then it had been nsidered unsusceptible. In estimating the immediate eption of the Eclogues, we must not altogether over- k the skill and dexterity with which the poet paid court his early patrons, whose voice was perhaps no less tential in the literary than in the political world. Their blication must, at all events, be considered an import- t era in the literary history of Rome, as exhibiting the st-fruits of that genius which was destined to stamp its lelible impress on the literature of future ages.

About the thirty-third year of his age Virgil removed to me. Here he experienced the bounty, as well as friend- p, of Mæcenas and Augustus, and appears to have been ced by their liberality in circumstances which enabled n ever after to devote his undivided energies to his fa- urite pursuits. It is pleasing to find the most cordial ation subsisting, even at this early period, between such n as Virgil and Horace. Both candidates for popu- favour, in circumstances which too frequently produce alry, if not hostility, these illustrious poets appear to have en united in the closest ties of friendship. Virgil is d to have intoduced Horace to the notice of Mæcenas; d the deep feeling of respect and admiration with which race regarded Virgil, is manifested in several parts of works. The sixth Satire of the first book exhibits a asing picture of the intimate terms on which they lived h their common patron Mæcenas, and with some of ir poetical contemporaries. During his residence at me, Virgil inhabited a house on the Esquiline hill, near gardens of Mæcenas. He was treated with universal pect; and on one occasion, when some of his verses re recited in the theatre, the whole audience rose to sa- e him, with the same respect that they were ac- stomed to bestow on the emperor. But his modesty unk from the public gaze; and amid the splendour and mage of Rome, he longed for scenes more in harmony h his poetical and contemplative genius, and, it may be added, better suited to the delicacy of his constitution. After a brief sojourn in the metropolis, he accordingly retired to Naples, at that time the favourite retreat of literary men; and there, or at a delightful residence in the vicinity of Nola, about ten miles distant, he continued chiefly to reside during the remainder of his life.

Having thus chosen a congenial place of abode, Virgil, at the suggestion of Mæcenas, commenced the composition of the *Georgics*. The subject was selected, we are told, with the view of restoring among the Romans a love of those rural pursuits to which they had been peculiarly addicted in early times, but which, amid the desolation and bloodshed of the civil wars, had been entirely abandoned and forgotten. Little is known of the private life of Virgil during the composition of this immortal poem, which occupied the space of seven years. Donatus and others relate, that he was accustomed to dictate a number of verses in the morning, and spend the day in polishing and reducing them to a smaller number. From internal evidence, this appears to be no inaccurate description of his literary habits.

The Georgics more than realized the highest expectations that had been formed of Virgil's poetic powers. This work, which is dedicated to Mæcenas, is divided into four books, and treats in succession of husbandry, planting, cattle, and bees. Our limits forbid any attempt at analysis; nor indeed could words convey any adequate notion of the wonderful union which this masterwork presents of didactic precept, varied and splendid description, touching pathos and sensibility, episodes at once appropriate and striking, historic and mythologic allusion, displaying all the resources of the richest poetical treasury. The sweetness and easy flow of versification by which the Eclogues are distinguished, gave but faint indication of the matchless power, variety, and magnificence of the Georgics. Although the subject of this poem is peculiarly national, yet the same imitative spirit which pervades the whole literature of Rome, exercised its influence here also. As in the Eclogues Theocritus, so here Hesiod formed the chief model for the general structure and conduct of the work. But in this poem Virgil perhaps owes less to his prototypes than in his other productions; and he has diffused over the whole a flood of poetical light peculiarly his own. The poet has indeed exhibited the happiest combination of genius and art, and has succeeded in imparting to didactic themes a life, an interest, and a grandeur, of which, from their nature, they seem scarcely susceptible. Here the Romans found scenes and modes of life in which their fathers had delighted, depicted in colours which could not fail to excite the deepest interest, and rekindle in their breasts the love of pursuits, which, though for a time banished by the rude collisions of civil strife, were associated in their minds with the heroes and patriots of old, with the undying achievements and illustrious characters of ancient times. In estimating the merits of the Georgics, we must not pass without special notice the matchless beauty of the versification. In sustained majesty, in melody that ever satisfies but never cloys the ear, in variety of modulation, in stateliness but freedom of march, it stands unapproached by any other Roman poet, and unsurpassed by Virgil himself.

Having with such signal success enriched the literature of his country with two species of poetry, of which till then it possessed no example, he resolved to attempt a work of a still higher nature. It is evident that he had long meditated such a work; as we find allusions to it both in the Eclogues and Georgics. He commenced the *Æneid*, A. U. 724, the year in which he completed the Georgics. This great work, undertaken, we are told, at the request of Augustus, occupied him till his death, and even then had not received his finishing touch. As he proceeded with its composition, the greatest interest was excited respecting it, and the highest expectations were entertained of its merits, as may be gathered from the prognostication of Propertius, who thus anticipates its future fame:

> Cedite Romani scriptores, cedite Graii,
> Nescio quid majus nascitur Iliade.

In 729, Augustus expressed a strong desire to be favoured with a perusal of the poem, so far as it had been completed; but Virgil excused himself, on the ground that the work was not yet worthy of such an honour. About a year afterwards, however, he was prevailed on to read the sixth book to Augustus, in the presence of his sister Octavia. When the poet reached the beautiful passage in which he alludes so pathetically to the death of her son Marcellus, the adopted child of Augustus, and the universal favourite of Rome, Octavia is said to have swooned away; and, on reviving, to have ordered the poet to be rewarded with ten *sestertia* for each line. In conformity with the usual practice among Roman poets, Virgil occasionally recited portions of his verses to his literary friends; not, however, for the sake of display, but in order to be favoured with their critical remarks. His recitation is represented as highly effective, and as distinguished by remarkable sweetness, and propriety of articulation.

Having completed the Æneid, he resolved to travel into Greece, that he might, at leisure, correct and polish his great work, and bring it to the greatest possible perfection before giving it to the world. On this occasion, Horace addressed to him the beautiful ode, beginning, "Sic te diva potens Cypri;" in which he expresses in the most affectionate terms, his anxiety for the safe return of his beloved friend. On arriving at Athens, Virgil proceeded to execute the task which he had imposed upon himself; and, besides, composed the splendid introduction to the third book of the Georgics. His original intention, on quitting Italy, was to dedicate three years to the work of revisal, and then, amid the scenes of his native country, to devote the rest of his life to the study of philosophy, in which he had always delighted. Augustus, however, on his return from the East, having reached Athens, Virgil, probably in consequence of the state of his health, resolved to accompany him to Rome. But his days were now numbered. The vessel in which he sailed along with the emperor, touched at Megara, where he was seized with extreme debility; and his distemper increased so much during the remainder of the voyage, that he died a few days after reaching Brundusium. This event took place, A. U. 735, in the fifty-first year of his age. In compliance with his dying wishes, his bones were conveyed to Naples, where, in literary seclusion, he had spent so many years of his life; and his tomb is still pointed out at a spot about two miles distant from that city. The urn which was supposed to contain his ashes, bore the following inscription, which is said, but without sufficient authority, to have proceeded from the lips of the dying poet:

> Mantua me genuit; Calabri rapuere; tenet nunc
> Parthenope: cecini pascua, rura, duces.

The precise locality of Virgil's tomb has been made the subject of controversy; but there seems to be no good reason for rejecting the common tradition of the country on this point. He bequeathed the greater part of his wealth to his brother; the rest, to Augustus and Mæcenas, and his friends L. Varius and Plotius Tucca.

Virgil is represented as tall of stature, of a swarthy complexion, negligent in his dress, and somewhat ungraceful in his deportment. The melancholy with which he was tinged probably arose from the delicacy of his constitution, and the ill health under which he laboured. Of the native warmth of his heart, and the sincerity of his friendships it is impossible to doubt, since he was universally beloved as well as admired by his contemporaries; who, amid their mutual jealousies and literary rivalry, seem to have united in doing honour to one, who ever cheerfully recognised the merits of others, rejoiced in, and, to the utmost of his power, promoted, success. Of the more private and familiar life of Vi nothing is known. Unlike Horace, whose works consti his best biography, Virgil has few allusions to himself, none that throw light on his domestic habits. He pa before us with much of the indistinctness and shad grandeur in which he envelopes the shades in Elysium

When he perceived his end approaching, he is to have ordered Varius and Plotius Tucca to burn Æneid, on which he had expended so many years' lab and on which his future fame was expected mainly to The reason of this command has been the subject of m discussion. The common opinion is, that not having ceived his finishing hand, he was unwilling to transm posterity and peril his fame on a work, which he had brought to that degree of perfection which he had cont plated. Some, again, account for the poet's conduct the supposition that, on the approach of death, he felt gret at having produced a work which, instead of inspi sentiments of liberty, was intended to reconcile his c trymen to the chains which had been imposed upon t by a successful but unworthy usurper. Fortunately fo interests of literature, Augustus interposed his auth to save a poem, to the completion of which he had lo forward with intense interest, and from which he an pated so much glory to himself and the Roman state. was intrusted to Varius and Tucca for revisal and p cation, but with express injunctions that they should no additions to the words of the poet; and we have son to believe that they executed their honourable in a spirit of due reverence for departed genius.

The Æneid, as already mentioned, excited the hig expectations among the literary contemporaries of the during its composition; and on its publication, was h with universal approval. Ovid alludes to it more than in terms expressive of his conviction that it occupied first place in Roman literature, and that, in common the other works of the author, it would last while the nal city should endure. The sentence thus early prono ed, has been confirmed by the consenting voice of ceeding ages; and, whatever difference of opinion may existed respecting its comparative merits, the Æneid ever been ranked as one of the rare productions of hu genius, which are destined to immortality. If consid as the rival of the Iliad, the Æneid will be present a false as well as unfavourable point of view; and it is cult to conceive that it was composed under any such dominating idea. Neither the age which produced it, the genius of the poet, was favourable to such an achi ment; but having resolved to compose an epic poem, V no doubt took Homer as his model, and endeavoure transplant into the fabric of his work as many of the b ties of the Grecian poet as suited the nature of his sub We accordingly find that he drew equally on the Iliad Odyssey, the first six books being on the model of former, and the remaining six on that of the latter. far his plan was adopted with a view to avail himse the whole range of Homeric materials, it is difficult to termine; but it was a bold attempt, if it was ever con plated, to rival or surpass in a single work, the comb excellencies of his matchless models.

The chief design of the Æneid appears to have bee deduce the origin of the Romans from the Trojans, an tracing the family of Augustus to Æneas, to establis divine title to the sovereignty of Rome. This leading pervades the whole texture of the work; and the rest which was thus necessarily imposed on the poet, must interfered most unfavourably with the freedom of movement. The character of Æneas is meant to sh forth that of Augustus; but while he constantly occu

Virgil.

e fore-ground, he is invested with few attributes calcu-ted to excite admiration, or awaken a vivid interest in his reer. He is represented as the mere passive instrument fate, and there is consequently little about him of heroic ring. The Romans, however, could not fail readily to cognize the intended resemblance; and the halo thrown ound the hero of the Æneid, was calculated to reconcile em to the destined sway of his descendant, which had en mysteriously announced by oracles.

We cannot enter into the details of the Æneid, or point t the manner in which the poet has accomplished his main sign. As might be expected, he has availed himself of l the native, as well as foreign resources within his reach, hile the whole displays that sober and chastised judgement r which he was so remarkable, and which, in his case, s so admirably combined with high poetical genius. The neid has been generally censured for want of variety in e characters. That this charge is well-founded, must to certain extent be allowed; but the fault is inseparable m the very design and structure of the work. The chief ject being the exaltation of Augustus, no formidable com-titor could be admitted on the scene. The whole atten-n is fixed on one central figure, to which all the others e made subordinate. But although the contrasts of cha-cter are not glaring, they are frequently not indistinctly arked; and if they are apt to elude the notice of the reless observer, they reveal themselves with sufficient earness to the more searching and curious eye. But the eat merit of the Æneid lies, not in its leading design and neral conduct, but in the beauty of its details; many which will bear comparison with the happiest inspira-ns of the father of epic song. It may not be improper remark, that Virgil, amid the fulsome homage and adula-n, which, in common with the other poets of that age, bestows on Augustus, frequently displays a truly Ro-an spirit; and, from the manner in which he represents e agents and events of the olden times, appears to sym-thise with, and appreciate, the sterner and nobler virtues which Rome was distinguished, while the genius of free-m yet presided over her destinies.

In the composition of his works, Virgil drew unsparingly, t only on the poetic treasures of Greece, but on the more nited resources of his native literature. This however he l in conformity with the universal practice of his coun-ymen; and it may with truth be affirmed, that he bor-wed nothing which he did not adorn. His imputed pla-arisms have sometimes been pointed out with a malicious dustry; but when properly viewed, with reference to e position and mission of the poet, they will be found to ove at once the soundness of his judgment, and the rity and refinement of his taste.

The general character of Virgil as a poet may be con-lered as fixed by the concurring testimony of critics of l ages. That he was deficient in the highest attribute genius, in the power of creating and bodying forth ori-nal conceptions, must be admitted; but, with this limi-tion, there are few qualities in which he will be found nting. In soundness of judgment, and correctness of ste; in depth and tenderness of feeling; in chastened ncy and imagination; in vivid and picturesque descrip-n; in the power of appreciating and pourtraying the autiful, whether in nature or art; of depicting passion, d touching the chords of human sympathy; in matchless auty of diction, and in harmony and splendour of versi-ation, he stands alone among the poets of his own coun-y, and will bear a favourable comparison with those of y other. His works have taken their place among the perishable offspring of genius, and, while literature lasts, ll continue to exercise a powerful influence on the po-ical taste of successive generations.

Virgil, Virginia.

The *editio princeps* of Virgil was printed at Rome, by Sweynheym and Pannartz, *sine anno*, most probably 1469. Of the immense number of editions which have succeeded it, we must content ourselves with mentioning the following, as among the most valuable. N. Heinsii, Amst. 1676, 12mo. Ruæi, in usum Delphini, Par. 1675, 4to; often reprinted. Emmenessii, Lugd. Bat. 1680, 3 tom. 8vo. Masvicii, Leovard. 1717, 2 vols. 4to. Burmanni, Amst. 1746, 4 tom. 4to. Heynii, Lips. 1803, 4 tom. 8vo. A new edition of Heyne's Virgil has lately appeared, with valuable critical additions by Wagner, Lips. 1830–2, 4 tom. 8vo. A fifth volume is announced to complete the work. Hunteri, Cupri Fif. 1810, 2 tom. 8vo; remarkable for the accuracy of its text. Forbigeri, Lips. 1836–9, 3 tom. 8vo.

Of the English translations of Virgil, that of Dryden is the most popular. A translation of the *Eclogues* and *Georgics* by Warton, and of the *Æneid* by Pitt, appeared in 1753, 4 vols. 8vo. These are held in high repute. The Æneid has also been translated into English verse by Symmons and Ring; and into Scotish verse by Gawin Douglas, bishop of Dunkeld. Of this last work, an excellent edition was published by Ruddiman, Edin. 1710, fol.; but a still more valuable edition, in 3 vols. 4to, is now printing for the Bannatyne Club, under the superintendence of George Dundas, Esq. Of the Georgics, Sotheby's translation is incomparably the best. D. K.

VIRGIL, *Polydore*, an English historian, born at Urbino in Italy, was sent in the beginning of the sixteenth century by Pope Alexander VI., as sub-collector of the papal tax called *Peter-pence* in this kingdom. He had not been long in England before he obtained preferment in the church; for in 1503 he was presented to the rectory of Church-Langton, in the archdeaconry of Leicester. In 1507 he was collated to the prebend of Scamlesby, in the church of Lincoln; and in the same year was made archdeacon of Wells, and prebendary of Hereford. In 1513, he resigned his prebend of Lincoln, and was collated to that of Oxgate in St Paul's, London. We are told, that on his preferment to the archdeaconry of Wells, he resigned the office of sub-collector to the pope, and determined to spend the remainder of his life in England, the History of which kingdom he began in the year 1505, at the command of Henry VII. That work cost him twelve years' labour. In 1526, he finished his treatise on Prodigies. Polydore continued in England during the whole reign of Henry VIII., and part of that of Edward VI., whence it is concluded that he was a moderate Papist. In 1550, being now an old man, he requested leave to revisit his native country. He was accordingly dismissed with a present of 300 crowns, together with the privilege of holding his preferments to the end of his life. He died at Urbino in the year 1555. As an historian, he is accused by some as a malignant slanderer of the English nation; yet Jovius remarks, that the French and Scotish accuse him of having flattered that nation too much. Besides the above work, he wrote, 1. *De Rerum Inventoribus;* of which an English translation was published by Langley in 1663. It was also translated into French and Spanish. 2. *De Prodigiis et Sortibus.* 3. *Episcoporum Angliæ Catalogus.* Manuscript. 4. *De Vita perfecta*, Basil. 1546, 1553, 8vo. 5. *Epistolæ eruditæ;* and some other works.

Boundaries.

VIRGINIA, the largest and most central state in the American Union, perhaps the most varied in its productions, and the richest in natural resources, blessed with a happy climate and a fruitful soil, exhibiting a pleasant interchange of the most romantic and lovely scenes. The state borders upon the Atlantic ocean and the river Ohio, extending from 75° 10′ to 83° 25′ W. Long., having Maryland on the east, and Ohio and Kentucky on the west: on the north are Maryland and Pennsylvania, and on the south Tennessee and North Carolina. Its general breadth from north to south is about 200 miles, its length in the southern part is from 400 to 430 miles, and, north of 38°, about half that extent; its area is about 70,000 square miles, being but little inferior to Scotland and England united.

Mountains. With the exception of Pennsylvania, Virginia is the only state that extends quite across the great Appalachian chains, and it is traversed from north to south by several well-defined mountain ranges. Our knowledge of the course and connections of these chains, which have not been accurately laid down in maps, is yet very imperfect, but some of them have been traced with tolerable precision. The Blue Ridge, although pierced by the Potomac, James, and Staunton rivers, constitutes a well-marked and continuous chain of 260 miles in length. In general it forms rounded, swelling masses, about 2000 feet above the level of the sea, or about 1500 feet above the valleys at its eastern base; but the Peaks of Otter shoot up in projecting summits to the height of 4260 feet. The prolongation of the Kittutinny mountain of Pennsylvania, enters the state in Morgan county, under the name of the Great Ridge, or North mountain, and passes into North Carolina under the name of the Iron mountain. Its height is generally from 2100 to 2500 feet, but the White Top peak reaches the height of 6000 feet. The Great valley, which lies between these two ridges, sometimes called the German valley, is a continuation of the Cumberland and Tulpehocken valleys of Pennsylvania. Through this ridge the New river passes westward, and the James and Potomac eastward. West of this are numerous mountain masses, which are probably prolongations of those which traverse central Pennsylvania.

Rivers. Every portion of Virginia is traversed by fine rivers and streams, useful either as channels of navigation or for manufacturing purposes. The chief of these is the main trunk of the Potomac, which has already been described under the article MARYLAND. Its principal tributaries are from this state. The Rappahannock rises on the eastern side of the Blue Ridge, and is navigable for small vessels to Fredericksburg, 110 miles. James river is by far the largest and most important of the streams which have their whole course in Virginia, and is not inferior to the Potomac and the Kanhawa in utility and the varied beauties of its scenery. Rising in the Alleghany mountain, it first bears the name of Jackson's river, and after having received the Cow Pasture river, a considerable stream, it takes the name of King James, passes through the Kittutinny, and several other mountain chains, enters the great valley, and, gathering the waters of that fruitful region, emerges from the Blue Ridge over the Irish Falls. Above Richmond it descends by a fall of seventy feet, in the distance of eight miles, into the low country. Below Richmond it gradually becomes wider and deeper, and in the lower part of its course expands into a long, spacious bay, with sufficient depth for the largest ships. Vessels of 600 tons ascend to City Point, seventy-five miles from the bay, although there are some bars and shoals which obstruct the navigation; and vessels drawing fifteen feet of water proceed thirty miles higher, to Warwick, which is within five miles of Richmond, the capital of the state. The Blackwater, Nottoway, and Meherrin, unite in North Carolina to form the Chowan, which enters Albemarle sound. They are all navigable for small coasting vessels. The Great Renawha, and the other rivers of the western section, all reach the Ohio.

Minerals. The geological formations of this vast region have as yet been but very partially explored. The mineral wealth of Virginia is almost boundless; gold, copper, lead, iron, coal, salt, limestone, marls, gypsum, magnesian, copperas, and alum earths, excellent marbles, granites, soapstones, freestones, &c., are among its subterraneous treasures. The first coalfield is that of the primary region, the extent of which has not been determined, but indications of coal have been traced from the South Anna, near its mouth, to Prin Edward, south of the Appomattax. The thickness of t coal-seams is very variable, ranging from four or five thirty, forty, and even sixty feet; the coal is bituminou and of an excellent quality. On the north branch of t Potomac there is a remarkable bituminous coalfield. Up a stratum of valuable iron-ore, not less than fifteen feet thickness, there rests a bed of sandstone, upon which repos a coal-seam three feet thick; upon this, another bed sandstone, then a two feet vein of coal; next sandston then another coal-seam of four feet; again a stratum sandstone, and over it a seven feet vein of coal; over t a heavy bed of iron-ore, and crowning the series an eno mous coal-seam from fifteen to twenty feet in thickne West of the Alleghany, there are some of the most exte sive and valuable deposits of coal in the world. At Whee ing, on the Ohio, and for fourteen miles down the rive the bank presents an uninterrupted bed of highly bitun nous coal, upwards of sixteen feet thick. Salt springs occ in various places. But the most important works are the Great and Little Kanawha. Gold is at present t most important of the metallic minerals of Virginia. occurs throughout a belt on the western side of the prima district, stretching from beyond the Rappahannock to t Appomattax. Most of the gold hitherto obtained h been procured by washings from the deposit-mines, b several veins have yielded rich returns. In 1803, at Rei mine, a negro found one lump that weighed twenty-ei pounds avoirdupois, worth eight thousand dollars. T largest piece of gold in one mass, ever found in Euro weighed only twenty-two ounces; and this was found Wicklow in Ireland. But the mines in Virginia are n ther extensively worked, nor fully developed. For seve years they have been left to the enterprise of the farme or owners of the soil, who occupy themselves with mini when not engaged on their farms; and it is calculated t the product of the mines in this section of the count will amount to about L.80,000 annually.

Iron will probably at some future day prove to be a m precious deposit; but, although the ore of several variet is lavished in profusion on different sections of the sta it is at present but little worked. Copper-ores are fou among the altered rocks east of the Blue Ridge; and n merous openings have been made in Orange, Amher Campbell, and Buckingham, for procuring the cupre rock, which at an early period was ground on the spot, a sent to England to be smelted. Lead occurs in the sout western part of the state, in the forms of the sulphu (galena) and carbonate, both of which are wrought, yie ing a large per centage of valuable metal.

A continuous line of railway is nearly completed acr the state, from the Potomac to the Roanoke. The Ric mond and Potomac railroad extends from Potomac cre in Stafford, through Fredericksburg, to Richmond, sever miles, having been completed in 1836. Railroads a canals cross the state in every direction, affording rea and convenient means of communication for all purpose

Agriculture has always been the chief occupation of t inhabitants, but not to the exclusion of other branches industry. " There is a great diversity in the agriculture the state, but it is seldom well managed. On both sides the Blue Ridge, maize, or Indian corn, wheat, rye, oa and buckwheat, are the principal grain crops. Tobacco the principal staple of most of eastern Virginia, but in t valley it is cultivated only in the southern portion, and n at all beyond the Alleghany. In the eastern and southe counties cotton is planted to a considerable extent. (the shores of the Chesapeake, barley and the castor bean are cultivated; and on some of the best lands ab tide-water, hemp is raised to advantage. The Trans- leghany county, being exceedingly mountainous and ote from market, is chiefly devoted to raising live stock. o more grain is raised than is sufficient to supply the unty itself. The culture of tobacco was begun as early 1616, and that plant soon formed the staple production the colony. During the latter half of the last century, annual export amounted to 60,000 or 70,000 hogs- ads; of late years the amount produced in eastern Vir- ia has fallen off considerably, on account of the exhaus- n of much of the land suited to this crop; but its culti- ion has been much extended beyond the Blue Ridge. e manufactures of Virginia are by no means inconsider- le in value and extent, but they are not in general of the ss which involves the nicer and more complicated pro- sses of art, consisting rather of those simpler operations, ich convert the native growth of the forest, the products the mineral kingdom, or the fruits of agricultural labour, o articles of home consumption or commerce. The fo- ts and the coal-beds furnish a cheap and easy supply of l, and the numerous water-falls offer an almost unlimited tive power for economical purposes; and within the last v years several cotton mills have been erected for spin- g and weaving, in which white operatives have sought ployment. The exports of Virginia consist chiefly of icultural products; lumber, salt, castor oil, ginseng, coal, ld, some furs, &c. The value of the direct exports to eign countries in 1836, was 6,192,040 dollars, but the in- nal American trade must exceed that sum. The im- rts from foreign ports amounted in the same year to only 106,814; but Virginia receives her supplies of manufac- red goods and foreign productions chiefly from northern rts. The fisheries of the Chesapeake and its tributaries valuable. The shipping owned in the state amounts to ,000 tons."

The first white settlers in Virginia were English; and e emigration from England continued to be pretty active ring a great part of the seventeenth century, particularly om the time of the civil wars to the Restoration, in 1660, d toward the close of the century, both before and after e Revolution. Many victims of the political disturbances those periods were also sent to Virginia as servants; and e captives at Worcester, the followers of Penruddoc, the sh catholics, and the soldiers of the duke of Monmouth, re sold into servitude in the colony. In the following ntury, many German emigrants, chiefly from Maryland d Pennsylvania, occupied the valley in the rear of the ue Ridge, which thence received the name of the Ger- an Valley; and in the more western part of the state, eat numbers of Irish settlers fixed themselves; and me felons were transported to Virginia, as to other colo- s. Negroes and mulattose constitute a large proportion the population of Virginia, and these are mostly held in very. The first negroes were brought into the harbours the Chesapeake by a Dutch ship in 1620, when twenty re sold to the colonists; but the importation was for a g time so inconsiderable, that at the end of fifty years ir number was only 2000. The inhabitants indeed en- avoured to discourage the traffic, and the Assembly made eated attempts to prevent the further introduction of groes, but failed in obtaining the requisite sanction of crown; and up to the time of the revolution-war, from 00 to 6000 were annually brought into the province by English slave-traders. It is one of the grievances re- ed in the constitution of 1776, and reaffirmed in the w instrument adopted in 1830, that George III. had ompted the rising in arms of "those very negroes whom, an inhuman use of his negative, he had refused us rmission to exclude by law;" and in 1778 the new te prohibited their importation under heavy penalties. he existing black population of Virginia is probably al- gether native.

Population at different periods.

	Whites.	Slaves.	Free Blacks.	Total Blacks.	Total.
1642	...	...	...	...	20,000
1670	38,000	2,000	...	2,000	40,000
1790	442,115	293,427	12,766	306,193	748,308
1800	514,280	345,796	20,124	365,920	880,200
1810	551,534	392,518	30,570	423,088	974,622
1820	603,074	425,153	37,139	462,292	1,065,366
1830	694,300	469,757	47,348	517,105	1,211,405

Besides the loss of population, occasioned by the removal of free labourers and of planters with their forces, the sale and exportation of slaves to other states have been a constant drain to this class of the population, especially during the last ten years. Virginia has the unenviable distinction of being a slave-breeding state, not only supporting slavery within its own limits, but contributing to extend it in other states of the Union. This unnatural and disgusting trade must infallibly demoralize both the white and coloured population; and as a proof of the suffering which it entails upon its wretched victims, no less a sum than 14,412 dollars is stated in the account of the public expenditure of the state for 1833 for *transported and executed slaves;* while the next item, the public guard, amounts only to 19,225 dollars.

A few families of Indians of the Nottoway tribe, a branch of the great Iroquois family, are still found on the river of that name, but they have lost the language of their fathers, and have become much mixed with negroes. Of the thirty Powhatan clans found here by the first colonists, not one is believed to survive.

Richmond, the capital of the state, and its principal city, is pleasantly situated on the left bank of the James, below the lower falls, standing on several eminences, which command fine views of the surrounding country, and give to the city an air of singular beauty. Richmond was declared the capital of the state in 1779, and incorporated as a city in 1782, when however it was merely a small village. In 1800 the population was 5,737, and in 1830 it was 16,060, more than one half blacks; at present, inclusive of Manchester, which is united with it by a bridge, it exceeds 20,000. Richmond is 110 miles from the mouth of the river, which carries fourteen feet of water to Warwick, five miles below the city, and is navigable for boats 220 miles above the falls.

Educational institutions.

Such was the state of education in the colony, that one of the early governors thanked God that there were no free schools or printing in Virginia. In 1796, an act was passed for the establishment of primary schools; but in 1809 the governor complained that the law had in no instance been complied with. In that year a literary fund was created by the appropriation of fines, escheats, and forfeitures, to this object; and the money received by the state from the federal government in 1816, for military services rendered during the late war, was afterwards appropriated to the same purpose. In 1833 the fund amounted to 1,551,837 dollars, and the income to 78,340 dollars. In 1817 a permanent appropriation was made of 45,000 dollars a-year from this revenue, to be distributed among the several counties and towns, in proportion to their free white population, for the instruction of poor children, and an additional sum was granted for the same object in 1836. In 1833, by returns from one hundred counties, there were 2833 common schools, attended by 17,081 poor children. In order to extend the benefits of this system to all classes of whites, the school-commissioners of any county are authorised to lay off the county into school-districts, and, whenever any district shall have raised three-fifths of the

Virgin Islands. sum necessary to build a school-house, to contribute the remaining two-fifths. They are also empowered to pay a sum not exceeding one hundred dollars towards a teacher's salary, provided the inhabitants of the district contribute an equal sum towards the same object; and every white child in such district is to be gratuitously taught in such school. There are about fifty-five academies in the state. The higher educational institutions are the university of Virginia at Charlottesville; the college of William and Mary at Williamsburg; Washington college at Lexington, Bockbridge county; Hampden-Sydney college in Prince Edward county; Randolph-Macon college at Boydton, Mecklenburg county; the Union theological seminary in Prince Edward county; the Episcopal theological seminary near Alexandria; and the Virginia Baptist seminary near Richmond. In 1839 there were fifty-two newspapers published in Virginia.

Legislature. The legislature, styled the General Assembly, consists of two houses; a house of delegates of 134 members, chosen annually; and a senate of thirty-two members, chosen for the term of thirty-four years. Senators and delegates must be resident freeholders; the latter of the age of twenty-five years, the former of thirty. All laws must originate in the house of delegates. The governor and the council of state, of three members, are chosen by the joint vote of both houses of the assembly, for the term of three years, the senior councillor being lieutenant-governor. The superior judges are chosen by the same bodies, and hold office during good behaviour. The justices of the peace are appointed by the governor on nomination, by the existing justices of the respective counties, and one of their number performs the duties of sheriff. A small property qualification is required to confer the right of suffrage on white male citizens; and at all elections "the votes must be given openly, or *viva voce*, and not by ballot."

Revenue. The revenue of the state for the year 1834, was 403,335 dollars, of which 291,581 dollars were derived from taxes on land, slaves, horses, and carriages, and 101,283 from licences, making, with the balance of 185,221 dollars in the treasury at the close of 1833, a total of 588,556 dollars. The expenditure, during the same year, amounted to 472,337 dollars; some of the principal items, exclusive of payments from literary and other funds, being as follows:

General assembly	90,141	Transported and executed slaves	14,412
Officers' salaries	78,815	Public guard	19,225
Judiciary	22,625	Penitentiaries	23,911
Criminal charges	32,240	Lunatic asylum	34,500
Revolutionary half-pay officers	12,166	General appropriations	24,417

VIRGIN ISLANDS, situate between 17° 40′, and 80° 40′ N. lat., and between 64° 30′ W. long. Sir Francis Drake is said to have called them the Virgin islands in honour of Queen Elizabeth; but this is a mistake, for they were called Las Virgines by Columbus, in honour of the eleven thousand virgins in the Romish ritual. The principal of these is Santa Cruz, a Danish possession about twenty-one miles long, and about five broad, which has an area of more than 100 square miles. It is one of the best cultivated islands in the West Indies. Sugar is its staple commodity. The population of the island is reckoned at 32,000. St Thomas, another Danish island, about twelve miles long, with an area of about fifty square miles, possesses a safe and capacious harbour, and carries on a considerable trade. The population amounts to about 8000. St John's is the only other possession of Denmark in this group of any importance. Its population is about 2500.

The principal British islands are Tortola, Virgingorda, and Anegada. The exportable products chiefly consist of sugar and molasses. Tortola is about twelve miles long and four broad. Anegada and Virgingorda are each about t miles long. Besides a number of very small islands, Cul bra or Passage island, and Vieque or Crab island, belo to Britain. The latter is sixteen miles long and four broa but is uninhabited. The British, Danes, and Spaniards ha the right of cutting wood in it, and fishing on its coas The climate is more healthy than in the average of the We India islands. Excepting Tortola, the other islands conta a very small number of inhabitants.

The population of these three islands in 1835, consisted

VIRGO, one of the signs or constellations of the zodi

VIRNANGH, a village of Hindustan, in the province Cashmere, thirty-seven miles south-east from the city Cashmere. Long. 74. 13. E. Lat. 34. N.

VIRTUAL, or POTENTIAL, something that has a pow or virtue of acting or doing. The term is chiefly unde stood of something that acts by a secret invisible cause, opposition to actual and sensible.

VIRTUE, a term used in various significations. In general sense it denotes power, or the perfection of a thing, whether natural or supernatural, animate or inan mate, essential or accessory. But, in its more proper or r strained sense, virtue signifies a habit, which improves a perfects the possessor and his actions.

VIRTUOSO, an Italian term introduced into Englis signifying a man of curiosity and learning, or one w loves and promotes the arts and sciences. But amo us the term seems to be appropriated to those who app themselves to some curious and quaint rather than imm diately useful art or study; as antiquaries, collectors of r rities of any kind, microscopical observers, &c.

VISCOUNT (*Vice Comes*), was anciently an officer u der an earl, to whom, during his attendance at court, acted as deputy to look after the affairs of the county. B the name was afterwards employed as an arbitrary title honour, without any shadow of office pertaining to it, Henry VI.; when, in the eighteenth year of his reign, created John Beaumont a peer by the name of Viscou Beaumont, which was the first instance of the kind. A v count is created by patent. His mantle is two doublin and a half of plain fur, and his coronet has only a row pearls close to the circle.

VISHNOU, that person in the triad of the Brahmins w is considered as the *preserver* of the universe. *Brah* is the creator, and *Siva* the destroyer; and these two, w Vishnou, united in some inexplicable manner, constitu *Brahme*, or the supreme numen of the Hindus.

VISIER, an officer or dignitary in the Ottoman empi The *Visier-azam*, that is, "grand visier," is the prime r nister of state in the whole empire. He commands the arı in chief, and presides in the divan or great council. N to him are six other subordinate visiers, called *visiers of bench*, who officiate as his counsellors or assessors in divan.

VISTULA, or WEISEL, a large river of Poland, whi taking its rise in the mountains south of Silesia, visits C cow, Warsaw, &c. and continuing its course northward, fa into the Baltic sea below Dantzig.

VITERBO, a delegation or province of the papal minions, formed out of a part of Orvieto, the duchy Castro, and the countship of Ronaglione. It is bound on the north by Perugia, on the north-east by Spoletto, the east by Rieta, on the south-east by Rome, and on t south and south-west by the sea, and on the west by a p of Tuscany. The face of the country is in the north mo tainous, in the middle undulating, and on the west a le

Vitry-le-Francais || Vizagapatam.

lain. With Civita Vecchia, it extends over 1716 square iiles, and comprehends 13 cities, 24 market-towns, and 76 villages, with 145,022 inhabitants. The chief products e wine, corn, olive-oil, and live cattle, all of which are atnded to with great ignorance and indolence. The capil is the city of the same name. It stands on a plain at the ot of the mountains, is surrounded with ancient walls id towers, has straight and broad streets well paved with va, a fine market-place, and many magnificent buildings. is the seat of a bishop, and besides the cathedral, has 16 irish churches, in one of which, that of Santa Rosa, are me most valuable paintings, executed by Sebastiano Piomno. The population amounts to 13,100, employed in vaous trades, one of the most extensive of which is refining ltpetre. In the neighbourhood are sulphureous baths of eat celebrity ; and near the city, in the church of Madona ll Quercia, is an image to which numerous pilgrimages are inually made. Lat. 42. 24. 54. Long. 27. 59. 25. E.

VITORIA, a city of Spain, in the province of Alava. is built on the river Ladorra, which runs into the Ebro, a plain which yields excellent wheat and other grain, it is surrounded with lofty and barren mountains. The alls round it are unfit for defence, but they render the ty compact, and furnish very pleasant public walks. It is a large collegiate church, and several other religious iildings. The population amounts to about 8000, who are enerally an industrious description of people. It has often een the theatre of war, and the celebrated battle gained iere by the duke of Wellington, will transmit its name to stant ages. It is situated in Lat. 42. 53. 30.

VITTORIA, a city of the kingdom of Naples, in the land of Sicily. It is in the province of Noto, and is the ipital of a circle of it called the Contea of Modica, which ntains 120,000 acres of land, and 80,000 inhabitants. It 130 miles from Palermo, and is oddly situated among raggling craggy rocks, but boasts of a few fine edifices. It the seat of an independent local court of justice, and one the parliamentary cities. It is rather an unhealthy place, ut contains 10,000 inhabitants, who are chiefly occupied agriculture, rear a great number of horned cattle, and roduce a large quantity of silk. It likewise yields much ax and honey.

VITRIOL, a compound salt. formed by the union of on, copper, or zinc, with sulphuric acid ; hence called om the colours white, blue, and green, according to the etal.

VITRIOLATED, among chemists, something impregated, or supposed to be so, with vitriol or its acid.

VITRUVIUS Pollio, Marcus, an ancient architect great name, is sometimes represented as a native of ome; but, if we may rely on the opinion of Maffei, there e divers reasons for supposing him to have been a native Verona ; and other writers are disposed to transfer the onour of his birth-place to Formiæ, a city of Campania, nd now called Mola di Gaeta. His *prænomen* is not less oubtful than his country. In the first edition of his work, e is called Lucius. A. appears in some manuscripts, but I., or Marcus, is most frequently to be found. Of his peronal history, any notices which we possess are almost enrely derived from his own work. In the preface to the ixth book, he mentions that he was indebted to his paents for a good education. In the preface to the second, e speaks of himself as being small of stature, advanced in ears, and having his strength impaired by disease. From he preface to the first, we learn that he was personally nown to Julius Cæsar ; that after his death, he was reommended by Octavia to her brother Augustus ; and from his emperor he obtained a permanent provision, which laced him beyond the fear of want. The services which e rendered were those of a military engineer : " Ad apritionem balistarum, et scorpionum, reliquorumque tormentorum refectionem, fui præsto." His treatise " De Architectura," divided into ten books, is addressed to Augustus. This is a curious and valuable relique of ancient art and literature. The author was evidently a man of superior talents and learning, nor was his knowledge limited to one department : he indeed appears to have been instructed in general literature, and to have been well acquainted with the Greek writers.

The *editio princeps* of Vitruvius, superintended by Jo. Sulpicius Verulanus, is in folio, without place or date, but is supposed to have been printed at Rome about 1486. It is accompanied by the treatise of Frontinus, " De Aquæductibus," or, as it is there described, " De Aquis quæ in Urbem influunt." Both treatises were reprinted, Florent. 1496, fol. They were afterwards reprinted by Junta, Florent. 1513, 8vo. Passing various other editions of Vitruvius, we arrive at that of Guilielmus Philander, Lugd. 1552, 4to. The annotations of Philander, who is reckoned one of the principal commentators on this author, had formerly been published in a separate form, Romæ, 1544, 8vo. This edition was followed by that of Daniel Barbarus, Venet. 1567, fol. After a long interval appeared the edition of Jo. de Laet, Lugd. Bat. 1649, fol. It is splendidly printed, but is less distinguished for accuracy. With the annotations of Philander, Barbarus, and others, it contains some appendages of less importance. One of these is a Latin translation of Sir Henry Wotton's Elements of Architecture. A more suitable accompaniment is the " Lexicon Vitruvianum" of Bernardinus Baldus. We now descend to the edition of A. Rode, Berol. 1800, 2 tom. 4to. It was speedily followed by the edition of J. Glo. Schneider, Lips. 1807-8, 3 tom. 8vo. Another elaborate edition was afterwards undertaken, " textu ex recensione codicum emendato, cum exercitationibus notisque novissimis J. Poleni, et commentariis variorum, additis nunc primum studiis Simonis Stratico." Utini, 1825-9, tom. 1-3, 4to. Whether the fourth and concluding volume has made its appearance, we have not ascertained. An English translation of Vitruvius was executed by William Newton, Lond. 1771-91, 2 parts, fol. Wilkins published a translation of " The Civil Architecture of Vitruvius, comprising those books of the author which relate to the public and private Edifices of the Ancients. With an introduction, containing an historical view of the rise and progress of architecture amongst the Greeks." Lond. 1812-7, 2 vols. 4to. Of this work some copies are printed in large folio.

VITRY-LE-FRANCAIS, or Vitry-sur-Marne, an arrondissement in the department of Marne, which extends over 608½ square miles, and is divided into five cantons, and 133 communes, which in 1836 contained 50,527 inhabitants. The city stands near the junction of the rivers Orne and Marne. It is strongly fortified, tolerably well built, and had a population in 1836 of 6822. Lat. 48. 40. Long. 4. 33. east.

VIVIPAROUS, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to those that lay eggs, which are called *oviparous* animals.

VIZAGAPATAM, a considerable town and district of Hindustan, in the province of the Northern Circars. The district, principally situated between the 17th and 19th degrees of north latitude, is mountainous, and many of the hills are wild and destitute of vegetation. The principal trading towns of the district are, Vizagapatam and Bimlipatam. A considerable trade is carried on with Calcutta, Ceylon, the Maldavie islands, &c., from which are imported pepper, wheat, wine, cocoa nuts, coir, and cowries. The exports consist of wax, salt, rice, and indigo. A considerable quantity of cloth is manufactured in the adjacent country. Vizagapatam is the capital of the district. A river from the north, and turning short eastward to the sea, forms an arm of land one mile and a half in length, and 600 yards in breadth, nearly in the middle of which the town and fort are situated. The town is inconsiderable, the Europeans generally residing in Watloor, a village to the south of the harbour. At Semachellum, near to this village, is a Hindu temple of great sanctity. It was here that the British had a factory in 1689, when during a rupture with Aurenzebe, our countrymen and all their warehouses were seized, and all the residents put to death. In 1757 it was taken by M. Bussy. It was acquired by the British in 1765, with all the rest of the province, under the administration of Lord Clive; and it now forms one of the five districts into which the Northern Circars were divided in 1803, when the Bengal residence and judicial system were introduced. Travelling distance from Madras 483 miles; from Nagpoor 394; from Hydrabad 355, and from Calcutta 557 miles. Long. 83. 28. E. Lat. 17. 42. N.

VIZIADROOG, a commodious sea-port of Hindustan, province of Bejapore, situated south by east from Bombay. The mouth of the river on which it is situated is half a mile broad, without a bar: it is said to be navigable twenty-five miles for vessels of 200 tons burden; and near the mouth ships of 700 tons may anchor in safety. It possesses an excellent wet-dock 355 feet in length, and the spring-tides rise nine feet. The town is situated on a tract of table land, and is defended by a fort. It was taken by the British from the Mahrattas in 1818.

VIZIANAGUR, a town of Hindustan, in the Northern Circars, thirty-seven miles west from Gunjam. Long. 84. 45. E. Lat. 19. 21. N.

VIZIERABAD, a town of Hindustan, in the province of Lahore, situated on the eastern bank of the Chinaub or Accsines river. It belongs to the Seiks. Long. 73. 57. E. Lat. 32. 23. N.

VIZZINI, a city of the kingdom of Naples, in the island of Sicily, and province of Noto, 97 miles from Palermo. It stands on a volcanic mountain, near the source of the river Dirello, and was the Bedenum of Ptolemy. It is a very healthy spot, and contains 9100 inhabitants, and is one of the cities which sends a member to the Sicilian parliament.

VLISSINGEN, a maritime town of Holland, in the province of Zealand, called by the English Flushing. It is situated at the mouth of the West Scheldt, on the south side of the island of Walcheren, and thus in some measure commands the entrance to that river, and the access to Antwerp. In 1809 it suffered much during the siege by the British army, but has been more than restored to its former condition. The fortifications are now strong, and its trade, especially that of ship-building, is flourishing. The town contains 8020 inhabitants. It was the birth-place of the celebrated Admiral De Ruyter. Lat. 51. 26. 37. Long. 3. 28. 16. east.

VOCABULARY denotes the collection of the words of a language, with their significations, otherwise called a *dictionary*, *lexicon*, or *nomenclature*. A vocabulary is properly a smaller kind of dictionary, which does not enter so minutely into the origin and different acceptations of words.

VOCAL, something that relates to the voice or speech. Thus vocal music is that set to words, especially verses, and to be performed by the voice; in contradistinction to instrumental music, composed only for instruments, without singing.

VOCALIZE, *to*, (Ital. *vocalizzare*,) a technical term in music, signifying to sing exercises upon the vowel A only. The practice of *vocalizing* follows the study of the solfeggio in learning to sing. See Solfa, &c.

VOCATIVE, the fifth state or case of nouns. See Grammar.

VOET, GISBERT, an eminent divine, was born at Heusden on the 3d of March 1589, being the descendant of an ancient and considerable family. The earlier part of his education he received at the school of his native place, an there he astonished his teachers by his uncommon power of memory. It is said that he could repeat three entir comedies of Plautus, as many of Terence, the first book o Horace's Odes, the first book of Ovid's Metamorphoses and many other ample portions of the authors whom he ha read. In 1604 he was sent to the university of Leyden where he prosecuted his studies for seven years. Durin his theological course, he gave private lectures on logic and among his pupils he numbered the celebrated Burgersdick. Having completed his academical studies in 1611, h became a candidate for the ministry. His professiona career was retarded by a long illness; but on his recovery he was appointed to officiate in the church of Vlymen, an he preached occasionally at Engelen, about a league distant. In 1617 he accepted a call to Heusden, where h continued to officiate for seventeen years. In 1619 he assisted for six months at the famous synod of Dordrecht, an proved himself a most zealous supporter of the doctrines o Calvin. In 1634 he became one of the ministers o Utrecht; and, on the foundation of a university in tha city, he was appointed professor of divinity. He now too his doctor's degree at Groningen. During the vacation o 1637 he paid a visit to England, where he inspected th public libraries, and formed a personal acquaintance wit many learned men. For three years after his return, h discharged his duties in a very laborious manner: beside his private lectures, he gave eight public lectures a-week and likewise taught Hebrew, Syriac, and Arabic. Befor he settled at Utrecht, he was accustomed to preach eigh times a-week. He rendered himself very conspicuous b the zeal and pertinacity with which he opposed the philosophy of Des Cartes. This philosopher, who had fixed hi residence at Utrecht, was exposed to a great variety o attacks, literary and juridical, from the professor of divinity, by whom the tendency of some of his speculation was considered as highly pernicious. His public opposition commenced in 1639, and gave rise to much controversy. Voet was seconded by Rivet, Des Marets, an other divines eminent for the extent of their learning an the soundness of their theology. Having continued hi labours till a very advanced period of life, he died on th first of November 1676, in the eighty-eighth year of hi age. Among many other works, he published "Selecta Disputationes Theologicæ." Ultraj. & Amst. 1648-69 5 tom. 4to. But his principal work bears the title o "Politeia Ecclesiastica." Amst. 1663–76, 4 tom. 4to.

VOET, JOHN, the grandson of this theologian, was bor at Utrecht on the 3d of October 1647. His father, Pau Voet, who was born at Heusden on the 7th of June 1619 became successively professor of logic and metaphysics, th Greek language, and the civil law, in the university o Utrecht, and died in that city on the first of August 1677 He was likewise the author of various works. His son wa appointed professor of law at Herborn, and afterwards a Utrecht, and was finally removed to Leyden, where h died on the 11th of September 1714. We subjoin a list o his principal publications. De Jure Militari liber singular. Ultraj. 1670, 8vo. De Familia Erciscunda liber singularis. Ultraj. 1672, 8vo. Compendium Juris juxta seriem Pandectarum. Lugd. Bat. 1693, 4to. Commentarius ad Pandectas. Lugd. Bat. 1698, Hagæ Com. 1704 2 tom. fol. This last is an elaborate, and upon the whol an able work; nor has it yet lost its high forensic, as wel as academical reputation.

VOGEL, a small island in the Eastern seas. Long. 130 46. E. Lat. 5. 12. S. There is also a cluster of smal islands, under this designation, near the West coast of Siam Long. 98. 55. E. Lat. 7. 38. N.

VOGHERA, a province of the kingdom of Sardinia in the principality of Piedmont, containing two citie and 139 towns and villages, with 114,400 inhabitants. The capital is a city of the same name on the river Stoffora. It is fortified, is well built, and contains seven religious houses for monks and nuns. The inhabitants, 12,047 in number, carry on considerable trade in wine, corn, and other agricultural productions. Lat. 46. 1. Long. 8. 39. east.

VOICE, a sound produced in the throat and mouth of an animal, by peculiar organs.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form ome assemblage or little system of sounds; such are the voices expressing the letters of an alphabet, numbers of which joined together form words. Inarticulate voices are uch as are not organized, or assembled into words; such as the barking of dogs, the braying of asses, the hissing of erpents, the singing of birds, &c.

For a description of the organs of the voice, see ANATOMY and PHYSIOLOGY.

VOICE, in *Grammar*, a circumstance in verbs, by which they come to be considered as either active or passive, *i. e.* either expressing an action impressed on another subject, as *I beat;* or receiving it from another, as *I am beaten.* See GRAMMAR.

VOIGHTLAND, a province or circle of the kingdom of Saxony, which was diminished by the peace of 1814. It s bounded on the north-east by Erzgeberge, on the south-east by Bohemia, on the south-west by Bavaria, and on the north-west by Reus. The province is divided into three bailiwicks, comprehending eighteen cities or towns and 294 villages, with 102,890 inhabitants. It is 303 square miles n extent, and occupies the side or the top of a mountainous range. It is a raw and cold district and mostly a stoney soil, and on the higher parts no other corn than oats will ripen. It yields abundance of potatoes, which form the chief sustenance, much fruit, and in some portion tolerable pasture. The woods are extensive and furnish charcoal and some pitch. The chief occupation is in the muslin manufacture, which employs more than 25,000 persons. There are mines of iron and of copper, and the converting those metals into domestic articles affords considerable employment. The capital of the province is the city of Plauen on the river Elster.

VOIRON, a city of France in the department of Lozere and arrondissement of Grenoble. It stands on the river Morges, and is remarkable as the central point for the extensive trade in hempen cloth which is made in the surrounding district. There is also a fabric of sword blades highly esteemed, and there are several paper mills. The inhabitants amount to 6700.

VOLCONDA, a town and fortress of the South of India, province of the Carnatic. The port is situated on a rock 200 feet high, and a mile in circumference at the bottom. It was taken by the Mahratta chief, Sevagee, in 1677; and during the Carnatic wars of the last century, was a strong post. Long. 79. 5. E. Lat. 11. 10. N.

VOLERY, a bird-cage of such a size that the birds have room in it to fly up and down.

VOLGA, the largest river in Europe, derives its origin from two small lakes in the forest of Volkonski about 80 miles from Tver, a town in Russia. It is navigable a few miles above that town. This noble river waters some of the finest provinces in the Russian empire, and at last falls into the Caspian sea, by several mouths, below Astracan. The Volga is subject to annual inundations. In the year 1774, the inundations exceeded the lowest water mark by nearly 40 feet, since which period they have been rather on the decline; for in 1775, they rose only to 39 feet 2 inches above that mark; in 1782, they rose to 26 feet; in 1785, to 25 feet 2 inches; and in the year 1791, their height was the same. Pallas is of opinion that this phenomenon may have originated from the diminished quantity of snow and rain which had fallen in the higher countries; from the greater evaporation of the Caspian sea, and the gradual extension of the different mouths of the river, or perhaps from the joint operation of all these causes.

VOLHYNIA, or WOLHYNIA, a government, or stadholderate, of the Russian empire, extending in north latitude from 49° 28′ to 52° 3′, and in east longitude from 23° 30′ to 29° 14′. It is bounded on the north-west by Grodno, on the north by Minsh, on the east by Kieu, on the south by the Austrian kingdom of Gallicia, and on the west by the kingdom of Poland. This province belonged to Poland till the great dismemberment of that kingdom by Russia, Austria, and Prussia, when it was transferred to the first of those powers. It extends over 30,660 square miles, divided into twelve circles, and containing 139 cities and towns, and 2591 villages, with 1,394,600 inhabitants. The nobility and traders are for the most part of the Polish nation, but many of the peasants are of a Russian origin, and there are also many Jews. The major part of the population adheres to the Greek church, at whose head is a bishop of that sect. The Catholics are next in number, and mostly Poles, who have a bishop at Luzk as head of their church, and they still have many monasteries. The Jews have their own synagogues and their separate schools.

The face of the country is a high level plain, which extends northward from the Carpathian mountains. At the north there are few or no hills, but many morasses, and the elevated land between them is covered with woods of excellent timber. The southern part is undulating, and has many spurs projecting from the Carpathians, though few of them exceed 400 feet in height. Their summits are mostly covered with trees.

The soil is either a loam or clay, occasionally sandy, but generally mixed with marl, and covered with a thick coating of vegetable mould. Although in the north there are large tracts of moors and marshes, yet, by draining, they are converted into profitable meadows and corn fields. Although the process of cultivation is little better conducted than in Poland, yet there are fewer unproductive seasons, and none in which a surplus of corn is not produced. Flax, hemp, rape, and tobacco are cultivated; and some oil is made from the seed, but merely for home consumption. Hops, saffron, mustard, and capsicum are grown, but on a limited scale. The converting the forests into timber and charcoal affords considerable occupation to the labouring classes. The manufactures are solely for domestic use, and consist of linen and woollen cloth, the spinning of which is performed by hand by the females; and families buy the yarn and have weavers who go from house to execute their part of the work. Though Volhynia is nearly equal in extent to Ireland and has a better soil, yet, from want of that stimulus which access to good markets gives, it is enabled to support, and that in a wretched manner, scarcely one-fifth of the same number of human beings. The little trade that exists is in the hands of the Jews, who, by legal means, or by smuggling, send into the Austrian and Prussian territory, corn, brandy, live cattle, especially horses, and some salted meat, and also honey and bees' wax.

VOLITION, an act of willing. See METAPHYSICS.

VOLONES, slaves who, in the Punic war, voluntarily offered their services to the state, which is the reason of the appellation; upon which they were admitted to citizenship, as none but freemen could be soldiers.

VOLT, in the manege, a round or circular tread, hence, by the phrase *to make volts,* is understood a gate of two treads, made by a horse going sidewise round a centre, in such a manner that these two treads make parallel tracks; one larger, made by the fore-feet, and another smaller, made by the hind-feet; the croup approaching towards the centre, and the shoulders bearing out.

VOLTAIC ELECTRICITY.

Voltaic Electricity.

Voltaic Electricity properly designates that branch of electricity to which the name of *Galvanism* is generally applied. The term *voltaic* has been given to it in consequence of the science having been founded by M. Volta, professor of natural philosophy at Pavia, although the experiments of Galvani were prior to those of his countryman. At present we propose to comprehend under this general title, the sciences of *galvanism, electro-magnetism, magneto-electricity,* and *thermo-electricity*; and we have adopted this arrangement in order that we might avail ourselves of the various discoveries which might be made up to the close of the work.[1]

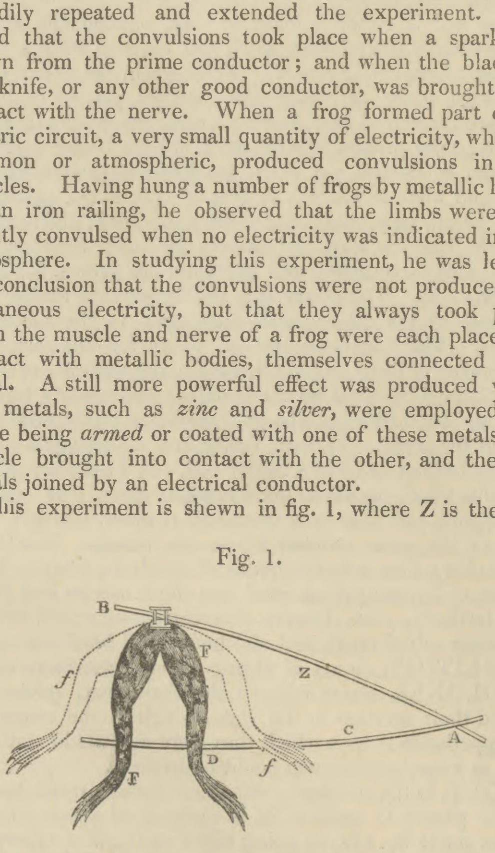
PART I.—GALVANISM.

Galvanism, A. D. 1789.

The science of *galvanism* derives its name from some interesting experiments performed in 1789 by M. Galvani, professor of anatomy at Bologna. When one of his pupils was using an electrical machine, a number of frogs were lying skinned on an adjoining table for the purposes of cookery. The machine being in action, the young man happened to touch with a scalpel the nerve of the leg of one of the frogs, when, to his great surprise, the leg was thrown into violent convulsions. Madame Galvani, having observed the fact, communicated it to her husband, who speedily repeated and extended the experiment. He found that the convulsions took place when a spark was drawn from the prime conductor; and when the blade of the knife, or any other good conductor, was brought into contact with the nerve. When a frog formed part of an electric circuit, a very small quantity of electricity, whether common or atmospheric, produced convulsions in the muscles. Having hung a number of frogs by metallic hoops on an iron railing, he observed that the limbs were frequently convulsed when no electricity was indicated in the atmosphere. In studying this experiment, he was led to the conclusion that the convulsions were not produced by extraneous electricity, but that they always took place when the muscle and nerve of a frog were each placed in contact with metallic bodies, themselves connected by a metal. A still more powerful effect was produced when two metals, such as *zinc* and *silver*, were employed, the nerve being *armed* or coated with one of these metals, the muscle brought into contact with the other, and the two metals joined by an electrical conductor.

This experiment is shewn in fig. 1, where Z is the rod of *zinc* and C the rod of *copper*. The extremity B, of the zinc is brought into contact with the *armed* muscle of the suspended limb FD, while the extremity of the copper is brought into contact with the nerve at D. When the two metals are made to touch at A, the limbs are convulsed, and take the dotted position *ff*. Galvani explained this phenomenon by saying, that the muscle of the frog was a sort of Leyden phial, the nerves representing the interior, and the muscles the exterior coating of the phial, and the discharge or shock taking place by the metal or metals, which form a communication between the two electrified coatings. The fluid which thus passed along the nerves and muscles was called the *Galvanic fluid.*

Fig. 1.



The publication of Galvani's discoveries excited great interest. The subject was prosecuted by Valli, Fowler, Robison, Volta, Wells, Humboldt, Fabbrici, and others; but the labours of Volta were the most successful, and, by his discovery of the *Voltaic pile*, he may be considered as the great founder of the science. In his earliest inquiries, Volta saw the true cause of the phenomena described by Galvani. He maintained that the exciting fluid was ordinary electricity, produced by the contact of the two metals, and that the convulsions of the frog arose from the electricity thus developed passing along its nerves and muscles. Volta afterwards proved that the force, which gave rise to these phenomena, was generated by the contact of heterogeneous bodies, that it decomposed their natural electricity at the point of junction, continually separating the two fluids, and making the *positive* electricity pass along the one and the *negative* along the other.

According to this view of the subject, every two heterogeneous bodies form a *galvanic circle* or *arc*, as it is sometimes called, in which electricity is generated; and hence Volta was led, in 1800, to invent the *Voltaic pile*, or *compound galvanic circle.*

This apparatus, shewn in figs. 2, 3, consists of a number of *single galvanic circles*, ZC, ZC, &c., each of which is composed of a disc of *zinc* and another of *copper*. These single galvanic circles are separated by a disc D, of paper, card, or cloth soaked in *water* or any other *fluid*. When thirty or forty *pair* or *couple* of zinc and copper discs, four inches square, are combined, as in fig. 2, the electricity developed will be sufficient to make the gilt leaves of an electroscope diverge, the *upper* or *zinc* end with *positive*, and the *lower* or *copper* end with *negative* electricity; and if we touch the upper end with the wetted fingers of one hand, and the lower end with the wetted fingers of the other, a distinct electrical shock will be experienced.

Fig. 2.

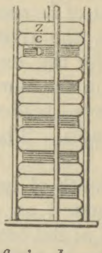


Fig. 3.

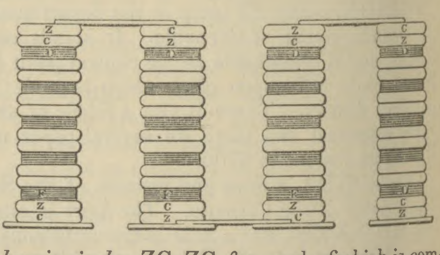
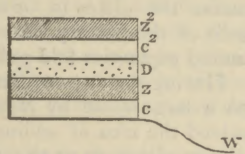


The *zinc extremity* of the pile is therefore called the *positive extremity* or *pole*, and the *copper extremity* the *negative extremity* or *pole*. The *wet* card, or disc, which separates each pair of metallic discs is called the *conductor.*

---

[1] The names *electro-magnetism* and *galvanism* occur so early in the alphabet, that the arrangement referred to could not with propriety be avoided.

Fig. 4.



In order to understand how the electricity of each lvanic pair is accumulated in the pile, let C, fig. 4, be plate of *copper*, or a *negative* ment, communicating with the ound by a wire or chain, W. hen a plate of *zinc* Z, or a *posi-* *e* element, of the same size, is ced above it, a decomposition electricity will take place at instant of contact ; the *gative* electricity will pass in- the copper and through the wire W into the ground ; ile the *positive* electricity will enter the *zinc*, and ac- mulate, till its tension, or the thickness of the electrical atum, is a maximum which we shall call 1. If we were make the zinc plate Z communicate with the ground another wire, the positive electricity with which it is arged will be carried off like the negative electricity from copper disc, and the electricity, set free by the con- t of the two metals, would be carried off as soon as it is nerated. By uniting the extremities of the two wires electricities would be recomposed, and a continual cir- lation of electricity would take place. The disc of *cop-* r C, communicating with the ground as in the figure, d the *zinc* disc Z, having an electrical intensity equal to let us place upon Z a wet disc D of card. The positive ctricity will pass from Z to D till the tension of the elec- city in D is equal to 1, a fresh supply arriving from the ntact of the two metals. The same electrical state will ntinue when a second plate of copper, C^2, is placed above e disc D. But if we place a second plate of zinc, Z^2, it ll acquire from the copper beneath it and the wet disc electrical intensity equal to 1, and from its own action the copper it will acquire another portion of electricity ual to 1, so that its electrical intensity will be 2. While is is going on, the negative electricity developed in the pper will be neutralised by the positive electricity which possesses, and in the first pair, CZ, there will be a new velopment, by which the first zinc disc Z will be brought ck to an intensity 1, as well as the disc D and the second pper C^2. Hence the second zinc disc, Z^2, can be in equi- rium only when it has an intensity double of that possess- by the first. In like manner the third zinc disc will ve an intensity 3, the fourth 4, and so on, the fortieth ving an intensity 40.

In the voltaic pile which we have now described, the *gative*, or copper pile, communicates with the earth, and e intensity of the *positive* electricity increases, at every ir, from 1 to 40. If we take another pile of similar mensions, in which the zinc or positive pile communi- tes with the earth, then the intensity of the negative ctricity will increase from 1 to 40. Let us now place ese two poles together, so that the two poles in com- unication with the ground are supported by a wet disc card, we shall have a pile of eighty pair of plates, in the iddle of which the electricity is in its natural state, its in- nsity being there 0, while at one end there will be a *posi-* e pile whose intensity is 40, and at the other end a *nega-* e pile whose intensity is also 40.

In a voltaic pile thus insulated we have electricity of op- site kinds accumulated at its two poles, and of any inten- ty we choose. If we now place a wire in contact with e pole, and another wire in contact with the other, and ing their extremities together, we shall observe an *elec-* *ic spark*. By separating them and again bringing them gether, another spark will be seen, so that there is a con- nual current of fire passing from the one extremity or le of the wire to the other.

If we now unite the two extremities of the two wires, so to close the circuit, every thing will appear to be at rest, it, notwithstanding this state of apparent repose, the electrical actions are still going on ; the electrical fluid is decomposed in each pair of plates, and again recomposed in the conducting wires. In order to prove this, we have only to interpose a piece of slender wire between the extremities or poles of the conducting wires, when it will either become hot, or red hot, or white hot, or be fused, according as it is longer or shorter, or of a greater or a less diameter. In like manner, water, acids, and other compound substances are all decomposed when placed between the poles and the wires, so as to form part of the galvanic circuit.

Voltaic Electricity.

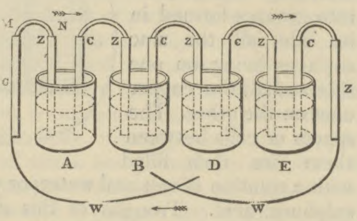
CHAP. I.—DESCRIPTION OF GALVANIC APPARATUS.

Galvanic apparatus.

In performing these experiments, and drawing from this powerful agent all the electrical energy which it is calculated to yield, a great variety of apparatus has been employed. When a voltaic pile consists of many couples, their superincumbent weight presses all the water or other fluid from the discs of card or cloth, and thus injures the action of the pile. In order to avoid this, Volta introduced the "*couronne des tasses*," which is represented in fig. 5, where A, B, D, &c., are three or more glass vessels containing acidulated water or diluted sulphuric acid; the plates Z and C of zinc and copper, about two inches square, are soldered to the ends of a bent metallic wire, M, N, &c., and are immersed in the water in the vessels. About thirty of these cups are sufficient to give a shock. When the circuit is closed, by joining the ends of the wires W, W, gas is actively evolved at all the surfaces of the plates, but when the circuit is broken the evolution of gas ceases in the copper plate, and becomes less copious in the zinc.

Couronne des tasses.

Fig. 5.

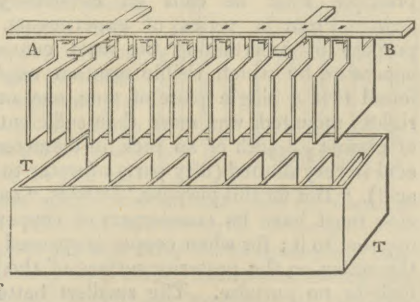


Modification of it.

A valuable modification of the "*couronne des tasses*," called the *trough battery*, was suggested by Dr Wilkinson and Dr Babington. Plates of zinc and copper, about four inches square, are joined together in pairs, by being soldered at one point. The pairs of plates are then attached to a strip of well dried and varnished wood, A B, fig. 6, so that the whole can be placed in a trough, T T, made of earthenware or wood, with as many partitions as there are pairs of plates. When the trough is of earthenware the partitions are of the same substance, but if they are made of wood the partitions are made of glass. When diluted sulphuric acid is poured into the cells of the trough T T, the battery A B, is immersed in it, so that each pair shall be separated from the adjoining one by a partition of the trough. This apparatus has the great advantage of allowing us to clean or repair the plates, without pouring out the fluid, which can also be changed with great facility. The powerful voltaic battery, constructed for the Royal Institution by Mr Eastwick, under the direction of Sir H. Davy and Mr Children, is upon this plan. It consists of 2000 double plates, and its acting surface is 128,000 square inches. When a battery consists of a number of these troughs unit-

Trough battery.

Fig. 6.



ed together, the terminal plates of the adjacent troughs are joined by slips of copper, which unite the zinc end of one trough with the copper end of the other.

Cruickshanks' galvanic trough.

The *galvanic trough*, as it is called, is shewn in fig. 7, as constructed by Mr Cruikshanks of Woolwich. Plates of zinc and copper C Z, C Z, &c., fig. 8, soldered together, are made to constitute the partitions of a trough, T T, of baked wood, by fixing them into grooves formed in its side, all the zinc surfaces being on one side and all the copper ones on the other. The spaces or cells between them are then filled with a solution of salt and water, or with diluted muriatic or sulphuric acid. Troughs of this description are very apt to get out of order from the warping of the wood by the action of the acid solution, from the cracking of the cement, and other causes which affect the condition of the cells. This trough was still farther improved by keeping the plates of zinc and copper separate as at Z, C, but united at their summits S, with a small ribbon of copper. Each of these double plates was then placed upon the earthenware or glass partitions of a trough like that in fig. 6.

Fig. 7.

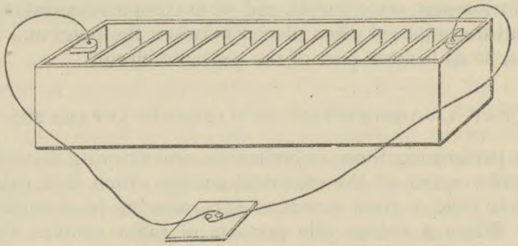


Fig. 8.

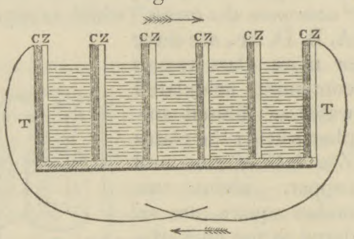

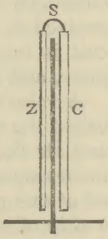

Wollaston's elementary galvanic battery.

Dr Wollaston found that the power of a galvanic battery was greatly increased, when each surface of the zinc plate was opposed to a surface of copper, and in 1815 he constructed on this principle what he calls an *elementary galvanic battery*. From a series of experiments, made for the purpose of ascertaining the most compendious form of apparatus, by which visible ignition might be shewn, he found that a single plate of zinc, *one inch* square, when rightly mounted, was more than sufficient to ignite a wire of platina $\frac{1}{3000}$dth of an inch in diameter, even when the acid is very diluted (fifty parts of water to one of sulphuric acid). " But for this purpose," he adds, " each surface of the zinc must have its counterpart of copper, or other metal, opposed to it; for when copper is opposed only to one face, the action on the posterior surface of the zinc is wasted to little or no purpose. The smallest battery that I formed of this construction consisted of a thimble without its top, flattened till its opposite sides were about $\frac{2}{10}$ths of an inch asunder. The bottom part was then nearly one inch wide, and the top about $\frac{8}{10}$ths, and as its length did not exceed $\frac{9}{10}$ths of an inch, the plate of zinc to be inserted was less than $\frac{3}{4}$ths of an inch square."[1]

Mr Children's battery.

The plan thus suggested by Dr Wollaston was employed by Mr Children in the construction of a magnificent battery, in which each plate presented a surface of thirty-two square feet; the plates being six feet long, and two feet eight inches broad. The plates are attached to a strong wooden frame, suspended by ropes and pullies, which, being counterpoised, is easily lowered and elevated, so as to immerse the plates in, or raise them out, of the acid. The cells of the battery were twenty-one in number and their united capacities 945 gallons.[2]

Having seen a new battery of Dr Wollaston's, constructed on a large scale by Newman, Mr Hart[3] of Glasgow conceived the idea of adding sides and bottoms to the double copper plates, so as to make them form cells of themselves, for holding the acidulous liquid. In this way, each galvanic pair became a *triad*, consisting of *two* plates of copper inclosing one of zinc. The following is the method of constructing such a battery as given by Mr Hart:—

" The cells are formed by cutting the copper in the form represented by fig. 9, they are then folded up as seen in fig. 10, and the seams grooved. A drop of tin is run into each lower corner, to render the cells perfectly tight, and at the same time to increase the positive state of the copper. Fig. 11. represents the zinc plate cast in the usual manner, and having a piece of screwed brass wire cast into the top of it, in order to suspend it by.

Fig. 9.

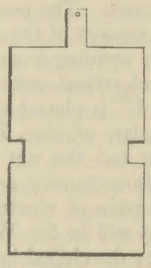

Fig. 10.

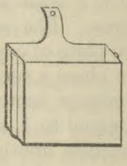

Fig. 11.

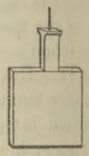

" Fig. 12. is a section of the battery, showing how the copper tail of the first cell is connected with the zinc plate of the second, and so on. This connection is rendered perfect, by joining them with a drop of solder. The zinc plates are kept firm in their place in the cells by three small pieces of wood, in the same manner as in Dr Wollaston's battery; the whol are then fixed (by means of screw nuts fitted on the bras wires) to a bar of baked wood, previously well varnished Fig. 13 represents the battery in its complete state.

Fig. 12.

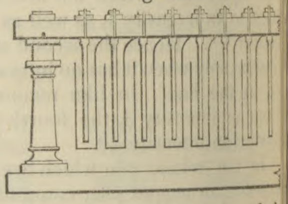

Fig. 13.

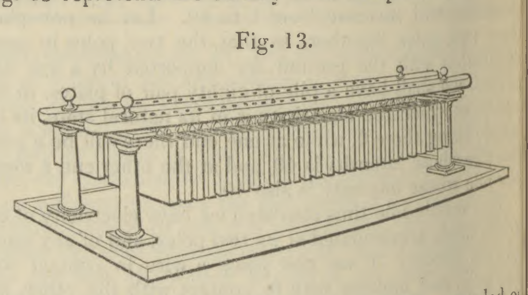

" When the battery is small, two may be suspended o one frame. When used for shocks, they may be arrange with the positive or negative poles together, and joined wit wire to complete the circuit; but when employed for de flagration, the batteries ought to be placed alongside c aic icity.

[2] Phil. Trans. 1815, p. 363.

ach other, with all the positive poles at one end, and the egative at the other, and the poles of the same name ined. This arrangement will increase the surface, while e number is the same.

art's y.

" When the battery is to be used, it is to be lifted off the ame, and dipped into a wooden trough lined with lead, to which the acid has been poured, or it may be placed the leaden trough, and the liquid poured into it, till the lls are full. It is then to be placed on the frame, and the st charged in succession."

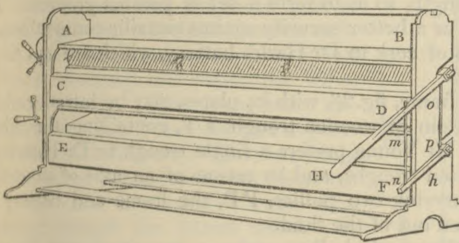
Hart's y.

Mr Candie of Glasgow constructed six batteries on this inciple, of twenty-five triads each, and they were found perior to a battery on Wollaston's construction, "with the me number of plates, but the plates of which contained uble the surface." This comparison was made in the anner proposed by M. M. Gay Lussac and Thenard. Two of Dr Wollaston's batteries, each containing ten ads in porcelain troughs, evolved a certain volume of gas *seventeen* minutes, while a battery of the new construcn, with the same number of triads, but presenting only e half the surface of the other, yielded the same volume gas in *fourteen* minutes." This effect, as Mr Hart rearks, could arise only from the superior means of insulan possessed by his battery.

are's ed , or ic ator.

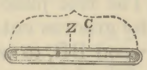
Very great improvements have been made on the galvac battery by Dr Robert Hare of Philadelphia, whose *Galnic deflagrator*, as he calls it, is represented in fig. 14,

Fig 14.



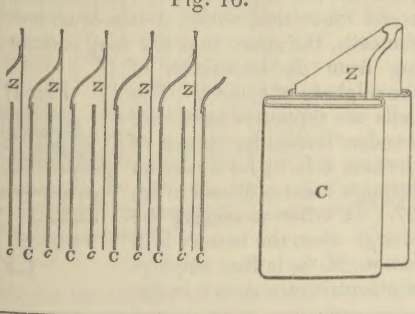
hich represents an apparatus consisting of two troughs, ch of which is ten feet long. Each trough contains 150 lvanic pairs. The galvanic series, AB, in the upper trough, shewn, as it appears when the acid is off the plates, CD ing the part of the trough containing the acid when it is the plates. In the lower trough EF, the galvanic series omitted, in order that the interior may be better underood. The series belonging to this trough is shewn in fig. . The pairs are contained in three xes, each containing fifty pairs. In plag these *three* boxes in the trough, a little ace is left between them and that side the trough in which the acid enters, so at instead of flowing over them, it may run down oute, and rise up within them.

Fig. 15.



The pairs of the series consist of copper cases, about sen inches long, three wide, and half an inch thick, each ntaining a cplate equaldistant from sides, and evented from uching it by oved stripes wood. Each c plate is solred to one e of the adjant case of copr, as shewn in fig. 16, the copper cases being open only at the top and bottom. The copper cases are separated from each other by very thin veneers of wood.

Fig. 16.



Voltaic Electricity.

Hare's galvanic deflagrator.

The two troughs, AB, EF, are joined lengthwise, edge to edge, so that when the sides of the one are *vertical*, those of the other must be *horizontal*. Hence, by turning the handle H a quarter of a revolution, the two troughs thus united upon pivots which support them at the ends, will be so raised that any fluid in the one trough must flow into the other, and by reversing the action must flow back again. In this way, the galvanic series being placed in one of the troughs, and the acid in the other, the plates may, by means of the handle H, be all simultaneously subjected to the action of the acid, or relieved from it. The pivots are made of iron, coated with brass or copper, and a metallic communication is made between the coating of the pivots and the galvanic series. The lower trough, EF, is connected with the upper one, AB, by metallic rods, *mn, op*, joining the two handles, H, *h*.[1]

Faraday's voltaic trough.

In the course of his experimental researches in electricity, Dr Faraday was led to the construction of a voltaic trough, in which the coppers, passing round both surfaces of the zincs, should not be separated from each other, except by an intervening thickness of paper, or in some other way, so as to prevent metallic contact, and should thus constitute a compact, powerful, and economical instrument. He found, however, that Dr Hare had in the trough, which we have above described, anticipated him in his contrivance. The arrangement of Dr Hare, who separated the copper plates by thin veneers of wood, and poured the acid on and off the plates, by a quarter revolution of an axis, which carries both the troughs with the plates, and another trough to collect and hold the liquid, was applied by Mr Faraday as the most convenient. His zinc plates were cut from rolled metal, and, when soldered to the copper ones, had the form shewn in fig. 17. They were then bent over a guage into the shape fig. 18, and when packed in the wooden trough, were disposed as in fig. 19, small plugs of cork being used to prevent the zinc from touching the copper plates, and a single or double thickness of cartridge paper being interposed between the contiguous surfaces of copper to prevent their contact. A trough of forty pairs of plates could thus be unpacked in five minutes, and repacked again in half an hour; and the whole series occupied only fifteen inches in length. A trough of this kind, with forty pairs of plates *three* inches square, was compared with one of forty pairs of four inch plates, having double coppers, and used in porcelain troughs, with insulating cells, and having the same strength of acid; and the former was found equal to the latter in the ignition of platina wire, in the discharge between points of charcoal, and in the strength of the shock. The following are the advantages of this form of trough enumerated by Dr Faraday:—1. It is so compact that one hundred pair of plates may go into a trough three feet long. 2. The copper bearings, on which the pivots rest, afford fixed terminations, which Dr Faraday connects with two cups of mercury fastened in front of the stand of the instrument. These fixed terminations give

Fig. 17.

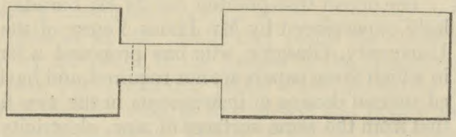


Fig. 18.

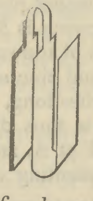

Fig. 19.

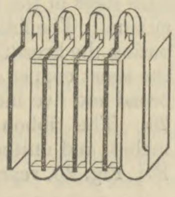

---

[1] Silliman's Journal, vol. vii p. 347, and vol. v. p 94.

Faraday's voltaic trough.

the great advantage of arranging an apparatus to be used in connection with the battery, before the latter is put in action. 3. The trough is ready for use in a few seconds, a single jug of diluted acid being sufficient to charge one hundred plates. 4. When the trough has performed a quarter of a revolution, it becomes active, and the experiment has the advantage of the *first contact* of the zinc and acid, which is *twice*, and sometimes *thrice*, that which the battery can produce a minute or two after. 5. When the experiment is finished, the liquid can be instantly poured from between the plates, and hence the latter is never needlessly wasted, the acid unnecessarily exhausted, or the zinc uselessly consumed. The charge, too, is mixed and made uniform, and the advantage of a *first contact* is obtained in the next experiment. 6. The saving of zinc is so very great, that Dr Faraday estimates the zinc to be *thrice* as effective as that in the ordinary form of battery. 7. The surfaces of the zinc and copper plates may be brought much nearer to each other when the battery is constructed, and remain so till it is worn out. 8. Thinner plates of zinc will do the duty of thicker ones, and rolled zinc, which is the purest,[1] may be used. 9. The purity of the diluted acid is proportioned to the quantity of zinc dissolved. 10. The acid is more easily exhausted, so that we need not use an old charge a second time. 11. By using a due mixture of nitric and sulphuric acid for the charge, no gas is evolved from the troughs. Among the defects of this form of the battery, Dr Faraday enumerates the precipitation of copper on the zinc plates, which he considers as arising chiefly from the papers between the coppers retaining acid when the trough is emptied, which acid, acting slowly on the copper, forms a salt, which gradually mingles with the next charge, and is reduced on the zinc plate by the local action, and hence the power of the whole battery is reduced. Dr Faraday proposed to remedy this evil, by using slips of glass to separate the coppers at their edges.[2]

Mr Young's improved battery.

The defect thus pointed out by Mr Faraday, was particularly experienced by Mr James Young of the Andersonian University, Glasgow, who has proposed a form of battery in which these papers are not required, and having constructed several dozens of instruments in the new form, he found that from the same surfaces of zinc, electricity, the same in quantity and tension, is produced in both Dr Hare's form and his, but that in the new construction, this effect is produced with *half* the quantity of sheet copper, which arises from both sides of the copper plates being presented to surfaces of zinc. The following is Mr Young's construction. Supposing the breadth of the required plates to be two inches, the sheet copper and zinc are cut into ribbands, two inches broad and five inches long, and a portion cut out as in fig. 20. The ribbon is thus divided into two squares of two inches, and united at A, and having a piece projecting at B. Fig. 20, representing a single plate, either of zinc or copper, is bent at A, as in fig. 21. A plate of zinc thus bent, is then united to a similar one of copper, by soldering together the projecting parts BB, as in fig. 22, and this is the only metallic communication existing between them. Each pair of plates is constructed as in fig. 22. In arranging a number of pairs to form a battery, they are interlaced so that a copper square comes in between each couple of zinc squares, and *vice versa*. This arrangement is not easily described. At the positive end of the battery there is a single copper plate, which is soldered at the top to the last double copper plate, as seen in fig. 23, which represents three pairs properly arranged, and also the way in which they should be fitted up, and kept steadily apart in a wooden frame. This frame is made of two solid pieces of wood, into which are dove-tailed two cross bars, *ee*, *e′e′*, in front, with two similar ones behind. The grooves in the cross bars for receiving the edges of the plates, are formed by placing the four cross bars together, and sawing a little way into one side of them all every eighth of an inch or so in their length, so as to form a set of parallel grooves. This affords us a better security against metallic contact than the wedges of cork in Dr Hare's battery, which are apt to slip out.

Fig. 20.

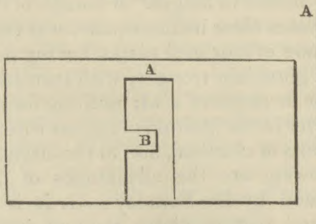

Fig. 21.

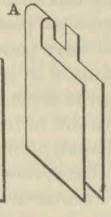

Fig. 22.

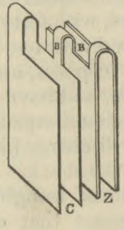

Fig. 23.

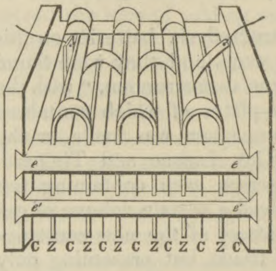

Fig. 24.

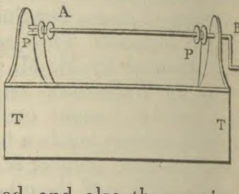

Young's
ery.

The frame, fig. 23, with its plates, may be introduced into a porcelain or wooden trough, T T, containing the diluted acid. Mr Young prefers a single trough to Dr Hare's two connected troughs, and by means of an axis of stout wire, A B, carrying two pullies, P P, the frame and battery can be raised out of the fluid.

la Rue's
ttery.

Mr Warren de la Rue made an important step, by using a solution of sulphate of copper as the exciting agent in voltaic batteries. Oxygen is thus supplied to the zinc by the oxide o copper; no gas is evolved; and the action being thus rendered continuous, the effect is fully equal to that momentarily produced by immersion in acids. The battery which M. de la Rue considers best adapted to the use of sulphate of copper, is shown in fig. 28. The zinc plate is shown in fig. 25. It should be tinned on the top A, previous to the amalgamation of the rest of the plate. The zinc plate is retained in its place by grooves cut out of the two slips of wood BB, to within 3-4ths of an inch of the bottom. The copper plates are formed into cells, painted on the outside (as in fig. 26,) five inches square and one inch wide E, E, being two ears of copper for suspending the cell in it place, and A, a slip of copper to be soldered to the zinc plate in the adjacent cell. As the zinc plates do not descend lower than within 3-4ths of an inch of the bottom o the cells, the space thus left may contain the deposits arising from decomposition of the sulphate of copper. The cells are supported in a long wooden frame, by means of the ears E, E, by hooks driven through them as shown in fig. 27. In order to receive the charge when the battery is in action, M. de la Rue employs the contrivance shown in fig.

---

[1] Dr Faraday found rolled Liege or Mosselman's zinc the purest.

[2] Phil. Trans. 1835, Part ii.

8. A spout L, a quarter of an inch deep, is placed at the op of each cell, and these spouts overhang a wooden gut-er extending along the frame. The solution of the sulphate ust then be renewed by means of a funnel with a long eck, the long end being made to descend nearly to the bot-om of the cell. When the fresh solution is thus poured in, e spent liquor will run out by the spout into the gutter. Vhen a series of experiments is over, the battery must be mptied, and the plates well cleaned by dashing water be-ween the cells.[1] Mr Noad justly recommends this battery s a very valuable one, and as likely to supersede the *acid harged* battery altogether. Its initial action was equal to ne of Wollaston's batteries of equal surface, and what is f far more importance, its action was permanent.

Professor Daniell has published in the Philosophical Trans-ctions for 1836, an account of two new voltaic batteries, ossessing valuable properties. The first of these he calls e *dissected battery*, by means of which he says, "many etached facts well-known before, had become clear, and of ore importance, from their connection and comparison ith each other by its means." The following is Mr Daniell's wn description of it:—The battery consists of ten glass ells, a section of one of which is represented in the accom-anying figures.

"*a b c d*, fig. 29, is a foot of solid glass, containing a avity *e f g h*, the upper part of which s fitted with a stopper, *g h*. Through his stopper the stems of the two plates *j k l m n*, pass into the lower part of he cavity, which is divided into two cells y the partition *o p*, and each of which ontains mercury, into which the wires espectively dip. This arrangement ad-its of the plates being changed at plea-ure with little difficulty. The plates may e connected together, or with the plates f other cells, by means of wires, *p q*, assing through the lateral holes, *t*, *u*, nd dipping also into the cups of mercury. To the glass foot thus arranged, a glass hade *v w x y z z*, is fitted by grinding, nd constitutes a cell for the reception of he liquid. A graduated glass jar, A, B, ay be suspended over either plate by eans of a brass clip, proceeding from a od placed by the side of the cell in the anner represented by fig. 30, which is a perspective rawing of a circular arrangement of ten such cells.

Fig. 29.

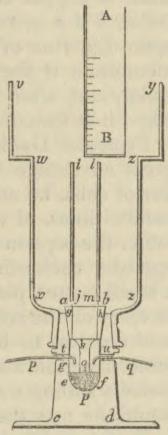

Fig. 30.

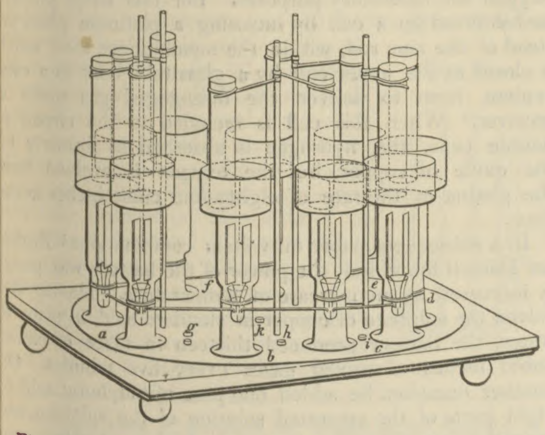

Fig. 31 represents the section of a cell which is adapted to the same purposes, but is less expensive in construction. It is supported in a perforated table C, D, by its projecting rim *v w y z*, and the stems of the plates pass through the glass stopper *a b c d*, into the exterior mercury cups *o*, *p*, by means of which all the necessary connexions may be made.

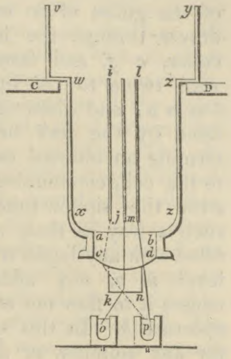
Fig. 31.



The circular arrangement of the cells of the battery, fig. 30, admits of their being combined together in various ways with the greatest facility, by means of small cups of mercury *g*, *h*, *i*, placed at proper intervals. My next disposition was to connect all the platinum plates together by wires radiating from them to a central cup *k*, of mercury, and all the zinc plates by wires, dipping into a ring of the same metal, placed in a groove *a b c d e f*, surrounding the whole arrangement. In this state of things no action was of course manifest, for there was no complete circuit; but upon making a connection by means of a wire, between the central cup and the exterior circle of mercury, the current was enabled to circulate, and was manifested by the simultaneous evolution of gas from all the cells. The inequality of action became again apparent, and the differences between the cells was nearly the same, as when they were connected in separate single circuits."

Notwithstanding the numerous improvements which have been made in the voltaic battery, no successful attempts had been made till the time of Professor Daniell, to discover the causes of the variations and decline of its force, after the first immersion of the plates in the diluted acid. The principal causes of these variations he proved to be the evolution of hydrogen gas from the negative metallic surface, which not only consumes a considerable portion of the generated electricity, but reduces at the conducting plates the oxide of zinc, formed by the action of the battery at the generating plates, and here the conducting plates were ultimately so encrusted with metallic zinc, as to diminish and finally annihilate the circulating force. Hence he was led to the construction of what he calls a *constant battery*, for producing an invariable current of force, and therefore applicable to many important researches, which cannot be successfully carried on under variation of the voltaic current. But beside the attainment of this great object, Professor Daniell considers it as promising the following advantages:

Professor Daniell's constant battery.

1. The abolition of all local action, by the facility of applying amalgamated zinc.
2. The trifling expense of replacing the zinc rods when worn out, and the total absence of any wear of the copper.
3. The dispensing with the use of nitric acid, and the substitution of the cheaper materials, sulphate of copper and oil of vitriol, and the absence of any annoying fumes; and,
4. The facility and perfection with which all metallic communications may be made, and different combinations of the plates arranged.

The following is Professor Daniell's description of this valuable instrument.

Fig. 32 represents a section of one of the cells, ten of which are shown in connexion at fig. 53; *a b c d* is a cylinder of copper six inches high and three and a half inches wide; it is open at the top *a b*, but closed at the bottom, except a collar, *e f*, one and a half inch wide, intended for the reception of a cork into which a glass siphon-tube, *g h i j k*, is fitted. On the top, *a b*, a copper collar, corresponding with the one at the bottom, rests by two hori-

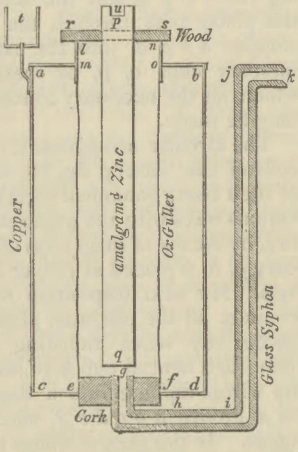
---

[1] London and Edinburgh Philosophical Magazine, April 1837, vol. x., p. 244.

Professor Daniell's constant battery.

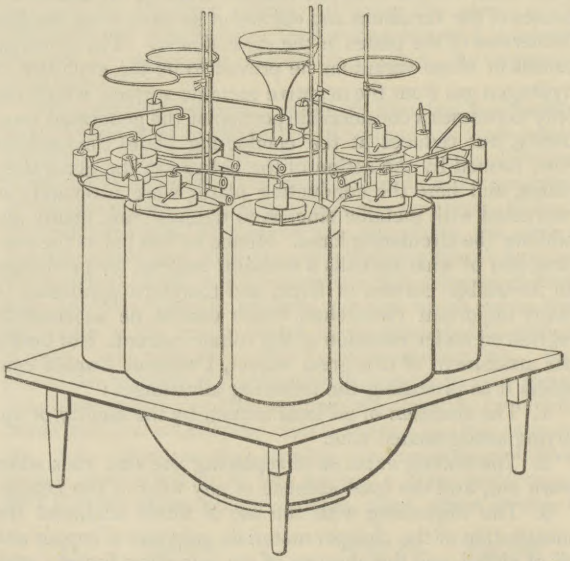
zontal arms. Previously to the fixing of the cork siphon-tube in its place, a membranous tube, formed of a part of the gullet of an ox, is drawn through the lower collar, *e f*, and fastened with twine to the upper, *l m n o*; and when tightly fixed by the cork below, forming an internal cavity to the cell, communicating with the siphon-tube in such a way as that, when filled with any liquid to the level *m o*, any addition causes it to flow out at the aperture *k*. In this state, for any number of drops allowed to fall into the top of the cavity, an equal number are discharged from the bottom. *p q*, is a rod of cast zinc, amalgamated with mercury, six inches long and half an inch diameter, supported on the rim of the upper collar by a stick of wood, *r*, *s*, passing through a hole drilled in its upper extremity; *t* is a small cup for the reception of mercury, by which, and the cavity *a*, at the top of the zinc rod, various connexions of the copper and zinc, of the different cells, may be made by means of wires proceeding from one to the other.

Fig. 32.



In fig. 33 the ten cells are represented as connected in single series, the zinc of one with the copper of the next. They stand upon a small table in a circle, with the apertures of the siphon-tubes turned inwards, surrounding a large funnel, communicating with the basin underneath, for the reception of any liquid which may overflow. A smaller funnel is supported over the internal cavity of each cell by a ring sliding upon rods of brass placed between each pair of cells. One of these only is shown in the drawing to avoid the crowding of the sketch."

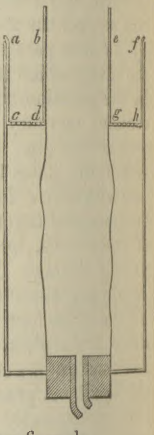
Fig. 33.



In the preceding construction, Mr Daniell had two main objects in view. 1. To remove out of the circuit the oxide of zinc as soon as its solution is formed; and, 2. To absorb the hydrogen evolved upon the copper without precipitating any substance injurious to the latter. The *first* of these objects is completely effected by suspending the rod in the membranous cell, into which fresh acidulated water is allowed to drop slowly from the funnel above, whilst the heavier solution of the oxide is withdrawn from the bottom at an equal rate by the siphon-tube, *g h i j k*. The *second* object was attained by charging the space round the membrane with a saturated solution of sulphate of copper instead of dilute acid. When the circuit was completed the current passed freely through this solution, no hydrogen appeared upon the conducting plate, but a beautiful thick coating of pure copper was precipitated upon it, thus perpetually renewing its surface.

Notwithstanding these charges, there was still a gradual, though very slow, decline in the force of the battery, which Mr Daniell traced to the weakening of the saline solution by the precipitation of the copper, and consequent decline of its conducting power. In order to remedy this defect, he suspended some solid sulphate of copper in small muslin bags, which just dipped below the surface of the solution in the cylinder, and kept it in a state of saturation by its gradual dissolution. With this improvement the voltaic current became perfectly steady for *six* hours together. An improvement upon this arrangement is shewn in fig. 34, where *a c f h*, is a perforated colander of copper, into which, instead of muslin bags, the sulphate of copper is placed. The central collar, *b d e g*, rests by a small ledge upon the rim of the cylinder. The membrane is then drawn through the collar, and, after being turned over its edge, it is fastened with twine.

Fig. 34.



Professor Daniell having found it of great advantage to increase the number of cells, he now places them in two parallel lines, of ten each, upon a long table, the siphon-tubes being disposed opposite each other, and hanging over a small gutter, placed between the rows to carry off the refuse solution when the acid requires to be changed; and as a uniform action may be kept up by occasionally adding a small quantity of fresh liquid, he now dispenses with the dripping funnels.

Professor Daniell considers a battery of twenty cells as amply sufficient for all the purposes of demonstration and investigation. It keeps eight inches of platinum wire, $\frac{1}{100}$th of an inch in diameter, permanently red hot in the open air, and it is even an economical source of the purest oxygen for laboratory purposes. For this latter purpose he has fitted up a cell by inclosing a platinum plate, instead of the zinc rod, within the membranous tube, which is closed at the upper end by a glass tube bent in a convenient form to deliver the disengaged gas under a receiver. When this cell is included in the circuit of double cells, the hydrogen is absorbed as formerly by the oxide of copper, but the oxygen is evolved from the platina at the rate of eighty-four cubic inches in the hour.

In a subsequent paper on voltaic combinations[1] Professor Daniell found that the power of the battery was greatly increased by an increase of temperature. Having dissolved the sulphate of copper in standard acid, in place of water, the battery produced thirteen in place of eleven cubic inches of mixed gases every five minutes. On another occasion, he added one part of sulphuric acid to eight parts of the saturated solution of the sulphate, and poured it into the cells, when of the high temperature pro-ıced by the disengagement of heat during the mixture, ıich was about 110°. The battery afforded at first enty-two inches of the mixed gases in five minutes.

---

[1] Phil. Trans. vol. xxxvii. p. 119, &c

Wishing now to try the effect of higher temperatures, he placed the membranous tubes with cylinders of porous rthenware. These cylinders, closed at the lower ends, ıd their diameter one and a half inches, and the same ight as the copper cells. The bottoms of the latter are ted with sockets in which the tubes are placed, and hich confine them in their proper position, the perforated colanders, which hold the sulphate of copper, passg over their upper ends. These porous tubes require to thoroughly soaked in dilute acid. The increase of mperature was obtained from steam, and the general reılt of many experiments was, *that the working rate of is battery was nearly doubled at a temperature of* 212°, rovided no secondary action interfered with it.[1]

sor ll's ved nt y.

In the interesting paper which contains these observaons, Professor Daniell has described an improved *constant* attery of large dimensions, the effects of which exceeded s most sanguine expectation, and which he thinks cannot farther improved in point of simplicity and cheapness. his battery consists of *ten* copper cells, twenty inches igh, and three and a half inches diameter. The interior artitions are formed by merely tying the open ends of the xen's gullets to the rings of the colanders which hold the lue vitriol, and which are made deeper than before, and ıspending them in the cells, to the bottoms of which they ach. Each bag contains rather more than a quart of the ilute acid. The zinc rods are five-8ths of an inch in diaıeter, and well amalgamated, and their connexions the ame as formerly. At the temperature of 67° this battery roduces, in the voltameter, twelve cubic inches of the ixed gases per minute, or 720 in the hour. It has great ower of ignition, and while it will maintain six inches of latinum wire, $\frac{1}{100}$ of an inch in diameter, red hot, it will ill decompose water at the rate of fourteen cubic inches *five* minutes. When the battery is not in use, the zinc ds are taken out and wiped, and the membranous bags refully lifted out of their cells, emptied of their acid, filld with water, and suspended from a frame placed for their ception. Professor Daniell adds, that there is no reason think that the limits of efficiency have yet been nearly ttained, and the gullets could easily be connected together as to obtain bags of any required length. Professor aniell has more recently put in action seventy series of is large constant battery, which, on the 16th February 839, fused titanium, and heated sixteen feet four inches of o. 20 platinum wire.

Iul- quan- attery

Another form of the constant battery we owe to J. W. Iullins, Esq., M.P., who calls it the *quantity battery.* It onsists of an earthenware pot six inches deep and four ide, which is shewn in action in fig. 35, nd in perspective in fig. 36, a cylinder f amalgamated zinc, Z, Z, standing on gs half an inch long, and cut out of ıe cylinder, is placed in the pot; the eight of the cylinder, including the legs, only two inches. Within this cylinder, nd at the distance of three-8ths of an ıch from it, is placed a copper vessel c, having round its outer edge a rim quarter of an inch wide, round which a hin bladder, well cleaned and moistened, tied. The bottom of the pot rests on a ircular piece of baked wood projecting a quarter of an inch beyond the cylinder. The bladder is then drawn all over and fastened round the upper rim by a cord, and it is kept clear of the copper by the circular piece of wood. The copper cylinder *c c*, which is as deep as the pot, is perforated with six holes equidistant from the top and bottom. These holes form communications with an inner cylinder of copper C, C, three quarters of an inch distant from the outer one. The shelf bottom of the space between the two cylinders, is on a level with the lower edge of the holes, and soldered to the large cylinder. The object of this cylindrical chamber is to hold crystals of sulphate of copper when required, and to contain the solution, which should not rise higher than the upper edge of the holes. A small quantity of sal-ammoniac, (muriate of ammonia,) in the proportion of five parts of the saturated solution to 100 of water, is then poured outside the bladder till it reaches the upper edge of the zinc cylinder Z Z. The solution of sulphate of copper will require a few crystals of the sulphate to be added every four hours, but the ammoniacal solution needs no renewal. The connexions are formed, as in fig. 36, by strips of copper soldered to the zinc cylinder Z Z, and to the inner copper cylinder C C. The wires bend over the edge of the pot and enter two cups holding mercury, from which the wires that transmit the electrical current through any apparatus, may proceed. The action of this battery will continue as long as a particle of metallic salt remains in solution. If *six* drops of a saturated solution of the sulphate of copper are added to the exhausted and colourless solution, the battery instantly resumes its original power. A constant current, therefore, may be kept up by having a few crystals of the blue vitriol on the shelf, which, by being gradually dissolved, will pass to the external surface of the copper.

Fig. 35.

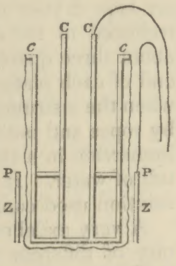


Fig. 36.

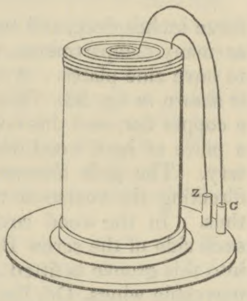

Mullins' intensity battery.

Mr Mullins has constructed also a battery for intensity, of the effects of which he has given the following description:[2]—"I have put," he says, "as in the quantity battery, a shallow cylinder of zinc within, and close to the internal surface of the earthenware pot, next the copper cylinder, as before; but, instead of letting the inside of this cylinder go for nothing, the internal surface of the copper is lined with very thin caoutchouc for insulation; then comes another small cylinder of zinc, then a copper one lined as the last, then a zinc, and lastly, a copper cock, copper, of course, enveloped in membrane. In this battery the power is immense in proportion to the quantity of the metals used, which, in my opinion, depends upon a new principle, which is developed in this mode of construction and arrangement, that is, *restricting* the electric current to gradually *diminishing metallic surfaces* as it advances, so that, as the quantity accumulates, the conducting surfaces are *reduced,* and of course a much higher degree of intensity is a necessary consequence. By merely altering the connexions of the plates, which, by the mode I have adopted, can be done with the utmost facility, this battery can be turned into a powerful quantity one, and probably a wine glass full of the solution is amply sufficient."

Rev. Mr Shillibear's sustaining battery.

Having found that a single piece of zinc, of three square inches, surrounded by a membrane, could be easily fitted up, Mr Shillibear constructed the galvanic apparatus shown

---

[1] The experiments of Marianini and Rogers on the influence of heat upon single voltaic circuits will be found in the *Annales de Chimie,* om. xxxiii. p. 132, and Sillimans' *Journal,* vol. xxvii. p. 57, January 1835. In Roger's experiments the deflection of the galvanometer, ose from 70° to 147° while the temperature rose from 75° to 210°.

[2] Lond. and Edin. Phil. Mag. 1836, vol. ix. p. 283.

Rev. Mr Shillibear's sustaining battery.

in figs. 37 and 38. It consists of a copper trough, C C, three inches deep, and two and a quarter wide, divided into as many compartments, with copper partitions, as we wish to have zinc plates. A section of a trough, for *five* plates, is shewn in fig. 38. The zinc plates are soldered firmly to a copper bar, and this copper bar is fastened by a screw to a piece of hard wood which serves as a cover to the battery. The *pole director*, shewn at the top of fig. 37, for directing the course of the electric current, is constructed thus. In the wood cover, C C, there is cut a groove on each side of the screw B, in connexion with the zinc, and into this groove is fitted a copper slide, which carries two moveable wings, D*d*, E*e*, which may be easily brought into contact with the copper or zinc. When the wing D*d* is in contact with C, and E*e* with B, the current of electricity will go out from the wire in connection with the wing D*d*, and return by the wire connected with the wing E*e*, into the zinc plates through B. If we now shift the slide, so that E*e* is in contact with C, and D*d* with B, the current will be reversed, going out by the wire at E*e*, and returning by the wire at D*d*, to the zinc through B. In order to prevent any precipitation of the sulphate of copper upon them, the zinc plates should be lightly covered with bladder. When the trough is to be employed for sustaining a weight, the membranes should be slipped off, and diluted nitrous acid used instead of the sulphate of copper solution.

Fig. 37.

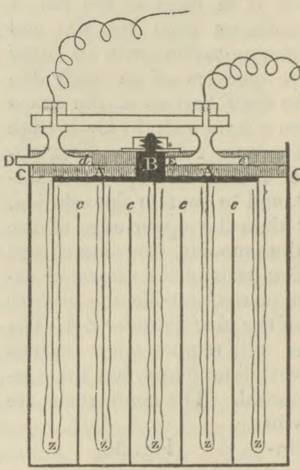

Fig. 38.

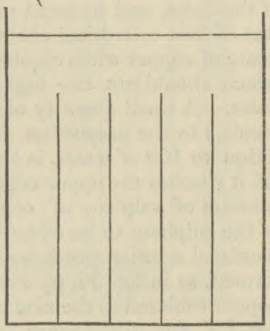


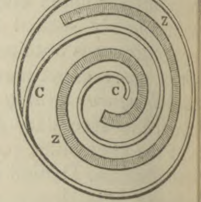
Bachhoffner's battery.

A galvanic battery of a very simple kind, and easily constructed, has been employed by M. Bachhoffner.[2] A piece of thin sheet copper, coiled up in the form of a cylinder, 4 inches by 2½, is kept in that state by a fine copper wire. The cylinder is then placed in a small bladder tied round the copper with pack-thread. The bladder is open at top, and its bottom forms the bottom of the cylinder. A sheet of rolled zinc is coiled up in a similar manner, and a piece of copper wire, previously soldered to each zinc and copper cylinder, forms the connexion between them. This battery may then be placed in a jelly-pot. It is excited by a saturated solution of sulphate of copper, poured into the copper cylinder. Another solution of common salt is poured in on the outside of the copper, and in contact with the zinc. If it be required to keep the battery in action for two or three days, a few crystals of sulphate of copper must be added, to keep up the strength of the solution within the copper cylinder.

Dr Hare's calorimotor.

Before concluding this part of the subject, we must notice the spiral galvanic batteries. The first battery of this kind on a large scale, was made by Dr Robert Hare, who called it a *calorimotor* from its remarkable power of producing heat. It consists of sheets of zinc and copper formed into coils, the copper coil encircling the zinc at a distance not exceeding a quarter of an inch. The sheets of zinc were about 9 inches by 6, and the copper 14 by 6, more of the copper being necessary as shown in fig. 39, where ZZ represents the zinc, and C C the copper coil. Each coil was about 2½ inches in diameter, and they were 80 in number. All these coils were let down by means of a lever, into 80 glass jars, 2¾ diameter, and 8 inches large, containing the acid solution for exciting them.[3]

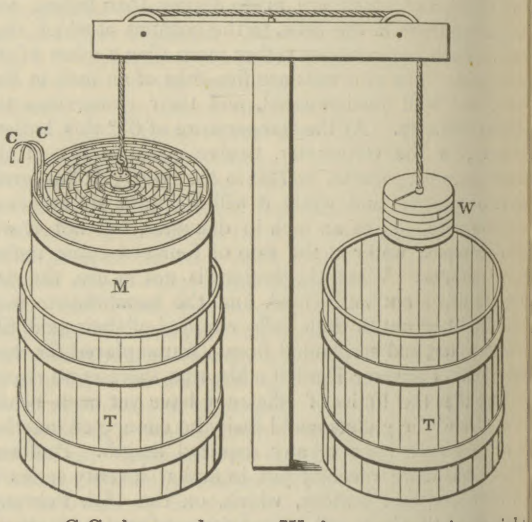
Fig. 39.



M. Pouillet constructed one of these with twelve couples for the Faculty of Sciences at Paris, and found it very powerful in producing great quantities of electricity with low tension.

Mr Pepys constructed a similar instrument on a grand scale, for the London Institution, in 1822, for electro-magnetic purposes. It is represented in fig. 40, where M is the battery, C C the conductors, W the counterpoise weight and T T the tubs, one for holding the dilute acid, and th other water. The battery M, consists of two plates of cop per and zinc each *fifty* feet long, and *two* wide, exposing superficial surface of 400 feet. They are rolled or wrappe round a cylinder of wood, with three ropes of horse hair be tween each fold to keep them from contact, and these rope are kept in their position by notched sticks, occasionally in troduced in the rolling. Two conductors C C, of coppe about three quarters of an inch thick, are soldered to th end of each plate, from which the electric force is obtaine when the instrument is in action. The battery is suspende by ropes and pullies, with a counterpoise W, to permit it immersion in a tub of diluted acid, or when not in use in tub of water. It requires about 55 gallons of fluid, and th solution used contains about $\frac{1}{40}$th of strong nitrous acid.[4]

Fig. 40.



A very excellent galvanic battery for producing electri city of different intensities, has been described in 1835 by Mr Joseph Henry, of New Jersey college.[5] The objec of the apparatus is to exhibit most of the phenomena o galvanism, and of all those of electro-magnetism on a larg

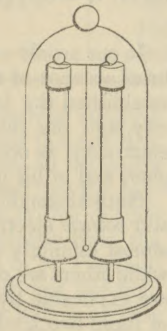
le, with one battery. It consists of 88 pairs, each of ich is composed of a plate of rolled zinc, 9 inches wide d 12 long, inserted in copper cases, open at top and bottn. These elements are suspended in groups of 11 pairs, 8 sets in all; and each of the 8 troughs which are raised to the elements, are divided into 11 cells by wooden rtitions coated with cement.

and ties elec- dry

An electric apparatus, in which the phenomena were supsed to be independent of chemical action, was invented J. A. de Luc, in 1809. It consists of a great number alternations of small discs of zinc, and silvered paper, out an inch in diameter. These discs succeed each ier in the following order: zinc, silver, paper; zinc, silr, paper. When from 500 to 1000 discs are enclosed in lry glass tube, and the plates are pressed together by a ss cap and screw at each end, the pile will produce disct electrical effects. When the columns of 1000 series ch, are fitted up as in fig. 41, and placed rtically in a glass receiver, a brass ball, pended by a thread of raw silk, will, the action of the two piles, continually ke the two bells placed at the lower l of the piles. Mr B. M. Forster sucded in making an apparatus analogous the preceding, which rung continually five months. Mr Singer made one, ich rung continually for 14 months, l De Luc had a pendulum which kept rating for more than two years.

Fig. 41.



Mr Singer found that when the paper s perfectly dry, the pile lost all its power, l that it was deteriorated when too much isture was present. M. Jaeger, however, erved, that when the paper, after being dried to excess, was ted by exposing the pile to a temperature of from 104° 140°, the pile began to act as powerfully as before. ien the paper is in its driest natural state, the pile is ace, and it loses its activity only when the paper is subted to a degree of heat capable of scorching it. By means a pile of 20,000 groups of silver, zinc, and double discs writing paper, a series of distinct sparks were obtained. ar, having a coated disc of 50 square inches, was charged 10 minutes, and gave a disagreeable shock in the elbows l shoulders. The charge of this jar fused one inch of tina wire, the five-thousandth of an inch in diameter. is pile, though exhibiting such power, did not exercise slightest chemical action.

The two ends of the electric pile are in opposite electric es, the *zinc* extremity being *positive*, and the *silver* exnity *negative*, the middle part being in a neutral state.

M. de Luc and M. Hausman observed that the rays of the increased the power of the column, an effect which they ught was not due to heat. Mr Singer, however, found t his column was always more powerful in summer than in ter, and in a room with a fire than in one without it.

M. De Luc has shown how the dry pile may be used in ermining the conducting power of bodies, and also their ulating qualities, and he has likewise employed it as an ial electroscope for indicating the electrical changes which e place in the atmosphere.[1]

ni's e.

In 1812, Professor Zamboni of Verona made a considere improvement on the pile of De Luc. He dispenses enly with the discs of zinc, and employs only discs of paper, of whose surfaces is silvered, or rather *tinned*, and the er covered with a thin film of the peroxide of manganese verised in a mixture of milk and flour. The faces of are placed in contact with those of manganese, the *tin* being the *positive*, and the *peroxide* the negative element. M. Zamboni has been endeavouring during the last 20 years, to produce by this pile a *perpetual* or long-continued motion; but the motion, though often long-continued, frequently ceases for a while, and sometimes altogether, when the electric force of the apparatus has been enfeebled.

M. Gassiot obtains chemical decomposition by the pile.

Chemists and natural philosophers had in vain endeavoured to produce chemical effects by means of the dry pile; but M. Gassiot has very recently[2] succeeded in exhibiting its chemical power. Having constructed a pile of 10,000 series of discs of laminated zinc, paper, and oxide of manganese, each about one inch in diameter, he divided it into separate piles of 1000 each. With this apparatus he succeeded in obtaining sparks which passed through the space of $\frac{1}{10}$th of an inch. When the distance of the points was $\frac{1}{30}$th of an inch, the stream of sparks was so powerful as to produce that peculiar phosphorescent odour which is always perceptible in the action of the electrical machine. With one of the piles of 1000 series, a spark passed through a space of the $\frac{12}{2000}$dth of an inch; but what was of more interest, M. Gassiot succeeded, after many trials, in obtaining chemical decomposition of a solution of *iodide* of *potassium*. He fastened about two inches of platinum wire to each end of the pile of 10,000 series, the two points of his micrometer electrometer being brought parallel to each other, so as to be about a quarter of an inch apart. A piece of bibulous paper saturated with a solution of iodide of potassium was placed on a slip of glass, and then brought into contact with the ends of the wires from each extremity of the pile. The iodine then appeared invariably on the end of the wire attached to the end of the pile, which terminated with the oxide of manganese.

Bohnenberg's electroscope.

The dry pile has been applied with much success by M. Bohnenberg, in constructing an electroscope of great delicacy. Having suspended between the two opposite poles of two piles a single strip of gold leaf, he found that this leaf, however slightly it was electrified, was drawn to one or other of the poles, according to the nature of the electricity with which it was influenced. In this way he obtained an instrument, not only sensible to small electrical influences, but capable of indicating the kind of electricity which was present.[3]

Before concluding this part of the subject, we shall describe some series of apparatus, which have been employed in the most recent researches, both in this country and on the continent, in conducting the important researches to which we shall afterwards refer, respecting the reduction of oxides and earths by *weak electric* currents.

M. Becquerel's decomposing cell.

M. Becquerel employed only a single pair of plates, in connection with his decomposing cell. Having closed a glass tube at one end by a plug of moistened clay, he immersed it in a weak solution of common salt. The solution of the metallic salt to be decomposed, was then placed in this glass tube, and a compound metallic arc, formed of zinc and platinum, was placed in the solution in such a manner, that the platinum leg was immersed in the tube containing the metallic solution (the *negative tube* of Becquerel), while the zinc dips in the solution of salt. Chemical decomposition then takes place, and in a few hours or more, sometimes a few weeks, the metal appears on the plate of platinum, in a form more or less crystallised.

Dr Bird's decomposing battery.

Dr Golding Bird, in prosecuting similar researches, has contrived a simple form of the battery, which with Becquerel's cell, enables us to perform this class of experiments with facility and certainty. It consists of a large glass cylinder A, (fig. 42,) 8 inches deep and 2 in diameter. With-

Dr Bird's decomposing battery.

in this is fixed, by means of corks, another glass cylinder B, 1½ inch in diameter, and 4 inches long, and closed at one end with a plug or bottom, D of plaster of Paris, 0·7 of an inch in diameter. A piece of sheet copper C, 6 inches long, and 3 wide, loosely coiled up, and having the conducting copper wire F, soldered to it, is placed in the cylinder D, while an equal sized piece of zinc E, loosely coiled up, and furnished with a conducting wire G, is placed in the cylinder A. When the cylinder A is nearly filled with weak brine, and the smaller one B, with a saturated solution of sulphate of copper, the apparatus is complete; and if the fluids in the two cylinders are kept at the same level, a continuous current of electricity will be maintained for some weeks. The mode of connecting this battery with the decomposing cell, is shown in fig. 43. This cell is the counterpart of the battery, consisting of two glass cylinders, A, B, the latter having a plaster of Paris bottom. The tube B, is about 3 inches long and half an inch wide, and receives the metallic or other solution to be decomposed, the outer tube A being filled with weak brine. Into this brine is plunged a strip of amalgamated zinc C, connected with the wire F, of the battery, while a strip of platinum foil D, is immersed in the metallic solution, and is connected with the wire G of the battery. This apparatus, therefore, consists of an active single battery, of which C, E, is one of the two metallic elements, and C and D the other; and the fluid between C and E, separated by the porous diaphragm D, one fluid element, and the fluid between C and D, separated by a porous diaphragm, another fluid element.[1]

Fig. 42.

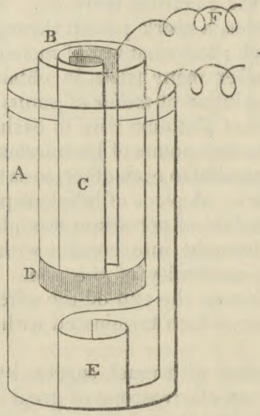

Fig. 43.

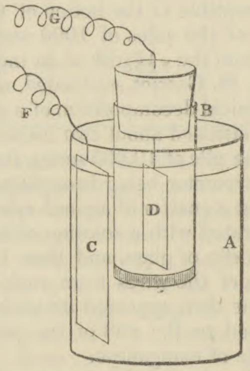
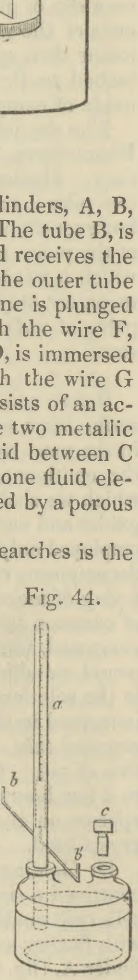


Faraday's volta meter.

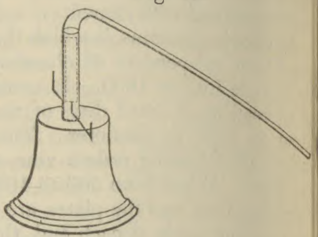
Another instrument necessary in voltaic researches is the volta-electrometer, or voltameter, invented by Dr Faraday, for measuring the quantity of voltaic electricity, by means of the quantity of oxygen and hydrogen generated by the battery. It consists of a graduated glass tube, *a*, fig. 44, closed at the upper end. Platina wires *b*, *b′*, terminating in two platinum plates within the tube, pass through the tube, and are fused into the glass. The tube is fitted by grinding into one of the necks of a two necked bottle. If the bottle is ½ or ⅔ds full of dilute sulphuric acid, it will by enclosing the tube, flow into the tube, and fill it. When an electric current, therefore, is passed through the instrument between the plates, the evolved gases collect in the upper part of the tube, without being subject to the recombining power of the platina, the stopper *c* is taken out. By receiving the wires connected with *b*, *b′*, replacing the stopper, and refilling the tube with the liquid by inverting the bottle, a second measure of gas may be obtained on replacing the wires at *b*, and *b′*.

Fig. 44.



Dr Faraday has given in fig. 45, another form of the voltameter, which he found very useful in experiments continued for days together, and where large quantities of indicating gas are to be collected. The gases, in place of being measured in the tube, as in fig. 44, are carried by the bent tube *b*, into a graduated jar, placed in a small pneumatic trough.

Fig. 45.



CHAP. II — ON THE GENERAL PHENOMENA AND EFFECTS OF GALVANISM.

In our article on ELECTRICITY,[2] we have already given a brief account of the results obtained by Dr Faraday, which established the identity of all the various kinds of electricity, and the relation by measure of ordinary and voltaic electricity, as obtained by the same distinguished philosopher, and of his new law of electrical conduction.

Notwithstanding the identity of character of *common* and *voltaic* electricity, the effects which they produce are almost infinitely varied, some of these effects being exalted while others are diminished. All these variations, however, are explicable by the differences in quantity and intensity of these two kinds of electricity.

In the case of ordinary electricity, a piece of glass or sealing-wax, excited by friction and kept near the cap of a gold leaf electrometer, will produce a great and instantaneous divergence of the leaves; but in voltaic electricity the same effect is not produced, even by a battery of 100 pair of plates.

When the extremities or poles of such a battery are examined by the electrometer, they are found to be *positive* and *negative*, the gold leaves *repelling* each other at the *same* pole, and *attracting* each other at *different* poles, even when above half an inch of air intervenes. Hence *ordinary* differs from *voltaic* electricity, in having a much higher degree of *tension*, or *intensity*, that is, in acting with a greater elastic force in a given direction. From this property it acts so powerfully on the electrometer, and is discharged with such facility through air, whether highly rarefied or heated. On the other hand, *voltaic* differs from *ordinary* electricity in the enormous quantity of electricity which it delevopes and puts in motion, and in the continuity or perpetual reproduction of the current.

In order to convey some idea of the immense difference in this respect of the two electricities, Dr Faraday has stated that "the chemical action of a grain of water upon four grains of zinc, can evolve electricity equal in quantity to that of a powerful thunder-storm." That if a Leyden battery is charged with 30 turns of a large and powerful plate electrical machine in full action, it would require 800,000 such charges to supply electricity to decompose a single grain of water, or to equal the quantity which is naturally associated with the elements of that grain of water, endowing them with their mutual chemical affinity.[3] Or to put the comparison differently, the quantity of electricity in 25¼ grains of water is equal to above 24 millions of charges of the Leyden battery above mentioned, or would keep any length of platina wire $\frac{1}{104}$th of an inch in diameter, red hot for an hour and a half.

---

[3] Faraday's Exp. Researches, p. 253, 258, and 861, 873.

We have already seen that voltaic electricity at rest, like dinary electricity, produces attractions and repulsions. e shall therefore proceed to give an account of the effects voltaic electricity in motion, or of voltaic currents.

CT. I.—*On the Conducting Power of Solids and Fluids for Voltaic Electricity.*

Conducting power.

When a voltaic battery is in a state of activity, and when wires of different metals are placed between the poles of the battery, so as to complete the circuit, the current of electricity passes through them with different degrees of facility, that is, the different metals transmit the electricity with different degrees of resistance.

The following table contains the results obtained by Davy, Becquerel, Pouillet, &c., respecting the conducting power of different metals, for different kinds of electricity.

	Becquerel.[1]	Davy.	Harris.[2]	Cumming.[3]	Christie.[4]	Pouillet.[5]
	Voltaic Electricity.	Voltaic Electricity.	Ordinary Electricity.	Thermo-Electricity.	Electricity of Induction.	Electricity of a single couple.
Copper, ...	100	100	100	100	100	100
Gold,.........	93·6	73	66·7	35·2	110	84
Silver, ...	73·6	109	100	176·5	15·2	116
Zinc,.........	28·5		33·3	53	52·2	
Platina,......	16·4	18	20	21·6	24·5	13
Iron,.........	158	14·5	20	24·3	22·3	16
Tin,..........	15·5		16·7	23·9	25·3	
Lead,........	8·3	69	8·3	16·8	12·4	brass 12

These results are, generally speaking, greatly at variance, t only ones that admit of comparison being those of Becq rel and Mr Snow Harris. Much depends on the purity o he metals; and Mr Harris has ascertained that the cond ting power of alloys is very different from that of their c ponent metals. This appears very distinctly from the n nber for brass, which bears no relation in M. Pouillet's c umn, to the measures for copper and zinc, and also from h measure for gold of 18 karats, which we find to be only t 7th of copper, and the 6th of fine gold. The conducti power in the same metal increases directly as the area o he section of the wires, and inversely as the length of t wire.

I. Pouillet has found that the same law holds in liquids i uded in cylindrical tubes. By comparing, in this way, t conducting power of different saline solutions, the cond ting wires being formed of the metal whose oxide was i olution, he found, as Fechner had done, that the intens was rigorously in the direct ratio of the section and the i erse ratio of the conductibility. In this way he found t t 433 feet of platinum wire 0·006 inch in diameter, had t same conducting power as a column of saturated solu on of sulphate of copper 3¼ feet in length, and 0·8 inch i liameter, from which it follows that the conducting p er of the platinum is *two million and a half* times g ater than that of the solution.

he following table shows the results of his observations, t conducting power of the copper solution at 59° Fahr., b g taken as unity.

				Conducting Power.
aturated solution of sulphate of copper,....				1·00
Do.	diluted with	one volume	of water...	0·64
Do.	do.	two	do.,.........	0·44
Do.	do.	four	do.,.........	0·31

istilled water,......................................				0·0025
o.	with $\frac{1}{20000}$ of nitric acid,................			0·015

I. Marianini has obtained a great number of interesting r ilts respecting the conducting power of water holding i solution different acids, alkalis, or salts, compared with t of distilled water, at the temperature of 3° of Reaumur. T e following is a selection from his results.

Distilled water, temperature, 3° Reaumur,.....	1·000
Hydrocyanate of soda,..................................	10·96
Hydrocyanic acid, ...	18·27
Liquid ammonia,..	24·45
Soda,..	32·06
Phosphate of potash,...................................	44·74
———— of Soda,..	46·00
Tartrate of potash and antimony,................	50·07
Sulphate of zinc,..	51·69
Potash,..	55·68
Nitrate of lime,..	57·00
Acetate of potash,..	59·02
Nitrate of Baryta,...	60·02
Carbonate of potash, neutral,.......................	66·07
Benzoic acid,..	70·67
Sulphate of soda,..	74·02
Sulphate of potash,.......................................	80·00
Citric acid, ...	85·71
Tartrate of potash,..	92·00
Tartaric acid,..	98·66
Sea water,..	100·00
Hydrochlorate of lime,.................................	110·00
Oxalate of potash,...	149·00
Acetate of copper,..	154·00
Oxalic acid,...	179·00
Sulphuric acid,..	239·00
Nitrate of silver.............	298·00
Nitric acid,..	358·00
Hydrochlorate of platinum,..........................	418·00

The conducting power of solutions increases as the quantity of salts dissolved, but more slowly as the solution approaches to saturation. The preceding table shows that the *acid* solutions have the *greatest*, and the *alkaline* and neutral solutions, the *least* conducting power.

Faraday.

The relation between the contractibility of non-metallic bodies in the solid state, and that of the same bodies in the liquid state, has been investigated by Dr Faraday, with his usual ability and success. Having found that a thin plate of *ice* stopped the electric current, while the same current passed when the ice was converted into water, Dr Faraday examined a great number of non-metallic solids, and found that they assumed the conducting property during liquefaction, and lost it during congelation; but what was remarkable, all those bodies underwent decomposition when

Conducting power.

fluid, with the single exception of the *periodide of mercury*, which, though it insulated when solid, and conducted when fluid, was not decomposed in the latter state. Dr Faraday found also a great variety of bodies, which acquired no conducting power in the fluid state, such as *sulphur*, *phosphorus*, &c., and they were not decomposed in this last state.

The relation between conduction and decomposition is a very important one; but no less so is the relation of the conducting power for electricity to that for heat. "As the solid becomes a fluid," says Dr Faraday, "it loses almost entirely the power of conduction for heat, but gains in a high degree that for electricity; but as it reverts back to the solid state, it gains the power of conducting heat, and loses that of conducting electricity."

Conditions of electric conduction.

Dr Faraday has given the following summary of the conditions of electric conduction in bodies:—

"1. All bodies conduct electricity in the same manner from metals to lac and gases, but in very different degrees.

"2. Conducting power is in some bodies powerfully increased by heat (such as in sulphuret of silver, fluoride of lead, periodide of mercury, and corrosive sublimate), and in others diminished, yet without our perceiving any accompanying essential electrical difference, either in the bodies, or in the changes occasioned by the electricity conducted.

"3. A numerous class of bodies, insulating electricity of low intensity, when solid, conduct it very freely when fluid, and are then decomposed by it.

"4. But there are many fluid bodies which do not sensibly conduct electricity of this low intensity; there are some which conduct it, and are not decomposed, nor is fluidity essential to decomposition.

"5. There is but one body yet discovered (periodide of mercury, to which Dr Faraday subsequently added corrosive sublimate), which, insulating a voltaic current when solid, and conducting it when fluid, is not decomposed in the latter case.

"6. There is no strict electrical distinction of conduction which can, as yet, be drawn between bodies supposed to be elementary, and those known to be compounds."[1]

Sir Humphry Davy[2] has shewn, that, as a class, metals have their conducting power diminished by heat; and Mr Snow Harris has proved, that heat does affect gaseous bodies, or at least air.[3]

SECT. II.—*On the Intensity and Direction of Voltaic Currents.*

Intensity and direction of voltaic currents.

The two electricities of the pile, when disengaged by the chemical action of its elements, tend continually to reunite and form a neutral fluid, by entering the conducting bodies in their vicinity. The quantity of electricity which remains free, constitutes the *tension* of the pile, or the intensity of the current, as we have already explained.

Intensity of currents.

The tension of the pile is affected by various causes. When its two extremities are united by a metallic arc, the tension at first diminishes rapidly, but the diminution becomes slower and slower, till it reaches its limit, beyond which the tension no longer decreases, however great is the length of time during which the circuit is closed.

The loss of tension in a given time increases with the number of voltaic couples, and the pile is longer in reaching the limit beyond which the tension does not decrease.

Marianini's experiments.

The loss of tension is more rapid when the liquid exercises a more powerful chemical action on the oxidable metal of the voltaic couple, and the longer it is in reaching the limit of decrease. In these experiments, which we owe to Marianini, the conducting power of the metallic arc has no influence.

The electric tension lost under the preceding circumstances, is again restored by opening the pile, that is, r versing the metallic arc which united its extremities; b it requires more time to recover its primitive tension, t longer the circuit has been closed.

In studying the change produced upon the tension wh the circuit is not closed by a metallic arc, M. Mariani found, that a battery with new plates loses less tension in given time, than one with oxidated plates, the new appar tus reaching its limit sooner than the old one. In piles co sisting of gold and zinc couples, tension diminishes mo rapidly than in the ordinary pile, and reaches its limit in very short time; whilst in piles with lead and zinc, t tension diminishes less rapidly than with copper and zin

The *direction* as well as the intensity of electric curren depends on the degree of chemical action exerted by t liquid on one of the metals, particularly the most oxidal one. When the liquid and the metals are therefore know the direction of the current can be predicted. The me most acted upon takes away from the liquid negative ele tricity. Zinc, for example, is more attacked by brine th copper, and therefore takes from the brine its negative ele tricity; but if the liquid is a solution of sulphuret of pota sium, which affects the copper more than the zinc, the co per will take from the solution its negative electricity, a the current will take an opposite direction. Hence, in pile with brine, the *zinc* extremity will give *positive* ele tricity; whereas, in a pile with a solution of sulphuret potassium, the *zinc* extremity will give *negative* electricit

M. Delarive obtained the following interesting resul by immersing different voltaic couples in nitric acid of d ferent strengths. Each metal in the two columns is *po* *tive* in relation to the one which precedes it.

In Concentrated Nitric Acid.	In Dilute Nitric Acid.
Oxidated iron.	Silver.
Silver.	Copper.
Mercury.	Oxidated iron.
Lead.	Iron.
Copper.	Lead.
Iron.	Mercury.
Zinc.	Tin.
Tin.	Zinc.

M. Becquerel mentions *arsenic* and *iron* as a remarkab example of a change of polarity produced by the chemic action of the fluid. With a voltaic couple of *iron* a *arsenic*, the *iron* is strongly *positive* compared with t arsenic, when they are immersed in diluted acid, whi acts slightly upon the arsenic; but when they are immers in potash kept in fusion, the *arsenic*, upon which the pota acts powerfully, becomes *positive*.

M. Delarive has illustrated this branch of science with number of valuable experiments on the changes produc upon electric currents, while passing through liquid co ductors, interrupted by metallic plates. The following a the results at which he arrived:—

1. One or more metallic laminæ (platina), placed pe pendicularly to the direction of the electric current, in liquid conductor, diminish the intensity of the curre which traverses them.

2. This diminution is almost nothing when the electr current is very energetic, and proceeds from a pile contai ing a great number of couples; but the intensity diminish the more rapidly in passing through the same number plates, as its original intensity is less energetic.

3. If one or two electrical currents of the same intensit the one an original one, and the other one which has pre viously passed through several metallic plates, the first wi have its intensity much more diminished by the interpos tion of a plate than the second. Hence, these currents hav

---

[1] Researches, § 444—449.

[2] Phil. Trans. 1821, p. 431.

[3] Id. 1834, p. 230.

the same property, (not by polarisation, as stated by Becquerel), as light and heat which have passed through absorbing media.[1] We have no doubt, therefore, that currents which have passed through plates of metals, will have thus acquired, or have possessed previous to their separation, other properties than that of passing more freely through other metallic plates.

From the preceding results, M. Delarive has explained the difference between the effects of a pile with a small number of couples, and a pile with a larger number. The first produces more easily the effects which took place when the circuit is closed by a very good conductor, while the second may be best employed in producing phenomena which take place in the circuit of an imperfect conductor, such as a fluid, the transmitted currents in the latter case having acquired, in passing through a greater number of plates, a greater facility of traversing an imperfect conductor.

As the intensity of the electric current had been found to increase with the surface, acted upon by the fluid, M. Delarive endeavoured to determine the law of increase. He found that an increase of surface facilitated the transmission of the current; that the augmentation of intensity produced by a greater extent of surface, increased in a *greater ratio than the surface* when the current is *feeble*, and in a less ratio when the current is intense; so that we gain more by increasing the surface when the current is weak than when it is strong.

With regard to the influence of fluid conductors in dinishing the intensity of the electric current, M. Delarive und that nitric acid diminishes the intensity least, then uriatic acid, then sulphuric acid. Nitric acid, pure and eatly diluted, produces a less diminution than concenated acid. The contrary takes place with sulphuric acid, hich is a bad conductor. The silver solution came next, en potash and ammonia, which differ little from each her.

Universelle* for 33. See especially Becquerel's *Traité de l'Elect. et agnet.* tom. iii.

CT. III.—*On the Production of Light, Heat, and Cold by Voltaic Electricity—the Ignition of Wires.*

The phenomena of light and heat, and the ignition of etals and wires by ordinary ELECTRICITY, having been lly described under that article, we shall here confine ourlves to the analogous phenomena produced by voltaic rrents.

Soon after the discovery of the pile, Van Marum, Pfaff, d Tromsdorff discovered that thin leaves and fine wires of etal placed between the poles of a pile, became incandesnt, and even burned while conducting the electrical current; and some time afterwards, M.M. Fourcroy, Vauquen, and Thenard observed that piles with large plates degrated metals more powerfully than piles with a great umber of plates of smaller surfaces.

It was in England, however, that the calorific and luminous effects of the pile were principally developed. In 813, the immense battery of the Royal Institution, composed of 2000 couples, and exposing 28,000 square inches, enabled Sir H. Davy to produce light and heat of the highest intensity. When the ends of the wire from each pile terminated in two charcoal points, the most dazzling light passed from the one to the other, and continued for several hours. Platina, sapphire, quartz, and lime, &c., when exposed to this source of heat, were instantly melted, and the diamond and charcoal disappeared, as if they were completely volatilised; and these effects were produced in vacuo as well as in air.

Davy.

By means of the splendid battery described in a preceding part of this article, Mr Children obtained many important and curious results. His experiments commenced in 1809, but it was in 1815 that he brought into play the powerful instrument which we have already mentioned. He found that metallic wires connecting the two piles of the battery became red-hot in the following order:—

Children.

Platinum.	Copper.	Zinc.
Iron.	Gold.	Silver.

And hence Mr Children concluded, that the conducting power of these metals was in the inverse order, silver being the most conducting, and platinum the least.

With this battery, five feet six inches of platinum wire, 0·11 inch in diameter, were brought by Mr Children to a red heat throughout, so as to be visible in day-light.

Eight feet six inches of platinum wire, 0·44 inch in diameter, were heated red.

A bar of platinum $\frac{1}{6}$th of an inch square, and 2·25 inches long, was heated red, and fused at the end.

The oxides of tungsten, uranium, cerium, titanium, and molybdenium, were fused. Having filled an opening in an iron wire with diamond powder, the diamond disappeared, and the iron was converted into steel.[2]

At the same time that Mr Children was constructing the greatest voltaic battery ever made, Dr Wollaston was occupied in constructing the smallest. He took a small thimble, and having removed the bottom, he flattened the remaining cylinder, till its sides were about $\frac{1}{6}$th of an inch distant. He then placed between these two surfaces a small plate of zinc, which did not touch either side of the thimble. With a platinum wire about $\frac{1}{40}$th of an inch long, and $\frac{1}{3000}$dth of an inch in diameter, he united externally the plate of zinc with this thimble; and when this little galvanic couple was immersed in acidulated water, the platinum wire became red-hot, and was melted! This important result led Dr Wollaston to the valuable conclusion, that in order to obtain powerful calorific effects, we must increase the surface of the copper in negative metal.

Wollaston.

In repeating the experiments of Davy on the light developed by charcoal points, M. Brandes discovered that this light, like that of the sun, affected the combination of chlorine and hydrogen, and the decomposition of muriate of silver and other bodies.

Brandes.

By means of the powerful voltaic battery, which Dr Hare calls a *deflagrator*, and which we have already described, this able chemist obtained some splendid results. A brilliant light, equal to that of the sun, was produced between charcoal points; and plumbago and charcoal were fused by Professors Silliman and Griscom. By a series of 250, baryta was deflagrated; and a platina wire, $\frac{3}{16}$ths of an inch in thickness, "was made to flow like water." In the experiments with charcoal, the charcoal on the copper side had no appearance of fusion, but a crater-shaped ca-

Hare.

Fusion of charcoal.

---

[1] M. Becquerel, to whose excellent work we are indebted for the latest and best information on this subject, asks, "if we will from alogy say, that the current, in traversing different plates, *acquires* a polarisation similar to that of light." Certainly not. When white ght passes through a certain thickness of any coloured medium, or any similar number of coloured plates, it loses a certain portion of its ys, say 9-10ths, and the transmitted light is red. Now, this *red* light may be transmitted through the same number of the same plates, d yet not lose 1-10th of its light; but there is no polarisation. The first plates absorbed all the rays but the red, and having the property of transmitting the red rays freely and more copiously than any other, they passed through in greater abundance. As these transmisons are all at a vertical incidence, polarisation can have nothing to do with the matter.

[2] See Phil. Trans. 1815.

vity was formed within it, indicating that the charcoal was volatilised at this side, and transferred to the other, where it was condensed and fused, the piece of charcoal at this pile being elongated considerably. This fused charcoal was four times denser than before fusion.

Owing to its superior conducting power, a continued voltaic current will maintain, in a state of incandescence, a greater length of silver wire than of platinum or iron; but if we form a wire of short pieces of silver and platinum wire alternately, the platinum portion will become red-hot, while the silver ones remain cold. In this case, the current which passes readily along the silver wire, encounters the degree of obstruction in the platinum which produces the red heat. This fact is no doubt connected with the very remarkable one observed by M. Peltier, in the passage of weak currents through metallic circuits, where *cold* was produced at the points of junction of certain crystallizable metals.

Peltier.

SECT. IV.—*On the Chemical Effects of Voltaic Electricity.*

Chemical effects of voltaic electricity.

Nicholson & Carlisle.

In a preceding article we have given a full account of the general chemical effects of *ordinary electricity*. We shall therefore confine ourselves at present to the chemical effects of the voltaic pile. No sooner was this apparatus made known in England, than Messrs Nicholson and Carlisle applied it to chemical inquiries. Although Volta had inferred from the shock, that the action of the pile was electrical, yet it was to the above inquirers that we are indebted for determining by means of the revolving doubler, that the *silver* end of the battery was in a *negative*, and the *zinc* end in a positive state of electricity. In the course of their experiments, they observed a disengagement of gas, which smelt of hydrogen, from water which happened to be in the circuit; and on the 2d of May 1800, they discovered that water was decomposed into its elements, viz. oxygen and hydrogen, when the water formed part of the circuit between the positive and negative ends of the pile. Mr Cruickshanks of Woolwich confirmed this result, and found that *hydrogen* was always emitted from the *silver* or *copper* end of the pile, and *oxygen* from the other. He discovered also the important fact, that metals could be revived from their solutions, under the same circumstances, the reduced metal being deposited at the end of the wire; and he succeeded in decomposing some of the neutral salts. Dr Henry decomposed the nitric and sulphuric acids and ammonia; and he reduced the oxymuriatic to the state of muriatic acid.

Decomposition of water.

Cruickshanks.

Henry.

Davy.

The attention of our illustrious countryman, Sir H. Davy, was about this time attracted to the subject. So early as 1802, he had made experiments on the chemical agency of the pile; but in 1806, in his first Bakerian Lecture, he was led to the conclusion, *that chemical attraction and repulsion were produced by the same cause, acting in the one case on particles, in the other on masses, and that the same property, under different circumstances, was the cause of all the phenomena exhibited by different voltaic combinations.* In October 1807, he decomposed potash and soda, and proved that they were oxides of two new metals, *potassium* and *sodium*. With a voltaic battery of 2000 plates, he decomposed several of the earths, and discovered their metallic bases, *barium, strontium, calcium,* and *magnesium*. In attempting to decompose the proper earths, he was less successful. He succeeded in proving, however, that they consist of bases united to oxygen, but the completion of the inquiry was left to Wohler, Bussy, and Berzelius, who found that all the bases of these earths, except silica, were metallic, and capable of uniting with iron.[1]

Our narrow limits will not permit us to give an account of the successive labours of different philosophers, in effecting decompositions by the voltaic battery. We shall content ourselves with giving a brief account of the researche of our distinguished countryman, Dr Faraday, to whom thi branch of science owes its greatest acquisitions.

The phenomena of electro-chemical decomposition hav been generally ascribed to two opposite powers residing i the two poles of the voltaic battery. Grotthus[2] regards th pile as an electric magnet with *attracting* and *repellin* poles, the one attracting hydrogen and repelling oxygen and the other attracting oxygen and repelling hydrogen The force exerted upon each molecule of the body is supposed to be inversely as its distance from the poles, and succession of decompositions and recompositions is supposed to exist among the intervening molecules. Sir H Davy adopts the idea of attractions at the poles, diminishing to the middle or neutral points, and he thinks a succession of decompositions and recompositions probable. Messr Riffault and Champre regard the *negative* current as collecting and carrying the acids on to the *positive* pole, and the *positive* current as doing the same, with the bases towards the *negative* pole. M. Biot attributes the effects to the opposite electrical states of the decomposing substances in the vicinity of the two poles. M. de la Rive considers the portions decomposed to be those contiguous to both poles, the current from the *positive* pole combining with the hydrogen or the bases which are there present, and leaving the oxygen or acids at liberty, but carrying the substances in union with it across to the negative pole, where it is separated from them, entering the conducting metal, and leaving on its surface the hydrogen, or its bases. Dr Faraday regards the poles as exercising no specific action, but merely as surfaces or doors by which the electricity enters into or passes out of the substance undergoing decomposition. He supposes that "the effects are due to a modification of the electric current, and the chemical affinity of the particles through or by which that current is passing, giving them the power of acting more forcibly in one direction than in another, and consequently making them travel by a series of successive decompositions and recompositions in opposite directions, and finally causing their expulsion or exclusion at the boundaries of the body under decomposition in the direction of the current, and that in larger or smaller quantities, according as the current is more or less powerful."

In resolving a compound body into its elements, liquidity is an essential condition of the body. A plate of iron, the 16th of an inch thick, placed between the two sides of the pile, will stop completely the most powerful electrical current.

When the elements of a body are separated by electric action, the current communicates to each a definite direction, the oxygen travelling towards the zinc, and the hydrogen towards the platina pole.

By an irresistible body of evidence, Dr Faraday has established the important proposition, "that the chemical power of a current of electricity is in direct proportion to the absolute quantity which passes;" and this is true of all bodies capable of electro-chemical decomposition.

The same eminent philosopher has also deduced, from a variety of facts, the following conclusion, "that the quantity of electricity, which, being naturally associated with the particles of matter, gives them their combining power, is able, when thrown into a current, to separate these particles from their state of combination; or, in other words, that *the electricity which decomposes, and that which is evolved by the decomposition of a certain quantity of matter, are alike.*" According to this theory, "the equivalent weights of bodies are simply those quantities of them which contain equal quantities of electricity, or have naturally equal electr powers, it being the *electricity* which determines the ec ivalent number, because it determines the combining fc e; or if we adopt the atomic theory or phraseology, th the atoms of bodies which are equivalents to each ot er in their ordinary chemical action, have equal quanti ti of electricity naturally associated with them.”

---

[1] See our articles CHEMISTRY and DAVY, for a full account of Sir Humphry Davy's electro-chemical researches.

Ann. de Chim. 1806, tom. lviii. p. 61.

Vhen exposed to the voltaic current, bodies are decompe ed with different degrees of facility. Dr Faraday found b experiment, that the following bodies were decomposed w currents of different intensities, those at the top of the li being decomposed by currents of lowest intensity.

Io de of potassium (solution.)
C oride of silver (fused.)
P o-chloride of tin (fused.)
C oride of lead (fused.)
Iodide of lead (fused.)
Muriatic acid (solution.)
Water acidulated with sulphuric acid.

ll compound bodies are not decomposable by electric cu ents. The following bodies are not decomposed under or nary circumstances :—

C orides of sulphur, phospho- s, and carbon.
Boracic acid.
Iodide of sulphur.

he following bodies are not decomposed :—

C oride of antimony.
H lro-carbon.
A tic acid.
Periodide of mercury.
Ammonia.

ll solid non-conductors which become conductors when li ified by heat, with the exception of *periodide of mer-cu*, are decomposed.

Ir Faraday is of opinion that all *binary compounds*, one ot hose elements goes to the *negative*, and the other to th *positive* pole, are decomposable, but not ternary compc nds.

he following bodies, being non-conductors of electricity, ar not decomposed by it.

S huric acid.
P sphoric acid.
A enic acid.
H o-nitrous acid.
Nitric acid.
Chloride of sulphur.
Proto-chloride of phosphorus.
Proto-chloride of carbon.

he perchlorides of mercury and of antimony, being cc ductors when liquid, are decomposable, but periodide o ercury, though a conductor when liquid, is not decomp ble.

he following bodies are not decomposable by voltaic el tricity:—

N e.
N ate of ammonia.
S burous acid.
H rofluoric acid.
F orides.
A tates.
Tartaric acid.
Tartrates.
Benzoides.
Sugar.
Gum.

he following table contains a list of the elementary cc stituents of decomposable bodies, with their electroc mical equivalents[1] :—

Elements which go to the POSITIVE *Pole.*

		Potassa	47·2		

Combination of gases by metals.

In the course of his electrical researches, Dr Faraday[2] discovered the very remarkable fact, that metals and other bodies had the power of promoting the combination of gaseous bodies. When a plate of clean platinum was put into a mixture of oxygen and hydrogen gas, the two gases gradually disappeared, in consequence of having united and formed water. When the platinum plate was made very clean, by placing it in sulphuric acid, it acted with such energy on the gases, that the tube became warm, the platina became red-hot, and the residue of the gases was inflamed. A solution of tartaric or acetic acids gave the platinum plate the power of producing explosion in the mixed gases, but strong sulphuric acid was most certain and powerful. *Gold* and *palladium*, when acted on by hot oil of vitriol, possess also the power of combining oxygen and hydrogen.

Dobereiner Instantaneous light apparatus.

Dobereiner had previously discovered the remarkable property possessed by platinum, which, in the state of a fine black powder, or spongy, became hot, and ignited a jet of hydrogen. This is the well known instantaneous light apparatus. The following is the theory of these remarkable facts. The particles of hydrogen repel each other, so do those of oxygen; but the strong adhesion of the gaseous particles to the platina suspends, as it were, upon its surface, the above repulsive forces, and brings the particles of oxygen and hydrogen within the influence of their mutual affinity.

Spongy platinum also decomposes ammonia, and its salts when mixed with atmospheric air, and passed over the metal at 572° of Fahr. Non-metallic bodies, such as pounded glass and charcoal, have, at 600° Fahr., the same property as platinum.

SECT. V.—*On Electro-chemical Decompositions by weak Electric Currents.*

Effects of weak electric currents.

The precipitation of metals from their solutions, by the presence of other metals, has been long known. A plate of copper, for example, will throw down metallic silver from a solution of the nitrate. Ritter, Sylvester, and Bucholz found that these precipitations were owing to electric currents, and obtained some interesting results. It is to M. Becquerel, however, a distinguished member of the Institute of France, that we owe the successful investigation of this curious subject. In 1826, he found that, by very feeble electric forces, metals easily reducible were precipitated from their solutions, by plates of the same metal as that held in solution. In 1627, he formed chlorides and iodides in the same way, and also double chlorides and double iodides. In 1829, he succeeded in forming sulphurets, iodides, and bromides by similar methods; and when the electric energy of the apparatus was exceedingly feeble, and the decomposition slow, the sulphurets had time to assume a regular crystalline form, and he thus obtained crystals of almost all the metals. In a similar manner, he obtained distinct crystals of the metallic iodides.

Discoveries of M. Becquerel.

In 1830, M. Becquerel found that new compounds were formed during these processes, by the reaction of the oxide of the metal at the positive pole of a solution. By the reaction of two solutions, one of which was the sulpho-carbonate of potash, and the other the sulphate of copper, and by employing an arc of copper and lead, the copper plunging into the sulphate, and the lead into the sulpho-carbonate, he succeeded in depositing on the lead small octohedral crystals of sulphur, with rhomboidal faces, exactly si-

---

[1] Faraday's Experimental Researches, p. 247, § 846.

[2] Id. Id. p. 195, § 564, &c.

Discoveries of M. Becquerel.

milar to the natural crystals of this substance. In this manner, by a skilful combination of solutions and metallic arcs, and a profound knowledge of the reactions which arise from the contact of these different substances, he succeeded in obtaining, in a crystalline state, compounds which had never been procured under that form.

M. Becquerel has been equally successful in reducing the bases of certain oxides, and in obtaining immediately from their solutions, in their metallic, and even crystallised state, iron; zirconium, glucium, and magnesium. In 1832, he also obtained crystals of metallic oxides, such as those of the anhydrous black oxide of copper, of the red oxide, of the protoxide and peroxide of lead, and the oxide of cobalt.

The same distinguished philosopher has employed the effects of weak electric forces to explain the process of cementation, by which iron is converted into steel, by the combination of carbon with all the interior molecules of the iron; and that remarkable mineralogical process by which the elements of many rocks are transferred from within to without, and replaced by others without any disintegration. The process of cementation is the consequence of the opposite electric state of the carbon and the iron, which, with the aid of high temperature, produces electric currents that convey the atoms of carbon from molecule to molecule to the very interior of the iron. In like manner, pieces of iron, which have been buried in the metallic state, are almost wholly oxidated; and ancient copper medals have been found changed entirely into the protoxide of copper.

Phosphorescence.

By studying this class of phenomena, M. Becquerel has been led to an explanation of the phenomena of phosphorescence, which he ascribes to the recomposition of the natural electricities of each molecule, which have been separated by heat or some other cause. The restoration of phosphorescence to bodies that have lost this property, or that never possessed it, by repeated electrical discharges, as ascertained by Mr Pearsal, confirms the ingenious explanation of M. Becquerel.[1]

Mr Crosse's experiments.

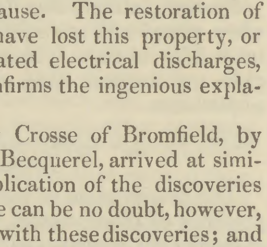
Our countryman, Mr Andrew Crosse of Bromfield, by processes differing from those of Becquerel, arrived at similar results, not long after the publication of the discoveries of the French philosopher. There can be no doubt, however, that Mr Crosse was unacquainted with these discoveries; and that his results were entirely independent of them. By means of voltaic electricity, he obtained the following substances, namely, calcareous spar, arragonite, quartz, red oxide of copper, arseniate of copper, blue carbonate of copper, phosphate of copper, sulphuret of copper, carbonate of lead, sulphuret of silver, carbonate of zinc, chalcedony, oxide of tin, yellow oxide of lead, the sulphurets of antimony and zinc and iron, protoxide of iron, and crystals of sulphur.

SECT. VI.—*On the Coloured Rings formed on Polished Metallic Plates by Voltaic Currents.*

Nobili's experiments on metallic colours.

This new class of phenomena are remarkable from their beauty and singularity, as discovered by M. Nobili. They may be produced by a small battery like that of Wollaston, with twelve elements of an inch square, in the manner shown in fig. 46. A small apparatus, not shown in the figure, is constructed so as to move up and down the pincers R S, which hold two pieces of large platinum wire P N, pointed at their extremity, the one communicating with the positive, and the other with the negative pole of the battery. A polished metallic plate A B, intended to receive the coloured rings, is placed horizontally in a saucer or plate which contains the fluid to be used, suppose a solution of sulphate of copper.

Fig. 46.



When the solution of copper is poured into the saucer above the silver plate AB, and the point of one of the wires N brought as near as possible to *n*, while the other point *p* is plunged in the solution, there will be formed round the point *n*, *four* or *five* concentric circles, alternately bright and dark. When the point *p* is used, there will be formed round it *three* small circles of copper. The *two* extreme circles are of a deep red colour, and the middle one of a higher colour; sometimes *four* or *five* are formed, which alternate like the preceding.

When a solution of *acetate of lead* is used, and the plate of gold or silver is positive, while the point is negative, the concentric rings are as brilliant as the coloured rings of Newton. When we increase the number of negative points, there are formed as many systems as there are points of concentric wires or rings which never cross each other but which, when they meet, extend outwards so as to form only one exterior ring.

The effects are the reverse with a solution of *acetate of copper*, that is, the concentric rings are formed only when the plates are negative, while positive plates exhibit nothing remarkable.

When the fluid is *urine* and the plate silver and positive, several orders of very brilliant-coloured rings are formed round a dark centre. M. Nobili has obtained very remarkable effects of colour by using different animal substances, such as milk, white and yoke of an egg, saliva, &c. and vegetable substances, such as the juice of carrots onions, parsley, grapes, apples, &c. Animal and vegetable substances yield colours more beautiful and brilliant than ordinary chemical solutions. The colours produced by the leaves of plants are more marked than those arising from the decomposition of the roots. In some chemical solutions the phenomena are equally beautiful on the positive as on the negative plate; but when the circles meet, the two figures experience, as it were, a sort of compression, and when the coloured rings are impressed only on one plate they may be made to disappear, if not wholly, at least in part by inverting the direction of the current.

M. Nobili has drawn the following conclusions from a great number of experiments:—1. Certain electro-negative substances possess the property, in some circumstances, of attaching themselves to the surface of some of the less oxidable metals, in layers so thin and regular as to exhibit under an infinity of varied forms, the beautiful phenomena of coloured rings. 2. That when electro-negative substances do not deposit themselves in thin layers on polished metals, they attack their surface, not uniformly, but at regular intervals.

The most varied and remarkable appearances were obtained by M. Nobili when the polished metal was positive but he succeeded in obtaining equally remarkable phenomena when the metal was negative, either by augmenting the force of the current, or by using compound solutions.

He took, for example, a mixture of acetate of copper and nitrate of potash, and upon a negative plate of silver he formed a series of concentric rings, the centre of which retained the metallic brilliancy. The two next circles were green, then came rings of white, red, and green, then a zone of copper of a fine red colour. This zone was surrounded with a blue circle, marked with radiating lines, like a graduated circumference, its rays extending even to the circle of copper: Then came a second copper zone wider than the first, but equally brilliant, surrounded with a circle of beautiful green, which terminated the figure. The same appearances were obtained on gold and platina.[2]

ECT. VII.—*On the Physiological Effects of Voltaic Electricity.*

he effect of voltaic electricity on animal bodies is analo us to that of ordinary electricity, a subject which we ha already treated at considerable length.[1]

he galvanic shock is not conveyed through the skin of th human hand in the same manner as the electric shock. T s arises from its low intensity, in consequence of which it n be transmitted only through good conductors. The be way is to grasp with both hands wet, two silver spoons, or vo metallic belts, and by means of them form a connectio between the poles of the battery.

luminous spark is produced by voltaic electricity, when th eye forms part of the circuit. This may be done by pl ing a piece of silver between the gums and the upper li and inserting a silver probe into the nostrils. If a piece of inc is then laid upon the tongue, and the two metals br ught into contact, the flash will be seen. This, and ot r affections of the eye, were observed by Ritter, who de ares that when the positive pole was inserted, in his ey he *saw objects darker and less*, and when the negative po acted upon the eye, he saw the same objects *brighter* a *larger*. But according to Purkinje, the only differen e is, that the *positive* pole excites less light than the ne ative pole. Purkinje also observed, that by the applica on of the positive pole to the eye, a *yellow* light was ex ted, while the *negative* pole excited a *violet* light, br hter and more abundant than the yellow. He also obse ed that the luminosity was excited principally at the ba of the optic nerve, and at the *foramen centrale* of the re a. With the *positive* pole the base of the nerve exhi ted a bright *violet* light, and the dark foramen was surro ded with a double rhomboidal limb of *yellow* light; bu with the *negative* pole the base of the nerve was *black*, an the foramen was *violet*, and surrounded with a *violet* rh mboidal limb, at a little distance from the foramen. H noticed also, that when the voltaic circuit was broken, th preceding colours passed into their opposite or comple m tary ones.

a living leech, or an earthworm, is placed upon a cr wn piece, laid upon a piece of zinc of a larger size, it ex eriences no uneasiness while it touches the silver only; bu when it stretches itself, and touches the zinc, it inst tly draws itself back, as if it had received a shock.

he influence of voltaic electricity upon the muscles of an nals after death, is very remarkable. This subject has b n recently investigated by Marianini, Nobili, Peltier, an Becquerel; but our limits will not permit us to give e n the shortest account of their labours.[2] We must co tent ourselves with mentioning a few interesting facts. If he negative and positive wires are inserted in the ears o n ox or sheep taken from the body of the animal recently illed, strong convulsive motions will be excited in the m cles of the face, whenever the circuit is completed, p ided the battery have an hundred pair of plates. Life se ns to be restored, and the animal to be under great su ering. The eyes open and shut, and roll in their socket the pupils dilate; the nostrils expand and vibrate; an the jaws move as in mastication. If a horse is subje ed to powerful galvanic action, when recently killed, th struggles of its limbs can scarcely be restrained by seve l persons.

Voltaic Electricity.

Dr Ure's experiments.

imilar experiments were made in Glasgow in 1811, by D Ure, on the body of a criminal after execution. He u a battery of 270 pair of four inch plates. When the sp al marrow and sciatic nerve were made the points of co munication with the positive and negative poles, the whole body shuddered as with cold. The left side was most powerfully convulsed; and upon moving one of the rods from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to knock over one of the assistants. By acting upon the nerves connected with the respiratory system, a laborious breathing instantly commenced, and the chest heaved and sunk. When a communication was made between the superorbital nerve and the heels, "most extraordinary grimaces," says Dr Ure, "were exhibited, by running the wire in my hand over the edges of the plates in the last trough, from the 220th to the 278th pair. Thus, fifty shocks, each greater than the preceding ones, were given in two seconds. Every muscle of his countenance was simultaneously thrown into fearful action. Rage, horror, despair, and anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period, several of the spectators were obliged to leave the room, from terror or sickness, and one gentleman fainted." The last experiment made by Dr Ure consisted in transmitting the voltaic current from the spinal marrow to the ulnar nerve. "The fingers now moved nimbly, like those of a violin performer. An assistant who tried to close the fist, found the hand to open forcibly in spite of his efforts. When one rod was applied to a slight incision on the top of the fore finger, the fist being previously clenched, the fingers extended instantly; and from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life." In these experiments the *positive* wire communicated with the *nerve*, and the *negative* with the *muscles*.

Becquerel.

M. Becquerel mentions the effect produced by a pile of 100 plates, upon the head of a person who had been guillotined. The two poles of the pile communicated with the two ears, wetted with salt water. The muscles of the face experienced the strongest contractions, and the action of the eye-lids was extremely distinct. Aldini obtained analogous, though feebler effects, in experiments on a body after a natural death. Experiments of a similar kind have been made upon insects and fishes. M. Zanotti of Bologna, having killed a cigala, (grasshopper,) he placed it in contact with the two extremities of the pile, when it immediately moved, and emitted the sounds which are peculiar to it. M. Becquerel mentions also, that a fish whose head had been cut off half an hour before, struck the table with its tail, when excited by the voltaic current, and its whole body leaped about the table.

SECT. VIII.—*On the Secondary Agency of Electric Currents.*

Secondary agency of electric currents.

Dr Faraday has shown that many cases of voltaic decomposition of substances held in solution by water, such as nitric acid, ammonia, &c., are due not to the direct action of the current, but to the secondary agency of the elements of decomposed water. He, however, conceived that the hydracids in solution are directly decomposed by the current. Mr Connell has endeavoured to show that the decomposition of these substances also is secondary. This he did by connecting them by asbestus with distilled water, and making the acid negative and the water positive, when it was found that no chlorine or iodine was carried to the positive pole until after some time, when the acid itself had been carried over; whereas, when the battery was reversed so as to cause evolution of oxygen in the acid solution, chlorine or iodine immediately appeared by the combination of the nascent oxygen with hydrogen of the hydracid. From an extensive series of experiments on solutions in water, alcohol, and other solvents, Mr Connell has been

Experiments of Professor Connell.

[1] See ELECTRICITY, vol. viii. p. 609, &c. and p. 638, &c.

[2] See Becquerel's Traité, &c. tom. iv. p. 211—255, for full and interesting details on this branch of the subject.

Experiments of Professor Connell.

led to the general conclusion, that "when solutions of primary combinations of elementary bodies in water, and in those liquids, such as alcohol and pyroxylic spirit, which contain water as such as an essential constituent, are submitted to voltaic agency, the dissolved substance is not directly decomposed by the current, but only the water of the solvent." The rule of course does not include solutions of combinations of the second order, such as ordinary salts, consisting of an acid and an alkali, but those of primary compounds of elementary bodies, such as acids, alkalies, &c.[1]

When absolute alcohol, holding a minute quantity of pure caustic potash in solution, such as $\frac{1}{500}$, is subjected to moderate voltaic agency, hydrogen gas is evolved from the negative pole, and no elastic fluid from the positive; and if a powerful battery, such as 200 pairs of four-inch plates, is employed, the same effect is obtained with absolute alcohol holding nothing in solution. A long investigation showed that this result is due to the direct voltaic decomposition of the water entering into the constitution of absolute alcohol; its hydrogen being evolved at the negative pole, and its oxygen being engaged in producing various secondary changes on the hydro-carbon of the alcohol. The effect of the potash is merely to give conducting power to the alcohol, and to favour the secondary action by its affinity for some of the secondary products. The addition of a minute quantity of potassium answers better than that of the hydrate of potass, because we thus, by the oxidation of the potassium, in effect add anhydrous potass, and avoid any addition of water, although in reality the water of the hydrate has no influence whatever on the result. Even $\frac{1}{10000}$ of potass has a very decided effect in promoting the voltaic agency, and various other saline bodies when dissolved promote the action by increasing the conducting power. These experiments, it is conceived, prove *directly* what had previously been very generally *inferred*, that water as such enters into the constitution of absolute alcohol. A similar conclusion was drawn from similar experiments on the analogous substance, pyroxylic spirit.

It was found that pure rectified ether showed no symptom whatever of decomposition, when acted on by 200 pairs of four-inch plates; nor did the previous solution in it of as much caustic potass as it could take up, lead to any action of the voltaic current. It was therefore concluded that ether is not a hydrate.[2]

SECT. IX.—*On the Application of Voltaic Electricity to the Arts.*

Application of voltaic electricity to the arts.

There is perhaps no science, not even excepting chemistry, which has made such donations to the fine and useful arts as voltaic electricity. Those which depend on galvanism are the art of protecting the copper sheathing of ships; the galvano-plastic art, or that of multiplying works of art in metals, electro-metallurgy, and the reduction of the metals, the electrotype, or the art of copying and multiplying engravings, and galvanic etchings.

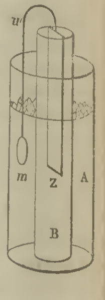
Protection of copper sheathing.

1. *Protection of Copper Sheathing.* This art, invented by Sir H. Davy, has been already sufficiently described in our article, DAVY, vol. 7, p. 662.

Voltatype, or electrotype.

2. *The Art of Multiplying Works of Art in Metal.* This beautiful art seems to have been invented about the same time by Mr Jacobi of St Petersburg, and Mr Spencer of Liverpool. Mr Jacobi, who announced his discovery in October 1831, called it the galvano-plastic process, and Mr Spencer had, previous to the knowledge of Mr Jacobis' labours, executed medals in copper, which were called electrotypes or voltatypes. Both Mr Jacobi and Mr Spencer had confined their invention to the deposition of copper upon metallic bodies; but Mr Murray announced in January 1840, that non-conducting substances, such as *plaster of Paris, wax, wood, &c.*, might have metallic copper thrown down upon them by previously *metallising* their surface with black lead.

Fig 47.



The single cell apparatus for taking casts of coin and medals is shewn in fig. 47, which consists of an outer vessel A, containing a saturated solution of sulphate of copper, and some undissolved crystals of the sulphate suspended near the upper surface of the fluid. The medal *m*, to be copied, is suspended in the copper solution. The inner vessel B, made of porous earthenware, contains the usual dilute acid, which acts upon a rod or plate of zinc Z, the upper end of which is connected with the bent wire *w* which suspends the medal *m*. When the medal has remained two or three hours in the copper solution, the copper will be found to have deposited itself on every part of its surface, so as to afford a perfect intaglio or *hollow* impression of the medal. If the surface of the medal or any part of it is greased, no copper will be deposited on the greased part. The obverse and reverse of the coin or medal being thus copied, and the two retained at their proper distance, the next step is to place them at *m* in the copper solution, and we obtain in the same manner a *raised* impression from the intaglio one, accurately resembling the original.

Instead of obtaining the intaglio cast directly in copper it is thought best to take it either in fusible or type metal, or in some non-conducting substance, such as sealing wax, bees' wax, rosin, plaster of Paris, stearine, &c. When non-conducting substances are employed, those which are absorbent, such as plaster of Paris, must be prevented from absorbing the fluid, by rubbing the surface of the intaglio mould with tallow or spermaceti; they are then to be metallised by covering their surface with black lead.

When we wish to form gold and silver medals, a gold or silver surface is necessary, as non-conducting bodies are not well fitted for this branch of the art. For a gold medal, a strong nitro-muriatic solution of gold should be used, and the medal to be copied should, according to Mr Smee, be connected with the zinc end of a series of from four to twelve batteries. A very fine platinum wire, according to the same author, immersed in the solution[3] to a trifling depth, must be united to the platinised silver of the battery, and the deposit of gold will then take place. For silver medals a solution of the nitrate, sulphate, or acetate, may be used. The solution should be weak at first, and then gradually increased. If we do not wish to have the whole medal of solid gold and silver, a thin layer may be deposited, and the rest completed by copper. On the same principles medals of platinum or palladium may be formed from their solution. Great care must be taken to prevent bubbles of air from forming on the mould.

The difficulty of coining large medals gives great value to this art. Mr Smee mentions a very fine medal of Boulton, about four inches in diameter, which required no less than 300 blows to insure a perfect impression. Seals, p ster casts, and various other works of art, may be copied in :opper and other metals by the above process.

---

[1] Transactions of the Royal Society of Edin., vol. xiii., xiv., and xv.

[2] Transactions of the Royal Society of Edin., vol. xiii., and xiv., and Lond. and Ed. Jour. Dec. 1841.

[3] In Mr Smee's ingenious battery, the negative plate which he makes of platinum or silver is roughened with sand paper; or in the case of silver, with nitric acid, and this roughened surface is covered by galvanic agency, with the finely divided black powder of platinum for the purpose of increasing the solution of hydrogen. For these purposes platinized silver is now manufactured for sale. See Smee's *Elements of Electro metallurgy.* Lond. 1841, p. 17, 18.

. *On the Multiplication of Engraved Copper Plates.* T e difficulty of procuring good and pure copper plate for e raving, has been entirely removed by this new art. A p pared copper plate with a good surface may have copper d osited on its surface, so that the deposited plate has the sa e perfect surface, with the additional advantage of consi ng of pure copper. It is advisable, however, to ham m and prepare with charcoal the deposited plate to give it asticity, &c., and such plates have been found superior to ll others for the purposes of engraving.

Fig. 48.

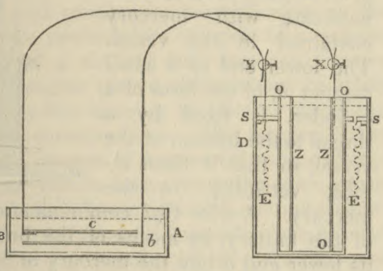


Fig. 49.

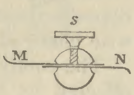


he method of copying *engraved* copper plates, of the m t delicate execution, is shewn in fig. 48, where D is a ve el, a gallipot for e mple, about ei t inches high an six inches inte al diameter. T dotted line, E , is a copper cyli er six and a half in es high and five in diameter, and O O is a porous cy nder, which may b made of brown pa er when a quick action is wanted, but, in general, a in unglazed gallipot is preferable. A cylinder of zi , Z Z, as large as possible, is then placed within the po us cylinder without touching it, nearly at the dista e of one-8th of an inch. A perforated cover, S S of ea henware, is made to rest either on the copper cylinder E , or upon a rim in the gallipot about an inch from its to The object of it is to hold crystals of sulphate of copp for keeping the solution in a state of saturation. Wires X Y, are soldered to the cylinders of copper and zinc, and th e are connected with the wires in the other vessel by a b ding screw *s*, fig. 49, used by Mr Spencer, uniting the two w es M, N. The square cell A B, contains th engraved plate *b*, to be copied, and c nected by the wire, *b x*, with the zinc c nder of the battery; and *c b* is the plate to e oxydised and to be attached to the zi cylinder of the battery. The second ar cell, or precipitating trough, which m be made of earthenware, wood, or glass, is fille ith a saturated solution of sulphate of copper. In this w a reverse copy of the plate itself is obtained in relief, a from this copy, or relief, another copy in intaglio is t e taken by the same method. It is considered preferab , however, to take a perfect mould from the engraved pl e in white wax or plaster of Paris. When this mould is ubbed with black lead, an electrotype plate is then dep ted upon it. In like manner steel plates may be copied b irst taking moulds from them in lead, wax, or plaster. It a curious fact, that the deposited plate is always superior to e engraved plate. Mr Palmer has succeeded in thus c ying the works of our finest engravers. For farther in rmation on this subject, see Spencer's *Instructions for t Multiplication of Works of Art in Metals*, &c., in Griffin's M cellany, Glasgow, 1840; *Jacobi's Die Galvanoplastik*, P ersburgh, 1840; *Annales de Chimie et de Physique*, S tember 1840, tom. lxxv. p. 24; and Smee's Elements o Electro-Metallurgy, Lond. 1841.

. *Voltaic Etching.* In this new art, which is fully d cribed by Mr Smee, the copper plate having the design d wn upon the etching ground, as in ordinary etching, and h ing its back and sides coated with wax, is connected, by means of a wire, with the silver plate of one of Mr Smee's batteries. "A piece of copper," says Mr Smee, "of the same size as the plate, should then be connected to the zinc, when both the copper plate and the piece of zinc are to be placed in a solution of sulphate of copper. Immediately copper will be reduced from the solution on the negative plate, and copper from the etching plate will be dissolved to keep up the strength of the solution. Whatever is favourable to the increase of electricity causes the copper to be more quickly acted upon, and whatever diminishes the galvanic current retards the solution of the metal; so that the nearer the etching plate, forming the positive pole, and the piece of copper, forming the negative, are approximated, the more rapid will be the action. In the same way the intensity of the battery also affects the rate at which the plate is bitten in. The negative plate of copper, however, should not exceed in size the copper plate on which the etching is executed, or else there is a risk of some of the lines being more deeply bitten in; and, in like manner, if any considerable part of the plate has a great deficiency of lines, compared with other parts, that part must be stopped out rather before the other, to ensure a uniformity of depth, or else the negative copper opposite the part must be so bent, that it is at a greater distance. The advantages of galvanism for etching are, the absence of poisonous nitrous fumes, which are evolved in the ordinary process; the greater uniformity of action which takes place than when acids are used, and that the rapidity of biting may be regulated to the greatest nicety. The lines may be made of any depth, and are sharper and clearer than when acid is used; and lastly, no bubbles are evolved, which the engraver well knows are apt to tear up the ground, or to cause unequal action."[1]

Voltaic gilding and plating.

4. *Voltaic Gilding and Plating.* We owe the art of gilding upon *silver* and *brass*, by electricity, to M. de La-rive, who was led to it by witnessing the dreadful effects which are produced at Geneva by the use of mercury in gilding. Gold, platinum, palladium, silver, copper, and carbon, when their surfaces are smooth and chemically clean, and freed from adhering air, may be gilt by means of a feeble voltaic current which deposits the gold from a weak nitro-muriate solution of that metal, and in this way a coating of any thickness can be obtained. By a similar process, metals may be platinated or palladinated by using the nitro-muriate solution of those metals. Metals may, in like manner, be covered with nickel by means of its nitrate.

By similar means fruit, vegetables, leaves, seeds may be coated with copper; and crystallised copper may be deposited on wicker work, baskets, &c., after they are blackleaded, or upon articles of earthenware. Mr Smee has succeeded in coating copper with almost every other metal; but for an account of De Larive's and Mr Smee's processes we must refer to the *Bibliotheque Universelle*, April 1840, the *Comptes Rendus*, &c., 1840, No. 14, p. 578, and to the work of Mr Smee, already quoted, book iii.

PART II.—ON ELECTRO-MAGNETISM.

Electro-magnetism.

Various insulated facts and experiments, observed and made by Franklin, Van Marum, Cavallo, Ritter, Mojon, and Maschmann, led to the belief that electricity produced magnetical effects; and this opinion was strengthened by the magnetical changes which had been repeatedly observed in compass needles struck by lightning. It was not, however, till 1820, that electro-magnetism was discovered by Professor H. C. Oersted of Copenhagen. In the month of July of that year, after obtaining several feeble magnetical effects from wires conducting the galvanic current, he at last succeeded, by using larger wires, in establishing the

Oersted.

---

[1] Smee's Electro-Metallurgy, p. 138, 139.

Electro-magnetism.

fundamental law, that *the magnetical effect of the electrical current* has a circular *motion round the current.*

Ampere.

Soon after this important discovery was made, M. Ampere established a second fundamental law of electro-magnetism, that the two conducting wires from the poles of the battery, when conveniently suspended, *attract each other when they transmit electrical currents moving in the same direction, and repel each other when the currents which they transmit have opposite directions.*

Arago.

On the 25th September 1820, M. Arago communicated to the French Institute the important discovery, that the electrical current possesses, in a very high degree, the power of developing magnetism in iron and steel. Sir H. Davy communicated a similar fact to Dr Wollaston on the 12th November 1820, and Dr Seebeck laid before the Royal Academy of Berlin a series of experiments on the same subject. M. Savary of Paris has more recently found that steel needles, placed at different but small distances from a wire conveying an electrical discharge, are not all magnetised in the same direction.

Seebeck.

Savary.

Thermo-electricity.

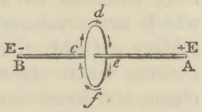
The most important addition to voltaic electricity, since the discovery of Oersted, is that of Dr Seebeck, who found that electro-magnetic currents can be produced by heat alone, a subject which will be treated in a separate chapter on *Thermo-electricity.*

Fundamental experiments in electro-magnetism.

When we join the two poles of a galvanic battery by a metallic wire, this wire is called the *conductor*, or the *uniting wire*, and the galvanic circle is said to be *closed* when this wire is single and unbroken, or when it consists of two wires in contact. When these two wires are not in contact, the circuit is said to be *open*, in which case the wires have no action upon magnetic needles.

Let A B, fig. 50, be the conducting wire of a closed galvanic circuit, along which electricity is carried from A to B, A being the *positive* end, and B the *negative* end; then, if a delicate magnetic needle is suspended near A B, its direction is changed in the following manner:

Fig. 50.



1. When the needle is *above* the wire, its north pole will go from the observer as at *d*, in the upper part of the ellipse, *c d e f*, fig. 50.

2. When the needle is *below* the wire, its north pole will approach the observer, as at *f* in the lower part of the ellipse.

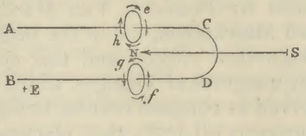
3. When the needle is in the same horizontal plane as the wire, and stands between the observer and the wire, its north pole is *elevated*, as at *c*.

4. When the needle is in the same plane, but on the other side of the conductor, its north end is *depressed*, as at *e*.

Hence, it appears, that the direction of the magnetic current is *c d e f*, when the electrical current is in the direction A B.

If the uniting wire is bent into parallel directions, as in fig. 51, the two exterior surfaces of the branches AC, BD, will exercise similar actions on a needle NS, and so will the two interior surfaces, the actions at *e* and *f* being similar, and also those at *g* and *h*.

Fig. 51.

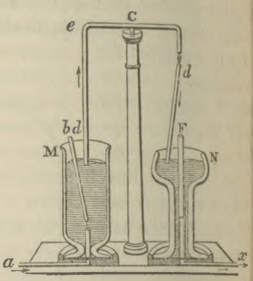


Revolving magnetism

From these experiments, Professor Oersted concluded, *that the magnetical action of the electric current describes circles* round the conductor, and hence he gave the name of *revolving magnetism* to this magnetical action.

This action of *revolving magnetism* was at first opposed by Professor Schweigger, on the ground that if it were true, a magnet might be made to revolve round the uniting wire. Dr Wollaston drew the same conclusion, but for the purpose of producing such a revolution. Before he had effected his purpose, however, Dr Faraday went a step farther, and found experimentally not only *that a magnet could be made to revolve round the uniting wire, but that a moveable uniting wire might be made to revolve round a magnet.* An apparatus for exhibiting these remarkable properties is shewn in fig. 52. A wire *a*, from the voltaic battery, passes into the glass vessel M, through a hole in its bottom, so as to communicate with mercury contained in the vessel. The lower end of a small magnet *b*, of the form of a cylinder, is fixed by a thread to the bottom of the vessel, so that it floats almost vertically in the mercury. A wire C*ed*, communicating with the other en of the battery, by means of the brass pillar C, dips wit its lower end *d* into the mercury in M; and as soon as th voltaic current is established in the direction of the arrows, or *ade*C, the pole *b* of the magnet will revolve roun the fixed conductor *de*C.

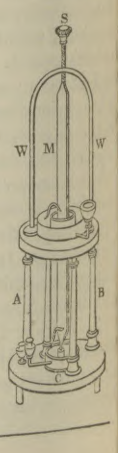
Fig. 52.



The revolution of the conductor round a magnet is exhibited in the same figure, where N is a glass vessel containing mercury, and having a small cylindrical magnet F fixed to its bottom, and projecting a little above the surface of the mercury. The wire *d*, being attached by a hook to the horizontal arm C, will commence its revolutions round, as soon as the voltaic current passes in the directio of the arrows, or *x*F, *d*C. If we make the current pass i the direction *ade*CF*x*, from the zinc to the platinum en of the battery, both the above revolutions will go on simultaneously. When the current was made to pass in th opposite direction, the direction of the rotation was likewise changed.

The rotation of a magnet round its own axis was firs effected by M. Ampere. The magnet was made to floa vertically in mercury, by a platina weight at its lower end. When the electrical current descended through the uppe half which stood above the mercury, it was carried off b the mercury without entering the other half of the magnet. Had a positive current entered the other half, after passing through the first half, it would have tended to make the upper pole revolve from left to right, and the under pole from right to left, and these contrary forces would have balanced each other; but when it is prevented from entering the lower half, the positive current produces a rotation in the magnet from left to right. Mr Watkins[1] has constructed the apparatus in fig. 53, for shewing this experiment in a better way. A flat bar magnet M is supported vertically by the bent wire WSW, fixed to the stand AB. The lower end of the magnet, which is pointed, rests in an agate cup C, while its upper end is a pivot, turning in a hole in the screw S. At the centre and lower end of the magnet are circular grooves containing mer-

Fig. 53.



---

[1] Popular Sketch of Electro-Magnetism.

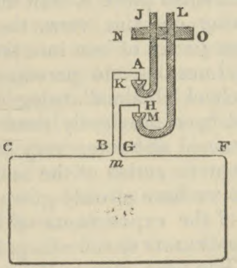
y, into which dip small bent and pointed wires, fixed the magnet, as seen in the figure. When the voltaic cuit is completed in the usual manner, the current ses only through the lower half of the magnet, and ng a moveable part of the circuit, it turns round on two pivots with a velocity depending on the strength the magnet, the power of the battery employed, and the edom from friction at the pivots. A current from another tery might be passed from the top of the magnet to centre, which, by producing a rotation in the same di- ction, would increase the velocity of revolution.

Upon the same principles, a conductor may be made to volve round its axis. An instrument for shewing this s invented by Professor Barlow, and which has been im- oved by Mr Watkins, by applying it to the horse-shoe gnet.[1]

The rotation of liquid conductors may likewise, as Sir Davy has shewn, be produced by the pole of a magnet. mercury is placed in a shallow dish, between the two les of a battery, a magnet placed either above or below mercury, will cause the mercury to revolve round the ints from which the currents issue. The rotation of the me produced by the passage of a powerful voltaic charge tween two charcoal points, arises from the same cause. ofessor Daniell gives the following pleasing method of shewing this effect. He makes a powerful horse-shoe magnet part the conducting wire of a constant battery of a moderate mber of cells; the flame which may then be drawn from e of its poles will revolve in one direction, while that m the other will revolve in the opposite direction.[2]

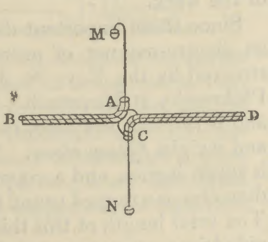
Soon after the discovery of electro-magnetism, M. Am- re made the important discovery, that the conductors tract each other when they are transmitting electrical rrents having the same direction, but repel each other hen the currents have opposite directions. This may be oved experimentally by the paratus in fig. 54, invented M. Ampere. It consists a bent wire, ABCDEFGH, e parts of which at B and G, e kept insulated by a non- nducting substance *m*, to hich they are tied. The tremities A, H, with steel ints dip into iron cups of ercury, K, M, at the ends of e brass wires, JK, LM, fixed to a piece of wood, NO. hen the electric current en- rs at J, passes along the conductor ABCDE, &c., and sues at L, the conductor is put in motion by means a magnet. When the south pole of a magnet is di- cted against the side BCD, it will repel the conductor, ut will attract it when directed against the opposite side.

Fig. 54.



The conductor in the above apparatus may also be oved by the earth's magnetism. For this purpose the ane, CDEF, must stand per- endicularly to the magnetic eridian. When the current nters at A, the vertical part E will be placed towards the est, but if the current enters H, the part FE will be laced towards the east.

Fig. 55.



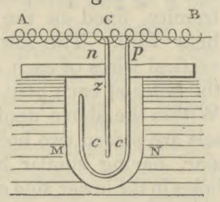
Ampere's electro-dynamic ylinder is shewn in fig. 55, here M is the extremity of a ire, with a steel point rest- ng in a cup of mercury. The wire, after descending to A, passes horizontally through a glass tube AB, and is then wrapped round it to form a helix or spiral, returning to A. It then passes to C, where it is wrapped in a similar manner round the glass tube CD; and when it reaches the end D, it returns through the tube to C, when it descends vertically with its steel point into another mercury cup N. This instrument is a complete imitation of a magnetic cylinder, and, while an electric current is passing through it, it possesses all the properties of a magnet, and may in every case be substituted for one.

Ampere's electro-dynamic cylinders.

Marsh's improvement.

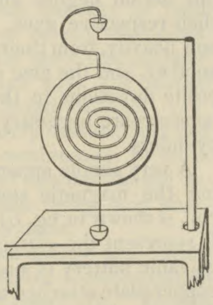
Another electro-dynamic cylinder, invented by Ampere, and improved by Mr Marsh, is shewn in fig. 56. It consists of a coil or helix of wire AB, the ends of which return along its axis to its middle point C, and are there fixed to the wires, *n*, *p*, of a small voltaic battery MN, which consists of a single plate of zinc *z*, surrounded by a plate of copper *cc*, and floating in a basin of diluted acid, in which it can freely move. This spiral ACB, will place itself in the magnetic meridian, when acted upon by the magnetism of the earth, and will likewise yield to the action of another magnet placed near either of its poles.

Fig. 56.



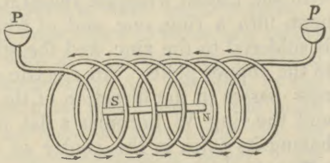
Various forms have been given to these electro-dynamic cylinders. In some the coils all lie in one plane, as in Fig. 57, where one face of the coil has north, and the other south polarity, the magnetic poles being as it were situated in the centre of each disc.

Fig. 57.



When the helix is constructed, as in fig. 58, its power is so great, that a small steel bar SN, placed within it, and supported perpendicularly, will, as soon as the connection is made with the voltaic battery, by means of the mercury cups P, *p*, start up, and place itself in the air, where, like Mahomet's coffin, it will remain suspended without any visible cause, and in opposition to the power of gravitation.

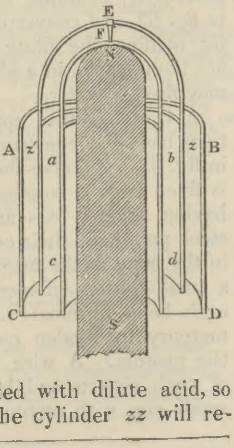
Fig. 58.



Ampere's revolving battery.

We owe also to M. Ampere the very interesting apparatus of a small voltaic battery made to revolve round a magnet. This is shewn in fig. 59, where ABCD, *abcd* exhibits a section of two cylinders of copper soldered to a copper bottom, so as to hold a fluid. This double cylindrical vessel is suspended by a bent wire *a*F*b* (having a cavity at F,) upon the north pole N of a vertical magnet NS. A light cylinder of zinc *zz* is also suspended by a bent wire *z*E*z*, and a steel pivot at E upon the same pole N of the magnet. The cylinder *zz* can therefore revolve upon this pivot. When the cylinder ABD*dbac*CA, is filled with dilute acid, so as to constitute a small battery, the cylinder *zz* will re-

Fig. 59.



---

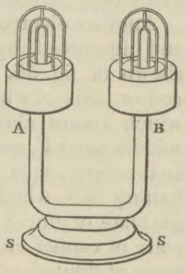
[1] Popular Sketch of Electro-Magnetism.

[2] Introduction to Chemical Philosophy, § 815.

volve from left to right when N is the north end or south pole, and from right to left when N is the south end or north pole. Owing to the attraction of the fluid, the cylinder of zinc is often drawn to one side, and prevented from moving; but this may be avoided by making the space A*c* sufficiently wide. Mr Watkins has ingeniously applied this contrivance to the poles of a horse-shoe magnet, as in fig. 60. It consists of a horse-shoe magnet AB, fixed to a stand SS. Above each pole is suspended a double cylindrical copper vessel, with a bent metallic wire fixed to the top of the inner cylinder, and a vertical wire pointed at each extremity, fixed in the middle of the bent wire. The lower ends of the vertical wires of each cylinder rest in the holes at each pole of the magnet. Within the above double copper vessels are placed two hollow cylinders of zinc, having similar bent wires with holes in the lower side of each, in which holes the upper ends of the vertical wires are inserted. When the copper cylinder is filled with dilute acid, the voltaic action begins, all the four cylinders revolving round their respective axes. The copper cylinders turn slowly and heavily, from their weight, in opposite directions to one another, and the zinc cylinders, with great velocity, in opposite directions to the copper ones. Very delicate suspensions are necessary to ensure the rotation of the copper cylinders.

Mr Watkin's improvement upon it.

Fig. 60.



Delarive's apparatus.

A very simple apparatus for showing the magnetic state of a single coil, is shown in fig. 61, where Z and C represent the elements of a small galvanic battery of one zinc and one copper plate attached to a cork which floats on dilute acid. Each plate is half an inch wide, and two inches long. A piece of copper wire W, with silk thread wrapped 'round it, is bent into a ring, one end of which is soldered to the zinc, and the other to the copper plate. An electric current now passes in the direction of the arrow, and the ring W becomes a flat magnet, having its poles in the centre of its two surfaces, the one being north and the other south. This floating magnet will, when acted upon by a real magnet, exhibit the usual magnetic attractions and repulsions. Mr Marsh has improved this apparatus by doubling the copper plate, as in fig. 62, and converting it into a vessel for holding the dilute acid. The plates are then placed in a glass cylinder which may float in water.

Marsh's improvement upon it.

Fig. 61.

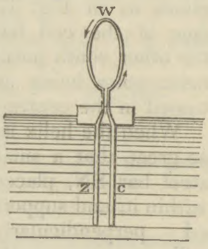


Fig. 62.

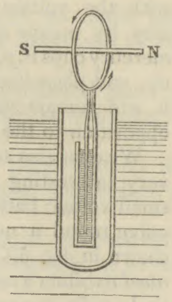
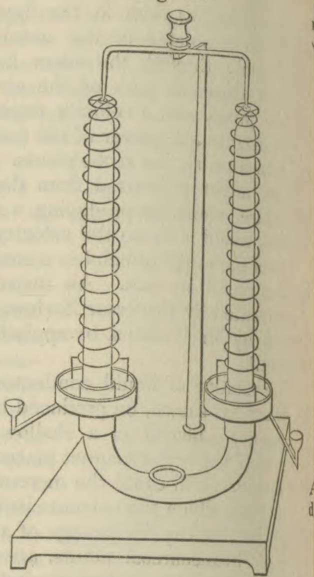


Mr Watkins' revolving helices.

A very beautiful apparatus for exhibiting helical rotations has been constructed by Mr Watkins, and is shown in fig. 63. A horse-shoe magnet, with its poles uppermost, is fixed upon a wooden box S. Two helices of copper, having slender bars across their summit, with needle or steel points in their centre, move in conical holes drilled in the poles of the magnet, with small platina cups to hold a small portion of mercury. The lower extremities of each helix terminate in steel points, which dip into the mercury in wooden cups below, screwed to the legs of the magnet. A wire likewise goes from the lower end of each cistern, and being bent upwards, terminates in a small cup with mercury. The brass rod R, fixed to the stand, carries a forked piece MN, the ends of which are two points which dip in the mercury in the platina cups. On the top of the coil, another mercury cup is placed on the fork MN; and when the voltaic current is made to pass through the apparatus, the helical coils will revolve rapidly in opposite directions, the directions changing with the disposition of the wires which connect them with the voltaic battery.

Fig. 63.



We have already mentioned the fine discovery of M. Arago, of the power of electrical currents to develope magnetism in iron and steel. M. Arago found that the uniting wire of a powerful voltaic battery attracts iron filings often with such force as to form a coating round the wire ten or twelve times thicker than itself. This attraction, as he found, did not originate in any magnetism previously possessed by the iron filings, which he ascertained would not adhere to iron; and that it was not a case of common electrical attraction, was evident from the fact that copper and brass filings were not attracted by the uniting wire. M. Arago likewise found, that the iron filings began to rise before they came in contact with the uniting wire, and hence he drew the conclusion, that the electric current converted each small piece of iron into a temporary magnet. In following out this view, the French philosopher converted large pieces of iron into temporary magnets, and also small steel needles into permanent ones. Sir H. Davy and Dr Seebeck obtained analogous results without knowing what had been previously done in France. M. Savary of Paris obtained also some very important results relative to the magnetic action of the uniting wires at different distances, but we have already given a brief account of them, as well as of the experiments of Professor Erman, in our article, ELECTRICITY, vol. viii. p. 574.

The next step in the progress of discovery, was that of making magnets of extraordinary power by means of a voltaic battery. This seems to have been first accomplished by Professor Moll of Utrecht and Professor Henry of Princetown College, who was able to lift thousands of pounds' weight by his apparatus, but as we have already given a full account of the construction of such magnets, and of the experiments of M. Quetelet of Brussels, and Mr Watkins of London, in our article MAGNETISM, in Sect. xiii. p. 761, vol. viii., we must refer our readers to that part of the work.

Since these important discoveries, however, were made, an electro-magnet of extraordinary power has been constructed by the Rev. N. J. Callan,[1] Professor of Natural Philosophy at Maynooth. It has the form of a horse-shoe, and is *thirteen feet long, two and a-half inches* in diameter, and weighs *fifteen stone*. The distance between its poles is seven inches, and a copper wire one-sixth of an inch in diameter, is wrapped round the bar from one pole to the other. The total length of this thick wire is 490 feet, but it is divided into seven parts, each 70 feet in length. A copper re, about the fortieth of an inch in diameter, is soldered one of the thick wires, about a foot from one of its ex- mities, and is wrapped round the horse-shoe bar in the ne direction as the thick wire, and in one continuous he- . When the opposite ends of the seven thick wires are nnected with the opposite poles of a voltaic battery, the rse-shoe bar is converted into a magnet of extraordinary wer, and when the battery communication is broken, an ctric current of singular intensity is established in the ig coil of small wire. The armature or keeper of Mr llan's magnet was a horse-shoe bar of iron 20 inches long, o and a-half in diameter, and weighing 28 lbs. Its poles re seven inches apart, and the apex of the arch seven hes high. Such was the power of the magnet that it was nd impossible to separate the keeper from it by any force ing in a direction perpendicular to the touching surfaces. e calorimotor, consisting of a single pair of plates, with square feet of copper, and 16 of zinc, was found by Mr ad more effective in exciting the magnetism than a ollaston battery of 100 double pairs highly excited. hen the connexion was broken between the battery and charcoal points fixed to the thick wires, the succession sparks formed a continued blaze of brilliant light, and en a succession of sparks was sent rapidly through a ge fowl, they produced instant death.

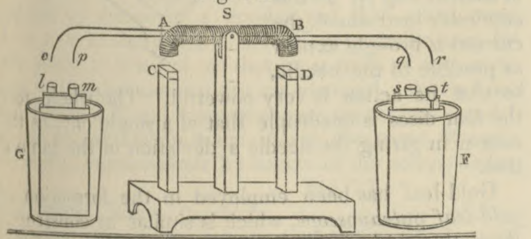
---

[1] See Sturgeon's Annals of Chemistry, &c., July 1837.

The idea of applying the powerful agency thus deve- ped in a bar of iron, as a mechanical power, naturally ggested itself; but there is reason to believe that Mr omas Davenport of Brandon, in the county of Rutland, d state of Vermont, was the first person who thought of plying it in producing rotatory motion. This uneducat- individual, by trade a blacksmith, having, in 1833, acci- ntally seen one of Professor Henry's electro-magnets, rchased it with the idea of employing it as a mechanical wer. In July 1834, he is said to have constructed a vol- c engine; and on the 16th March 1837, he took to New- ven two machines; one a *rotatory machine, composed of volving electro-magnets, with fixed permanent magnets;* d the other, a *rotatory machine, composed entirely of elec- -magnets in its fixed and revolving members,* which being olly made of soft iron, may be magnetised in an instant by ery small battery.[1] Professor Henry,[2] however, had pre- usly, and so early as 1831, produced a reciprocating mo- n by magnetic attraction and repulsion, aided by electro- gnetic action; and as the contrivance seems to have en overlooked in this country, we shall lay before our aders his own drawing and description of it.

In Fig. 64, AB is an electro-magnet of soft iron, about even inches long, and moveable on an axis at the centre Its two extremities, when placed in a horizontal line, about one inch from the north poles of the upright gnets C and D. G and F are two large tumblers con- ing dilute acid, in each of which is immersed a plate zinc, surrounded with copper. *l, m s, t,* are four brass nbles soldered to the zinc and copper of the batteries, filled with mercury.

Fig. 64.



Electro-magnetism.

"The electro-magnet AB is wound with three strands of copper bell wire, each about twenty-five feet long. The similar ends of these are twisted together, so as to form two stiff wires, which project beyond the extremity B, and dip into the thimbles *s, t.*

"To the wires *q, r,* two other wires are soldered, so as to project in an opposite direction, and dip into the thimbles *l, m.* The wires of the electro-magnet have thus, as it were, four projecting ends; and by inspecting the figure it will be seen that the extremity *m,* which dips into the cup attached to the copper of the battery in G, corresponds to the extremity *r* connecting with the zinc F.

"When the batteries are in action, if the end B is depressed until *q r* dips into the cups *s, t,* AB instantly becomes a powerful magnet, having its north pole at B. This of course is repelled by the north pole D, while at the same time it is attracted by C. The position is consequently changed, and *o p* comes in contact with the mercury in *l, m.* As soon as the communication is formed, the poles are reversed, and the position again changed. If the tumblers be filled with strong dilute acid, the motion is at first very rapid and powerful, but it soon almost entirely ceases. By partially filling the tumblers with weak acid, and occasionally adding a small quantity of fresh acid, a uniform motion, at the rate of seventy-five vibrations in a minute, has been kept up for more than an hour. With a large battery, and very weak acid, the motion might be continued for an indefinite length of time.

"The motion here described is entirely distinct from that produced by the electro-magnetic combination of wires and magnets. It results directly from the mechanical action of ordinary magnetism—galvanism being only introduced for the purpose of changing the poles."

Professor Green, to whom Professor Henry first exhibited this machine in motion, recommended the substitution of electro-magnets for the two vertical ones C, D. Though Professor Henry described this apparatus as a toy, yet he distinctly states, that in the progress of discovery, the same principle, or some modification of it on a more extended scale, might hereafter be applied to some useful purpose.

Rev. Mr M'Gauley's electro-magnetic power.

These contrivances have been followed by several others of great ingenuity. The Rev. J. W. Macgauley exhibited a working model of an electro-magnetic machine, to the British Association at Dublin in 1835; and in the sixth report of the Association he mentions his having "in his possession a machine of not inconsiderable power." Mr Sturgeon of Woolwich mentions that he had a galvanic machine in use on his premises, for pumping water, and for other mechanical purposes.[3] Mr Jacobi has some time ago employed electro-magnetic machinery for impelling a boat on the Neva at St Petersburg; and Mr Davidson of Aberdeen has made a similar application to a turning lathe.

Schweigger's electro-magnetic multiplier.

A series of beautiful instruments, of great practical value, have been invented for increasing minute voltaic effects, by electro-magnetic action. The first of these was constructed by Professor Schweigger of Halle, immediately after the discovery of electro-magnetism. It is exhibited in fig. 65 where a magnetic needle SN, is placed or suspended within several bendings of the uniting wires ABCDE. Now, as each of the branches of this wire acts upon one of the poles of the needle in the same direction, the effect will be *quadrupled;* and hence the direction of the needle becomes a means of measuring any minute voltaic effects produced in the uniting

Fig. 65.

[3] Report on, vol. v. p. 24.

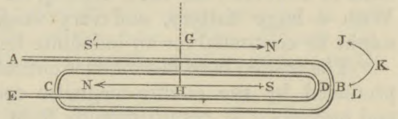
Professor Oersted's improvement upon it.

wires. The power of multiplication does not, as Dr Seebeck proved in 1820, increase with the number of windings in the uniting wire, as the resistance to transmission increases with the length of the wire, thus diminishing the conducting power of the wire. Professor Orested improved the multiplier[1] by adding a bent magnet, as shewn at JKL, fig. 66, which can be placed so as to repel the nearest end of the needle, or index, or to attract it. In the position in the figure the first of these effects is produced; but by turning the angle of the bent magnet towards the needle, the second effect is produced. By causing the pillar which carries this magnet to approach to, or recede from the needle, the directive power of the needle may be made scarcely sensible. In this state the instrument will shew the difference in the voltaic effects produced by two pieces of metal, which differ only by $\frac{1}{10}$th of alloy when a powerful liquid is used. Professor Cumming, we believe, first suggested the idea of neutralizing the directive force of the needle, arising from the earth's magnetism, which he did by placing a magnetized needle immediately beneath the moveable or index needle.[2]

Nobili's multiplier.

M. Nobili has improved this instrument by using two needles, as in fig. 66; but he fixed the neutralizing needle S′N′, to the moveable one NS, placing the one above the other, with their poles reversed. The two needles are fixed in a piece of straw GH, and suspended by a silk fibre at G. The needles were twenty-two lines long, three wide, and one-fourth thick, and GH was five lines. The wire was a copper one, one-fifth of a line in diameter, and thirty feet long, and covered with silk. It made seventy-two evolutions round the frame.

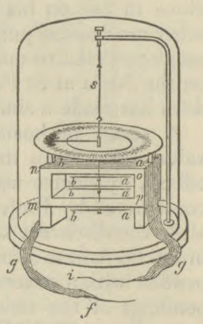
Fig. 66.



Lebaillif's multiplier.

M. Lebaillif has extended this principle by using four needles in place of two, each pair being exactly the same as in fig. 66, the one being brought near the upper surface of the coil, and the other near the under surface. In this instrument the increased weight of the needles may compensate any additional sensibility possessed by the approximation of the needles to the sides of the coil. The instrument is shewn in fig. 67, where *ab*, *ab* are the four needles, *mnop* the square bobbin, around which the wires are coiled, one or two feet of their length at each end being left free, as at *gi*, *gf*, that the electric current may enter at the one, and issue from the other. Instead of a single wire 300 feet long, M. Lebaillif employs *five* parallel ones, each end of which is stripped of the silk, and united by strong pressure into a bundle. The electric current thus divided into five parts, flows in five channels, which, according to M. Pouillet, transmit a proportionally larger quantity of electricity, while the diminished intensity produced by transmission through a great length of wire, is avoided.[3]

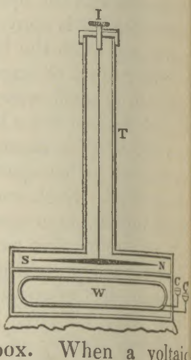
Fig. 67.



Dr Ritchie's torsion galvanometer.

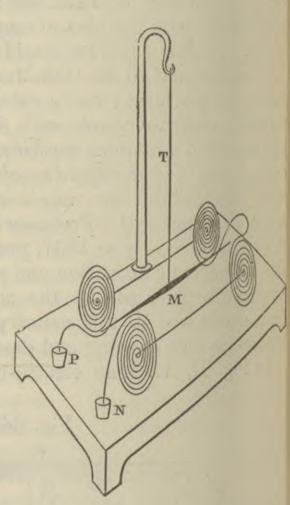
A torsion galvanometer invented by Dr Ritchie,[4] is shewn in fig. 68. Having covered a fine copper wire with a thin coat of sealing wax, he rolls it about a heated cylinder, an inch or two in diameter, ten, twenty, or any number of times. The opposite sides of the circular coil are then pressed together, till they become parallel, and about one or one and a half inches long. The coil W is then fixed on a proper sole, and the ends of the wires connected with two metallic mercury cups C, C. A graduated disc of paper is then placed horizontally on the upper half of the coil, having a black line drawn through its centre, parallel with the middle line of the coil. A small magnet SN, made of a common sewing needle, is then fixed to the lower end of a fine glass thread, while the upper end is securely fixed with sealing wax, in the centre of a moveable index I, as in the torsion balance. This is inclosed in a glass tube T, fitted into a disc of thick plate glass, which forms the upper surface of the box. When a voltaic current passes through the coil W, the needle SN is deflected. The glass thread is then twisted by turning the index I, till the needle is brought back to its former position, and the number of degrees of torsion will be an accurate measure of the quantity of electricity, whose deflective power over the needle is exactly balanced by the torsion of the glass fibre.

Fig. 68.



A very ingenious galvanoscope, for ascertaining merely the existence and direction of an electric current, is described in the Library of Useful Knowledge.[5] It is shewn in fig. 69, where M is the needle, T the suspending fibre, placed between four vertical spiral coils, the centres of which are brought very near the poles of the needle. The same voltaic current is made to circulate through all the four spirals, which have their turns such as to produce repulsion of the contiguous pole on the one side, and attraction of the same pole on the other side. The wire of the four spiral discs proceeds from the mercury cup P, and terminates in another cup N. In this admirable instrument, the current is brought as near as possible to the needle, so that its action is very powerful. The whole force of the four discs is quadruple that of a single one, as they all concur in giving the needle a deviation in the same direction.

Fig. 69.



Gold-leaf has been employed in the formation of the *gold-leaf galvanoscope*, which is similar in construction to Bennet's gold-leaf electrometer. The strength of the current is indicated by the curvature of the strip of gold-leaf *f h*, fig. 70, which is held loosely by forceps at *f* and *h*, each forceps terminating in a mercury cup, the one, P, being above, and the other, N, below. The gold-leaf is enclosed in a glass case, the middle of which is placed equidistant between the poles M, *m*, of a horse-shoe magnet. When the electric current passes through the gold-l f, the leaf is bent, or *attracted* and *repelled* laterally t the poles of the magnet, according as the current *ends* or *descends*, the broad surface of the leaf becoming c*vex* towards the magnet in the c case, and *concave* in the other. the degree of curvature is easily a ertained, Dr Roget considers this i trument as affording "the most d icate test possible of the existence a l direction of a weak voltaic cur- r t."[1]

---

[1] For a perspective drawing on a large scale, of this instrument, see Edinburgh Encyclopædia, art. Thermo-Electricity, plate 522, fig. 11.

[4] Phil. Trans. 1830. p. 218.

[5] Art. *Electro-magnetism*, part ii. chap. viii. p. 44, fig. 82.

We shall now conclude this part o the article with an account of a ery ingenious contrivance of Am- p e's for quickly altering the direc- t of the electric current in vol- t batteries. Two grooves R, I fig. 71, are made in the t le TT, some lines in depth, a l also four similar cavitics *vv′*, *tt′*, c nmunicating diagonally by means c the plates of copper *ll*, *mm*, v ich are kept separate at t ir crossing by a non-con- c cting substance. Mercury i hen placed in the grooves a l cavities, after they have b n varnished with mastic. I he positive wire of a bat- t y is immersed in the groove l and the negative one in t groove R′, the current will n flow until a metallic c nmunication is made be- t en each of the grooves, and o of the cavities. To do t , *b*, *b′* are two p es, fig. 72, for t nsmitting the c rent; the plate *b* nay become po- s ve or negative, a ording as the c ity R communi- c s with *t*, and R′ with *t′*, or when R communicates with *v* and R′ with *v′*. I the first case, the current follows the direction R*t*, *bb′*, *t′* , in the second it goes from R to *v*, then traverses the p e *ll′*, and afterwards goes from *b′* into *bt*, and from *v′* i R. Now, these communications may be easily made or i errupted, by means of a wooden rod BB′, which turns r nd its axis in the holes *o*, *o′*. Four metallic arcs *bb′*, *a* are fitted to this rod, so that by merely raising or de- p ssing it, the communications are changed. When *b* and *b* re depressed, R and *v* communicate through *rbc*, and R a *v′* by *r′b′c′*, and when *d* and *d′* are depressed, R and *t*, a R′ and *t′* communicate by means of the corresponding a s.[2]

Fig. 70.

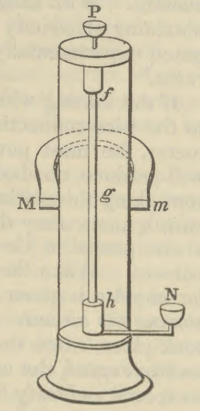

Fig. 71.

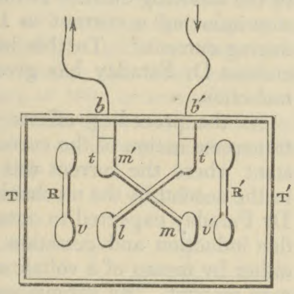

Fig. 72.

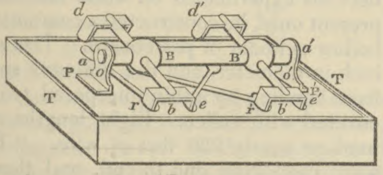
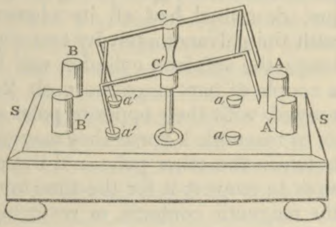


Mr Edward Clarke h improved this in- s ument, and, we b ieve, given it the n ne of electripeter. I s shown in fig. 73, w ere *a*,*a*,*a′*,*a′* are four m rcury cups, commu- c ng with wires be- n th the stand SS′. I ge mercury cups A, A′, B, B′, are similarly constructed for conveying the current from the battery to a machine to be set in motion. The wires CC′ are moveable about a horizontal axis. Suppose them to be in the position in the figure, and that the current is passing from A to B, and back again, from any apparatus from B′ to A, then, by merely pressing the other ends of the wires CC′ into their respective cups *a*,*a*, the direction of the current will be immediately changed, and it will pass from A beneath the stand, to B′, and back from B to A. By retaining the wires horizontally which keep their ends out of the cups, the passage of the current will be stopped.[3]

Fig. 73



Applications of electro-magnetism.

Among the applications of Electro-magnetism, two of the most interesting are the *Electro-magnetic Telegraph*, and the *Electro-magnetic Clock*, invented by Professor Wheatstone, of King's College, London.

Wheatstone's Electro-magnetic Telegraph.

Wheatstone's electro-magnetic telegraph.

Although the idea of conveying signals along wires by means of electric currents, must have occurred to many persons, yet the value and success of the invention must depend on the principles and methods by which that idea is carried into effect. Professor Wheatstone and Mr Cook have taken out a patent for this invention, and, in March 1840, it was in practical operation on the Great Western railway, throughout a distance of 14 miles from Paddington to West Drayton. It is also in operation on Blackwall railway. Professor Wheatstone has recently made an entirely new arrangement for his telegraph, which possesses great advantages over the old one: It is extremely portable; and any child can both read and send the messages with scarcely a minute's instruction. It requires only a single pair of wires, and 30 or 40 letters can be successively sent by it in a minute. The telegraph with its accompanying alarm, is included in a case not larger than that of the smallest table clock. From the utility, simplicity, and cheapness of this new contrivance, we are convinced that its application will not be confined to long telegraphic lines, but will also be extensively employed in public and private establishments.

Wheatstone's Electro-magnetic Clock.

Wheatstone's electro-magnetic clock.

To the same ingenious author we owe one of the most beautiful inventions of modern times, the electro-magnetic clock, the detailed construction of which has not yet been published. The following is a brief abstract of the account of it which was read at the Royal Society on the 26th November 1840.

The object which Professor Wheatstone had in view was *to enable a single clock to indicate exactly the same time in as many different places distant from each other as may be desired.* In an observatory, for example, every apartment may be furnished with a cheap and simple clock, scarcely liable to derangement, and giving the time so accurately, *that it will beat dead seconds audibly with as great precision as the standard astronomical timepiece with which it is connected.* Hence the necessity is avoided, in such scientific establishments, of having several clocks, and of being at the trouble of winding them up and regulating them individually. "In like manner, in public offices and large establishments, one good clock will serve the purpose of indicating the precise time in every part of the building where it may be required, and an accuracy ensured which it would be difficult to obtain by independent clocks, even putting the difference of cost out of consideration. In the electro-magnetic clock, which was exhibited in action in the apartments of the Society, all the parts employed in a clock for maintaining or regulating the power are entirely dispensed with. It consists simply of a

[2] Becquerel, Traité D'Electricité, &c. tom. iii. pp. 9, 10.

Wheatstone's electro-magnetic clock.

face with its second, minute, and hour hands, and of a train of wheels which communicate motion from the action of the second hand to that of the hour hand, in the same manner as in an ordinary clock train; a small electro-magnet is caused to act upon a peculiarly-constructed wheel (scarcely capable of being described without a figure) placed on the second's arbor, in such a manner that whenever the temporary magnetism is either produced or destroyed, the wheel, and consequently the second's hand, advances a sixtieth part of its revolution. It is obvious, then, that if an electric current can be alternately established and arrested, each resumption and cessation lasting for a second, the instrument now described, although unprovided with any internal maintaining or regulating power, would perform all the usual functions of a perfect clock. The manner in which this apparatus is applied to the clocks, so that the movements of the hands of both may be perfectly simultaneous, is the following:—On the axis which carries the scape-wheel of the primary clock a small disc of brass is fixed, which is first divided on its circumference into sixty equal parts; each alternate division is then cut out and filled with a piece of wood, so that the circumference consists of thirty regular alternations of wood and metal. An extremely light brass spring, which is screwed to a block of ivory or hard wood, and which has no connection with the metallic parts of the clock, rests by its free end on the circumference of the disc. A copper wire is fastened to the fixed end of the spring, and proceeds to one end of the wire of the electro-magnet; while another wire attached to the clock-frame, is continued until it joins the other end of that of the same electro-magnet: A constant voltaic battery, consisting of a few elements of very small dimensions, is interposed in any part of the circuit. By this arrangement the circuit is periodically made and broken, in consequence of the spring resting for one second on a metal division, and the next second on a wooden division. The circuit may be extended to any length; and any number of electro-magnetic instruments may be thus brought into sympathetic action with the standard clock. It is only necessary to observe, that the force of the battery and the proportion between the resistances of the electro-magnetic coils, and those of the other parts of the circuit, must, in order to produce the maximum effect with the least expenditure of power, be varied to suit each particular case."

In Professor Wheatstone's paper, of which the above is an abstract, he has pointed out several methods of effecting the same purpose. In one of them he substitutes Dr Faraday's magneto-electric currents, in place of the voltaic battery, and he likewise describes a modification of his clock which will enable it to exercise its controlling power with a weaker electric current than when constructed on the plan above described. Professor Wheatstone has likewise pointed out other most important purposes to which his invention is applicable.

PART III.—MAGNETO-ELECTRICITY.

Magneto-electricity.

In the preceding chapter, we have detailed the leading phenomena produced by electric currents, or electricity in motion, for no magnetic effects are produced by accumulated electricity. We come now to give an account of the new science of magneto-electricity, which we owe to Dr Faraday. Although certain effects of the *induction* [1] of electrical currents had been discovered, it had always appeared to Dr Faraday unlikely that these could be the only effects which induction by currents could produce; and whatever theory of the phenomena might be adopted, it still seemed to him "very extraordinary, that as every electric current was accompanied by a corresponding intensity of magnetic action, at right angles to the current, good conductors of electricity, when placed within the sphere of this action, should not have any current induced through them, or some sensible effect produced equivalent in force to such a current. With these views, and under the expectation of obtaining electricity from ordinary magnetism, he investigated experimentally the inductive effect of electrical currents."

Dr Faraday's researches.

If the uniting wire of a voltaic battery is placed parallel to the wire connecting the two ends of a delicate galvanometer, the most powerful current along the uniting wire will produce no deviation in the needle. But if the current along the uniting wire is stopped, by *breaking the circuit*, a momentary deviation of the needle takes place, as if a wire passed in the same direction as that of the voltaic current. When the needle has become stationary, a similar impulse is given to it in the opposite direction, by *restoring the circuit*. Dr Faraday found that similar effects took place, when the *current along the uniting wire being uninterrupted*, the uniting wire was made to approach or to recede *suddenly* from the wire of the galvanometer, the *approximation* inducing a current in the direction *contrary* to the inducing current in the uniting wire, and the *division* inducing a current in the *same* direction as the inducing current.[2] To this inductive action of the voltaic current Dr Faraday has given the name of *volta-electric induction*.

As the preceding effects were clearly produced by a transverse action of the current, in the first case at the instant where the current was annihilated or generated, and in the second by the mechanical motion of the uniting wire, Dr Faraday expected to obtain similar results, by the sudden induction and cessation of the same magnetic force, either by means of a voltaic current, or by that of a common magnet. By various experimental arrangements, Dr Faraday verified these anticipations; but in order to connect his experiments on volta-electric induction with the present ones, he constructed a combination of helices upon a hollow cylinder of pasteboard. The wire was 1-20th of an inch in diameter, and the different spires were prevented from bending by a thin interposed twine. Each helix was covered with calico. Eight lengths of copper wire were used, or nearly 220 feet of wire. "Four of these helices were connected end to end, and then with the galvanometer; the other intervening four were also connected end to end, and the battery of 100 pairs discharged through them. In this form, the effect on the galvanometer was hardly sensible, though magnets could be made by the induced current. But when a soft iron cylinder, $\frac{7}{8}$ths of an inch thick, and 12 inches long, was introduced into the pasteboard tube, surrounded by the helices, then the induced current affected the galvanometer powerfully. It possessed also the power of making magnets with more energy apparently than when an iron cylinder was used. When the iron cylinder was replaced by an equal cylinder of copper, no effect beyond that of the helices alone was produced." "Similar effects," continues Dr Faraday, "were produced with ordinary magnets. Thus, the hollow helix just described had all its elementary helices connected with the galvanometer, by two copper wires each five feet long; the soft iron cylinder was introduced into its axis; a couple of bar magnets, each 24 inches long, were arranged, with their opposite poles at one end in contact, so as to resemble a horse-shoe magnet, and then contact made between the other poles and the ends of the iron cylinder, so as to convert it for the time into a magnet; by breaking the magnetic contacts, or reversing them, the magnetism of the iron cylinder could be destroyed or reversed at pleasure. Upon making magnetic contact, the needle was deflected; continuing the contact, the needle became indifferent, and resumed its first position: on breaking the contact, it was again deflected, but in the opposite direction to the first effect, and then it again became indifferent. When the magnetic contacts were reversed, the deflections were reversed. When the magnetic contact was made, the deflection was such as to indicate an induced current of electricity in the *opposite* direction to that fitted to form a magnet, having the same polarity as that really produced by contact with the bar magnet."

---

[1] By *induction* Dr Faraday intends to express the power of electrical currents "to induce any particular state upon matter in their immediate neighbourhood otherwise indifferent." *Experimental Researches*, p. 1.

[2] Experimental Researches, p. 5.

But in order to show that it was by the approximation of the magnets that the momentary induced current was excited, Dr Faraday substituted for the soft iron cylinder a cylindrical magnet 8½ inches long, and ¾ths of an inch in diameter. He introduced one end of this magnet into the axis of the helix, and then, the galvanometer needle being stationary, the magnet was *suddenly thrust in*, the needle was then instantly deflected in the same direction as if the magnet had been formed by any of the two preceding processes. "Being left in, the needle resumed its first position, and then the magnet being *withdrawn*, the needle was deflected in the opposite direction. These effects were not great, but by introducing and withdrawing the magnet, so that the impulse each time should be added to those previously communicated to the needle, the latter could be made to vibrate through an arc of 180° or more.[1]"

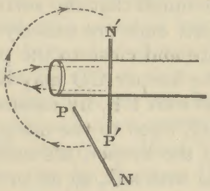

Fig. 74.

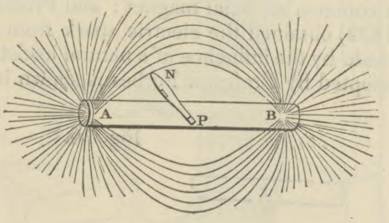
Although the law which governs the evolution of electricity by magneto-electric induction, is very simple, yet Dr Faraday has found it rather difficult to express it, except in reference to diagrams. We shall therefore give it in his own words. "If in fig. 74, PN represent a horizontal wire passing by a marked magnetic pole, so that the direction of its motions shall coincide with the curved line proceeding from below upwards; or if its motion parallel to itself be in a line tangential to the curved line, but in the general direction of the arrows; or if it pass the pole in other directions, but so as to cut the magnetic curves[2] in the same general direction, or on the same side as they would be cut by the wire if moving along the dotted curved line; then the current of electricity in the wire is from P to M. If it be carried in the reverse direction, the electric current will be from N to P. Or if the wire be in the vertical position, as at P′N′, and it be carried in similar directions, coinciding with the dotted horizontal curve, so far as to cut the magnetic curves on the same side with it, the current will be from P′ to N′. If the wire be considered a tangent to the curved surface of the cylindrical magnet, and it be carried round that surface into any other position, or if the magnet itself be revolved on its axis, so as to bring any part opposite to the tangential wire; still, if afterwards the wire be moved in the directions indicated, the current of electricity will be from P to N; or if it be moved in the opposite direction, from N to P; so that as regards the motions of the wire past the pole, they may be reduced to two, directly opposite to each other, one of which produces a current from P to N, and the other from N to P.

"The same holds true of the unmarked pole of the magnet, except that if it be substituted for the one in the figure, then, as the wires are moved in the direction of the arrows, the current of electricity would be from N to P, and when they move in the reverse direction, from P to N.

"Hence the current of electricity which is excited in metal when moving in the neighbourhood of a magnet, depends for its direction altogether upon the relation of the metal to the resultant of magnetic action, or to the magnetic curves, and may be expressed in a popular way, thus: Let AB (fig. 75) represent a cylinder magnet, A being the marked pole, and B the unmarked pole; let PN be a silver knife-blade resting across the magnet, with its edge upward, and with its marked or notched side towards the pole A; then in whatever direction or position this knife be moved edge foremost, either about the marked or the unmarked pole, the current of electricity produced will be from P to N, provided the intersected curves proceeding from A abut upon the notched surface of the knife, and those from B upon the unnotched side. Or, if the knife be moved with its back foremost, the current will be from N to P in every possible position and direction, provided the intersected curves abut on the same surfaces as before. A little model is easily constructed, by using a cylinder of wood for a magnet, a flat piece for the blade, and a piece of thread connecting one end of the cylinder with the other, and passing through a hole in the blade, for the magnetic curves; this readily gives the result of any possible direction.

Fig. 75.



"When the wire under induction is passing by an electro-magnetic pole, as for instance, one end of a copper helix traversed by the electric current the direction of the current in the approaching wire is the same with that of the current in the parts or sides of the spirals nearest to it, and in the receding wire the reverse of that in the parts nearest to it.

"All these results show that the power of inducing electric currents is circumferentially exerted by a magnetic resultant, or axis of power, just as circumferential magnetism is dependent on, and is exhibited by an electric current."[3]

Dr Faraday has made several experiments with the large compound magnet of Dr G. Knight, belonging to the Royal Society, and consisting of 450 bar magnets, each 15 inches long. The electrical effects which it exhibited were very striking. When a soft iron cylinder, 13 inches long, was put through the compound hollow helix, with its ends arranged as two general terminations, and these connected with the galvanometer; then, when the iron cylinder was brought in contact with the two poles of the magnet, so powerful a rush of electricity took place, that the needle whirled round many times in succession. When Dr Faraday brought the helix alone near to or between the poles, the needle was thrown 80°, 90°, or more, from its natural position.

Dr Faraday failed in obtaining evidence of chemical decomposition by the magnet, or any sensation on the tongue, or any effect on a frog, but he afterwards, by an armed loadstone of Professor Daniell's, lifting 30 pounds, not only thought that he perceived a sensation on the tongue, and a flash before the eyes, but was able to produce a very powerful convulsion in the limbs of a frog, every

---

Experimental Researches, p. 11, or Phil. Trans. 1832, p.

By magnetic curves, I mean the lines of magnetic forces, however modified by the juxtaposition of poles, which would be depicted by iron filings, or those to which a very small magnetic needle would form a tangent.

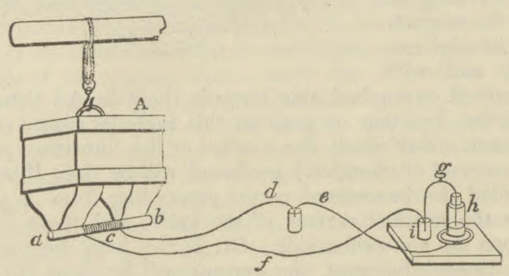
[3] Experimental Researches pp. 32, 34.

time that magnetic contact was made, the convulsive effect increasing with the suddenness with which the contact was broken and restored.

Electric shock from a magnet.

Dr Faraday, as we have now seen, was the first person who obtained, in November 1831, the electric spark from a magnet. The spark which he obtained was got from a soft iron magnet, made by the influence of a voltaic current. Professor Nobili[1] and Antinori afterwards obtained the electric spark from a soft iron magnet, made by the influence of a common artificial magnet; and Professor Forbes (March 1832) obtained the electric spark from a soft iron magnet, made by the influence of a natural loadstone.[2] The method adopted by Professor Forbes is shewn in fig. 76, where A is a suspended natural magnet. A cylindrical keeper or armature, *ab*, has a helix, *c*, coiled round it, about 7½ inches long, and consisting of about 150 feet of copper wire, about 1-20th of an inch in diameter; the helix consisted of four layers in thickness, separated by insulating partitions of cloth and sealing wax. The branch *bde* of the wire terminates in the bottom of the glass tube *h*, containing mercury, with a pure surface. The other branch *f* of the helix communicates by means of the mercury cup *i*, with the iron wire *g*, the fine point of which is brought by the hand into contact with the surface of the mercury in *h*, and is separated from it the instant the keeper *ab* is brought into contact with the poles of the magnet; the spark is then produced in the tube *h*.[5]

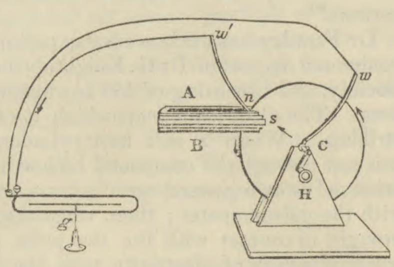
Fig. 76.



Rotatory magneto-electric apparatus.

That the action of magneto-electricity is the converse of that of electro-magnetism, is well shown in the rotatory apparatus in fig. 77. It consists of a copper disc C, revolving round a horizontal axis by means of the handle H. A powerful horse-shoe magnet, AB, is so placed that the edge of the disc C, can revolve between its poles *n*, *s*. Two conducting wires *w*, *w'*, are so placed, that two of their extremities terminate in the mercury cups of a galvanometer *g*, while the other end of the first is kept in perfect metallic contact with the axis, and the other end of the second is in contact with the circumference of the disc at the point between the poles *n* and *s* of the magnet. When this disc revolves from right to left, an electric current proceeding from the centre to the circumference of the disc, is generated in the direction of the curves, and the needle of the galvanometer is deflected. If the disc revolve from left to right, the electric current moves in the opposite direction.

Fig. 77.



For further information on the subject of magneto-electric induction, see Mr Faraday's recent papers in the *Annales de Chimie et de Physique*, tom. li. p. 404, &c., *Lond. and Ed. Phil. Mag.* October and November 1840, vol. xvii. p. 281 and 356, and Dr Golding Bird's *Elements of Natural Philosophy*, Lond. 1839, p. 243.

Description of Magneto-Electric Apparatus.

After Dr Faraday's great discovery of *magneto-electric* and *volta-electric induction*, various machines were constructed for experimental investigation and exhibition. M. Hippolyte Pixii of Paris exhibited to the Academy of Sciences in 1832, his *magneto-electric* machine. A powerful magnet was made to revolve with great rapidity before its keeper or armature, which had round it a coil of copper wire about three thousand feet long. By this means sparks and severe shocks were obtained, a feeble charge was accumulated in a Leyden phial, the gold leaves of an electrometer were made to diverge, and water was decomposed.

A very ingenious and complete machine was exhibited by Mr Saxton, at the meeting of the British Association in June 1833, as shewn in fig. 78. The magnet A is a horse-shoe one of great power, composed of many steel plates, closely applied to each other, or it may be a soft iron electro magnet of the same shape. A keeper, CD, of the purest soft iron, has each of its ends bent into a right angle, and is so mounted that the surfaces of their ends are exactly opposite and close to the poles of the magnet. In this position the keeper CD may be made to revolve round the horizontal axis EF, by means of the wheels C and E, and band GE fixed to the upright pillar B. Round each end, C, D, of the keeper, are coiled two series of copper wires, covered with silk, so as to form compound helices. The ends of these wires, which have the same direction, are joined together, and are likewise connected with a circular disc, revolving with the keeper in a cup of mercury, with which in every position of the disc it is in metallic communication. The other ends of the wires are joined, and passing together without metallic contact through the spindle EF, terminate in a slip of copper, with two opposite points, as at *i*, at right angles to the axis. These points alternately dip into, and rise above the mercury, in another cup, K, which may be connected with the first by means of a copper wire. Now, whenever the ends of the keeper are opposite the poles of the magnet, the keeper becomes a temporary magnet, and it ceases to be so when the line joining them is at right angles to the line joining the two poles. The instantaneous generation and extinction of the magnetic force, which takes an opposite direction in the keeper according as its opposite ends are close to the same poles, and induce corresponding opposite electric currents in the copper wire, provided the circuit is complete by the immersion of the points at *i*. The arrangement of the points at *i* is such, that they just rise from the mercury as the ends of the keeper come opposite to the poles of the magnet; and hence the sudden breach of the circuit makes the current pass in the form of a brilliant spark. If a fine platinum wire, instead of the dipping points, forms the communication between the revolving disc and spindle, it may be kept at a red heat, its light slightly intermitting from the alternation of the currents. If a communication is formed be-

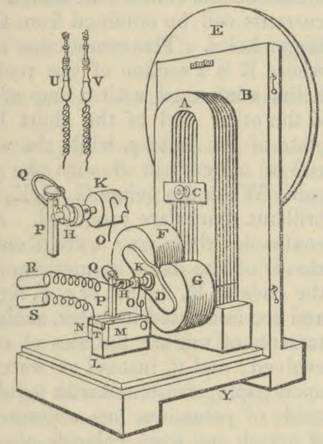
tv en the two cups of mercury by two copper cylinders gr ped in the hands, a strange sort of shock will be experi ced, which is sometimes almost intolerable. Chemical de ompositions are also readily effected, and the amount w be proportioned to the quantity of electricity in circula on.

he magneto-electric machine has been greatly improved b Mr E. M. Clarke, magnetical instrument maker, Lon-d . It is represented in fig. 79, where A is the battery o ent bar magnets rest-in against the vertical b rd B, and by means of a r of brass C, with a b and screw-wheel, the m nets can be drawn fi ly to the board B, or ta n from it. One of th keepers or armatures D s screwed into a brass m drill between the p s of the magnets, and it made to revolve by th multiplying wheel E. T s armature has two c s of fine copper wire 1 0 yards long wrapped r nd its cylinders, the b inning of each coil b ng soldered to the a ature D, from which a projects a brass stem carrying the break piece H, which c be fastened in any required position by a binding screw. ollow brass cylinder K, to which the ends of the coils a soldered, being insulated by means of a piece of hard w d attached to the brass stem. An iron wire spring O p sses at one end against the cylinder K, and is kept in c tact with it by a screw in a brass strap M in the wooden b ck L. A square brass pillar P fits also a square opening i he other brass strap N on the other side of the block L. metallic spring Q rubs gently upon the break piece H, a l is retained in perfect metallic contact with it by a screw i the pillar P, the two straps of brass M, N, are connect- by a piece of copper wire T, and in this state the parts H, Q, P, N are in connexion with the commencement ach coil, and the parts K, O, M with the termination of h coil. The perfect metallic contact thus obtained by spring and break, enables Mr Clarke to dispense entire- with the use of mercury, which is at all times a trouble- ne accompaniment of machinery.

Fig. 79.



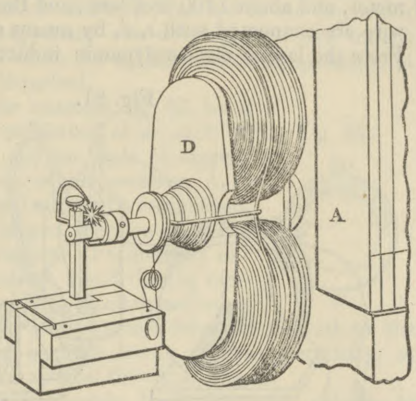
But the great superiority of Mr Clarke's machine arises m his employing two different armatures, and thus being bled to produce the separate effects of quantity and in- sity to the full extent of the power of his battery. ving, in November 1834, tried the effects of coils of wire different thicknesses, he found that the thick copper bell e gave brilliant sparks, but no perceptible shock, while y fine wire gave powerful shocks, but very feeble sparks. means of the *intensity armature*, which is that shewn in 79, the various experiments made with a number of arate galvanic plates may be performed, while the in- se agony produced by its shocks is intolerable: It can, at same time, electrify the most nervous person without asioning the least uneasiness. It decomposes water and neutral salts. It deflects the gold leaves of the electro- pe, charges the Leyden jar; and by an arrangement of es from the mercury box to the battery, the electricity is de visible, passing from the magnetic battery to the ar- ture, and sparks and brilliant scintillations of steel can be ained.

Magneto-Electricity.

Quantity armature.

The *quantity armature* differs greatly from the intensity one, as is shewn in fig. 80, which exhibits the method of producing the spark. The weight of the iron in the cylinders is much greater than in the intensity one, the copper wire is much thicker, and its length is only forty yards. By this armature all the experiments can be made which are usually performed by a single pair of voltaic plates of large surfaces, or by a calorimotor; but it will not do for any of the intensity experiments. It produces such large and brilliant sparks, that a person can read small print from the light it produces. It ignites gunpowder and platina wire, without enclosing the wire in a hermetically sealed glass case. It deflagrates gold and silver leaf, and produces brilliant scintillations from a small steel file. It produces also rotatory motions in delicately suspended wire frames round the poles of a vertical horse-shoe magnet,[1] and all the other effects of voltaic electricity.

Fig. 80.



MrClarke's large machine.

Several very curious and unexpected results were obtained on a magneto-electric machine of very large dimensions, which Mr Clarke exhibited at the meeting of the Electrical Society. The battery was separated into two parts connected by the armatures, the quantity armature being at one side, and the intensity one at the other. The quantity armature had a short coil of thick insulated copper wire, and the intensity one had 15,375 yards of fine copper wire. The intensity arrangement, to the surprise of every body, gave no decomposition, but gave an excruciating, and even dangerous shock, while the quantity arrangement gave one cubic inch of the mixed gases in four minutes. Considering these unexpected results as owing to a compound action produced by the rotation of the two armatures, he arranged the magnets as in his first machines, the only difference being in the size of the new machine, and in the armatures being moved by a crank and treadles. The battery was composed of ten cut and polished steel bars, each four feet long, the whole weighing 156 lbs. According to Mr Noad,[2] the novel results of the experiments were the great amount of gas given by the quantity armature, viz. one cubic inch in one and a half minutes, and the trifling decomposing effect of the intensity armature. The intensity spark was long, straggling, and noiseless, like a spark at the striking distance from the prime conductor of an electrical machine, while the quantity spark had the usual stellar form, but was attended with a loud snapping noise, as in the discharge of a Leyden jar. Both the sparks, however, were equally luminous. By employing a secondary coil, Mr Noad has given shocks with the quantity armature, almost as powerful as those obtained from the intensity one, by using the form of coil first proposed by Professor Callan of Maynooth, and the contact-breaker of Dr Golding Bird.

Dr Bird's method of breaking contact.

The following arrangement (fig. 81) for producing powerful shocks, and strong chemical action by secondary currents, was first given by Dr Golding Bird. Upon a reel, with a hollow axis three inches long, wound about 60 feet of cop-

---

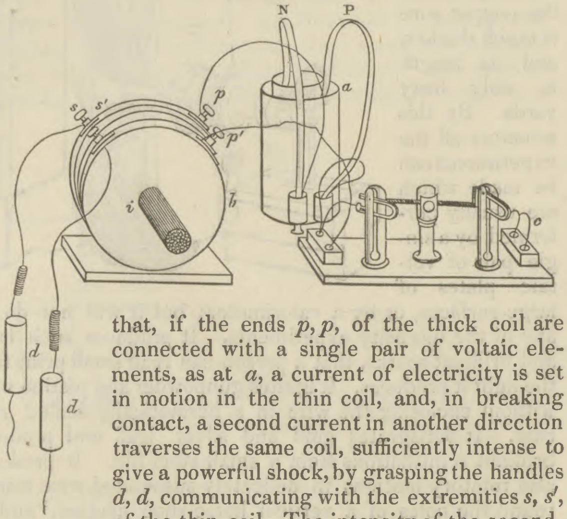
[2] Lectures on Electricity, p. 352.

Dr Bird's method of breaking contact.

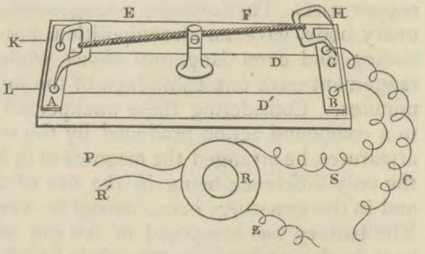
per wire, $\frac{1}{12}$th inch in diameter, covered with cotton thread. The two ends of the wire are connected with *p*, *p′*, by means of binding screws. Over this primary coil is wound a second insulated copper wire, $\frac{1}{80}$th inch in diameter, and about 1500 feet long, and the two ends of this wire are connected with *s*, *s′*, by means of binding screws. From the law of electro-dynamic induction, it is evident that, if the ends *p*, *p*, of the thick coil are connected with a single pair of voltaic elements, as at *a*, a current of electricity is set in motion in the thin coil, and, in breaking contact, a second current in another direction traverses the same coil, sufficiently intense to give a powerful shock, by grasping the handles *d*, *d*, communicating with the extremities *s*, *s′*, of the thin coil. The intensity of the secondary or reduced current is greatly increased, by inserting a bar *i*, of soft wire, or what is better, a bundle of soft iron wires in the hollow axis of the steel, which becomes magnetic.

Fig. 81.



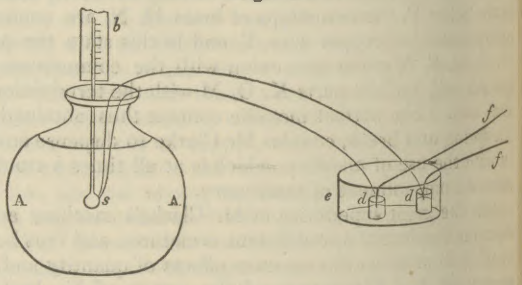
The ingenious method of breaking contact in this arrangement, which we owe to Dr Golding Bird, though shewn in fig. 81, is more distinctly represented in fig. 82. It consists of a base of wood, eight inches long and three broad, having at both ends a piece of hard wood, A, B, each piece having two holes excavated in it to hold mercury. The holes in A communicate with those in B, by thick copper wires D, D. A piece of soft iron wire EF, five inches long, and one-eighth inch diameter, supported with screws with milled heads, moves in a vertical plane upon the upright stem C. Round the wire EF are wound two helices of thin insulated copper wire in the same direction from right to left, so that the two ends of one helix may terminate in the copper points G, H, and those of the other in the points KNL. The small horse-shoe *permanent* magnets, shewn in fig. 82, are fixed on proper supports, near the ends of the bar EF, so that in depressing the end F of the bar, it may be opposite one, suppose the *south* pole of one magnet, and consequently the end E will be opposite the other, the *north* pole of the second magnet. On raising the end F, the contrary will take place, and to effect this the similar poles of the magnet should be in the same direction. Upon connecting the mercury cups in A or B, as shewn in fig. 81, with the small voltaic battery at *a*, the wire EF will become a temporary magnet, if the ends of either helix are allowed to dip in the mercury; and if connection with the battery is properly made, the ends or poles of the temporary magnet will be repelled by the poles of the permanent magnet to which they are opposed; the bar EF will therefore move, and make the ends of the second helix dip in the other cups of mercury,—repulsion will again take place, and so on;—in this way, about 300 oscillations of EF can be obtained in a minute. Upon connecting the ends *p*, *p*, of the thick helix with a single voltaic pair, by means of this contact-breaker, a series of powerful induced currents will be obtained from the extremities *s*, *s′*, of the larger helix. This connection is best made, as in fig. 82, where R is a section of the reel, S one end of the short helix, connected with a cup of mercury in the piece B, Z the other end of the short helix, connected with one plate of the battery, while the wire C connects the other cup of mercury in B with the other plate of the voltaic pair. When the points G, H, K, L, leave the mercury, very brilliant sparks are produced. A loud snapping noise accompanies them, and a vivid combustion of the mercury, clouds of the oxide of mercury being largely evolved. If the ends P, R, fig. 82, or *s*, *s′*, fig. 81, have platinum points, and are immersed in water, acidulated with sulphuric acid, torrents of minute bubbles of oxygen and hydrogen are evolved; and if, instead of water, the points are pressed upon paper, moistened with iodide of potassium, iodine and oxide of potassium are separated. Solutions of sulphate of potash and soap, chloride of potassium, sodium, antimony, and copper, are also rapidly decomposed. Dr Page was the first person who suggested the application of permanent magnets for the purpose of breaking contact, though Dr Bird afterwards, and without knowing this, made the same application.[1]

Fig. 82.



We shall now conclude this chapter with a brief notice of some very recent investigations of Dr Draper of New York, on the electromotive power of heat. The apparatus which he employed is shewn in fig. 83, where AA is a glass vessel about three inches in diameter, with a neck wide enough to receive a mercurial thermometer *b*, and the extremity of a pair of thermo-electric wires about a foot long, and the $\frac{1}{16}$th of an inch in diameter, soldered at *s* with hard solder. The free extremities of these wires dip into the glass cups *d*, *d*, filled with mercury, and immersed in a trough *e*, containing water and pounded ice. By means of the copper wires *f*, *f*, $\frac{1}{6}$th of an inch in diameter, the apparatus is connected with the mercury cups of the galvanometer, the coil of which is of copper wire, $\frac{1}{8}$th of an inch thick, and making only twelve turns round the astatic needles, whose deviations are determined by the torsion of a glass thread, as invented by Dr Ritchie. When a copper and iron wire are used, they indicate temperatures with a promptitude and accuracy quite surprising. In

Fig. 83.



---

[1] See Lond. and Edin. Phil. Mag., Jan. 1838, vol. xii. p. 18; Noad's Lectures, p 364; and Dr Golding Bird's Elements of Nat. Phil. chap. xvii.

us g this apparatus, the vessel AA is filled two-thirds with w er, the bulb of the thermometer being in the middle of th vessel, and the soldered extremity *s* of the wires in conta with it. The wires *f, f,* are then placed in the cups, and th trough *e* filled with water and pounded ice, and carefully su ounded with flannel. The water in AA is then brought tc he boiling point with a spirit-lamp, and kept at that te perature till the astatic needles and thermometer are st dy. For temperatures above 212°, Dr Draper substitu s for the glass vessel a tubulated retort containing q cksilver. Dr Draper's experiments were all made with th metals in the form of wires, and he obtained the follc ing general results:—

. Equal increments of heat do not set in motion equal q ntities of electricity.

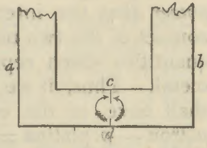
. The tension undergoes a slight increase with increase o emperature.

. The quantity of electricity evolved at any given temp ature is independent of the amount of heated surface, a oint being as efficacious as an indefinitely extended surfa .

. The quantities of electricity evolved in a pile of p rs is directly proportional to the number of the elem ıts.

)r Draper has been led to the following forms of cons ıction, which give peculiar advantages to thermo-elect combinations.

Fig. 84, A.



n fig. 84, A, let *a* be a bar of ant ony, and *b* one of bismuth, sold ed at *c d*, and let the temperature raised at *d*, a current is excited, v ich does not pass round the bars *a*, but in a shorter and readier p h, through the metals between *c* circulating as shewn by the arrows. Nor will the whole c rent pass round the bars till the temperature of the solo ed surface has become uniform. The combination A v l therefore be improved, by giving i he form in fig. B, a part being cut o at the dotted lines. In this form t whole current will be immedi- ly forced to pass along the bars, l in such a pair the temperature v l change very quickly. Dr Dra- considers the form in fig. C, as t best for a thermo-electric couple. this form *a* is a semi-cylindrical bar of imony, *b* one of bismuth, united toher by the opposite corners of a lo- ıge-shaped piece of copper *c*. From extent of surface, the copper becomes ıdily hot and cold, and may be made ry thin. With a pair of bars, three-fourths of an inch thick, l a circular copper plate *c*, with both surfaces blackened, Draper repeated the greater part of those experiments, ich M. Melloni made with his multiplier. Dr Draper ınd that thermo-electric currents, evolved by pairs of different metals, do not differ specifically, like the rays of ht and heat.[1]

Fig. B.

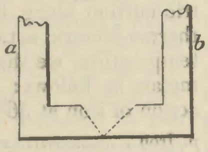


Fig. C.

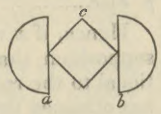


We regret that our limits do not permit us to give an count of some interesting experiments of Mr Noad, on effects of strong and weak electrical currents,[2] on long t coils of considerable breadth of surface, and of varis inventions made in the United States by Dr Henry, Page, and other eminent philosophers, an account of ich will be found in the recent numbers of Professor lliman's *American Journal of Science*.

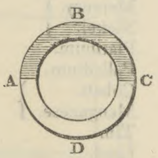
Thermo-Electricity.

CHAP. IV.—ON THERMO-ELECTRICITY.

Seebeck's discoveries.

While investigating the influence of heat in voltaic combinations, Dr Seebeck of Berlin was led to the important discovery that magnetism was developed in two metals forming a circuit, when the equilibrium of temperature in that circuit was disturbed.

Fig. 85.



If A B C D, for example, fig. 85, be a metallic circuit, consisting of an arch of *bismuth*, A B C, and an arch of *copper*, A D C, then if one of the junctions, A, is heated, an electrical current is established, passing into the heated junction from the bismuth to the copper. From many experiments, Dr Seebeck found that, in various circuits formed with bismuth and other metals, the current always passes from the bismuth to the other metals, the bismuth losing *positive* electricity, or becoming *negative* with all the other metals.

The order of the metals, beginning with galæna, in which they are negative in reference to those which precede them, is given in the following table, which, excepting some additions and alterations, was drawn up by Professor Oersted.

Galæna placed above bismuth by Professor Cumming.
BISMUTH.
Mercury placed here by Professor Cumming, but beside lead by Oersted.
Nickel.
Platinum, very variable in its results.
Palladium.
Cobalt.
Uranium.
Manganese.
Titanium.
Tin, English and Bohemian.
Lead,[1] pure lead and that occurring in trade.
Brass, different specimens give different results.
Gold purified by antimony, Oersted, and also that reduced from the oxide.
Copper placed here by Professor Cumming.
Silver purified by cupellation, and also that produced from the chloride.
Uranium.
Molybdenium.
Rhodium.
Iridium.
Zinc, pure and that occurring in trade.
Wolfram.
Cadmium.
Charcoal.
Plumbago.
Steel.
Iron, pure iron and that occurring in trade.
Arsenic.
ANTIMONY.
Tellurium.

Although Dr Seebeck found that most of the metals which stand near each other in the above series produce feeble thermo-electricity, and those more distant a more powerful effect, yet this law did not always hold. *Tellurium*, for example, is less thermo-electric with bismuth, and most of the other metals, than antimony is; and with *silver* it is more effective than most of the metals above it. *Antimony*, too, is more effective with *cadmium* than with mercury; while *iron* is very feebly thermo-electric with most of the other metals, especially *nickel* and *cobalt*.

The effects of the sulphurets Dr Seebeck found to be remarkable. Sulphuret of lead becomes negative even in contact with the bismuth. The sulphurets of iron, arsenic, cobalt and arsenic, and copper, all of which have a *maximum* of sulphur, stand near to bismuth; while all the sulphurets, with a *minimum* of sulphur, have nearly the same power as antimony. The sulphuret of copper, with a minimum of sulphur, occupies a place even below antimony. Concentrated *nitric* and *sulphuric* acids stand above bismuth; while concentrated solutions of *potass* and of *soda* are below antimony and tellurium.

It has been considered probable that the specific heat

[3] Professor Daniel places *lead* before *tin*.

Thermo-Electricity.

and the conducting power of the metals perform a part in the thermo-electric phenomena; but this is not established by observations yet made.

The following table, by Professor Cumming, shews the relations of the thermo-electric and voltaic series, and of the series of conductors of heat and electricity. To these we have added two columns on the optical properties of the metals.

SERIES OF CONDUCTORS.

Thermo-Electric Series.	Voltaic series by acids.	Of Electricity.	Of Heat.	Order of Metals in their degrees of Elliptical Polarization.[1]	Order of Metals in their Refractive Power.
Galæna.	Potassium.	Silver.	Silver.	Pure silver.	Grain tin.[2]
Bismuth.	Borium.	Copper.	Gold.	Common silver.	Mercury.
Mercury.	Zinc.	Lead.	Tin.	Fine gold.	Galæna.
Nickel.	Cadmium.	Gold.	Copper.	Jeweller's gold.	Iron pyrites.
Platinum.	Tin.	Brass.	Platinum.	Grain tin.	Grey cobalt.
Palladium.	Iron.	Zinc.	Iron.	Brass.	Speculum metal.
Cobalt.	Bismuth.	Tin.	Lead.	Tin plate.	Antimony, melted.
Manganese.	Antimony.	Platinum.		Copper.	Steel.
Tin.	Lead.	Palladium.		Mercury.	Bismuth.
Lead.	Copper.	Iron.		Platina.	Pure silver.
Brass.	Silver.			Bismuth.	Zinc.
Rhodium.	Palladium.			Speculum metal.	Iron plate, hammered.
Gold.	Tellurium.			Zinc.	Jeweller's gold.
Copper.	Gold.			Steel.	
Silver.	Charcoal.			Iron pyrites.	
Zinc.	Platinum.			Antimony.	
Cadmium.	Iridium.			Arsenical cobalt.	
Charcoal.	Rhodium.			Cobalt.	
Plumbago.				Lead.	
Iron.				Galæna.	
Arsenic.				Specular iron.	
Antimony.					

The structure or the crystalline arrangement of the particles of bodies seems to exercise some influence over their thermo-electric powers. In a thermo-electric combination of *zinc* and *silver*, for example, the electricity increases with the temperature up to about 250° of Fahrenheit, when it ceases altogether, and by increase of temperature the electric current is re-established in an opposite direction.

Binary combinations.

In order to measure the thermo-electric power of different binary combinations of metals, from the same differences of temperature, a compound circuit must be formed of all those which we desire to compare. The junctions of the metals must be kept at the temperature of melting ice, excepting the junction which is to be made active, and which is to be plunged into hot oil. In this way the mere conducting power of the circuit is the same in every experiment, and the results obtained become strictly comparable.

The following table, given by Becquerel,[3] exhibits the quantities of the currents for a difference of temperature of 36°, of pairs of *eight* metals differently arranged. The lengths of the metals were 7·88 inches, and their diameter about the 200th of an inch. The sign + indicates the metal from which the electric current proceeds.

Thermo-Electric Power of Different Metallic Couples.

	Temperature of junction.	Deviation of needle.	Intensity of currents.
+ Iron and — tin	68°	36·°50	31·°24
+ Copper and — platinum	68	16·00	8·55
+ Iron and — copper	68	34·50	27·96
+ Silver and — copper	68	4·00	2·00
+ Iron and — silver	68	33·00	26·20
+ Iron and — platinum	68	39·00	36·07
+ Copper and — tin	68	7·00	3·50
+ Zinc and — copper	68	2·00	1·00
+ Silver and — gold	68	1·00	0·50

If we compare the numbers in the last column, we shall find, as M. Becquerel states, that, for a temperature of 36°, each metal acquires such a degree of thermo-electric *power* that the intensity of the current, produced by the contact of the two metals, is equal to the difference of the quantities which represent each of these actions in each metal. Thus, if we call the *power* of each metal p, we shall have, in the case of the iron and copper junction, p. iron — p. platina = 36·07. Substracting the first from the second, we have p. copper — p. platina = 8·11, instead of 8·55, given by experiment. The iron and tin junction gives 31·24, and that of copper and tin 3·50. The difference in that of iron and copper is thus 27·74, in place of 27·96 by experiment. The intensity of the thermo-electric current being, therefore, equal to the difference of the thermo-electric action produced in each metal by the same temperature, we shall obtain the powers of each of these metals as follows: Calling the *power*, or thermo-electric action of iron at 36° Fahrenheit, x, we shall have,

p. Iron	x	p. Copper	x — 27·96
p. Silver	x — 26·20	p. Tin	x — 31·24
p. Gold	x — 26·70	p. Platina	x — 36·
p. Zinc	x — 26·96		

Hence, if x were known, we should obtain p upon the supposition that the thermo-electric powers are proportional to the radiating powers of the metals. M. Becquerel has obtained the following numbers:—

Metals.	Thermo-Electric Powers.	Metals.	Thermo-Electric Powers.
Iron	5·	Copper	4·
Silver	4·07	Tin	3·89
Gold	4·052	Platina	3·68
Zinc	4·035		

These values will suit any thermo-electric circuit, and all cases where the thermo-electric power increases with the temperature, that is for all temperatures below 122° Fahrenheit.

M. Nobili[4] formed similar circuits, with substances whose conducting power was inferior to that of the metals. Having made cylinders of porcelain clay, about two and a half inches long, and three and a half lines in diameter, he coiled round the ends of each of them cotton steeped in a conducting liquid, by which they were made to communicate directly with the galvanometer. One end of the cylinder w brought to a point, and after it was made red hot by a pirit lamp, he pressed it against the cold extremity of th other cylinder, when he found that a current was estab ied from the hot extremity to the cold one. This ef fe as M. Becquerel states, arises from the mutual reaction of ie two portions of water of different temperatures.

did not escape the sagacity of Dr Seebeck, that the th mo-electric current might be increased, by forming a co pound thermo-electric current, and arranging the meta couples in a series analogous to those in the voltaic ci uit. Having met, however, with some obstacles in th part of his inquiry, he discontinued the investigation, wl h was taken up without their knowing that he had ente d upon it, by Baron Fourier, and Professor Oersted. T y first employed a hexagonal combination of three pi es of bismuth, and three of antimony, soldered together One side of the hexagon was placed in the magnetic di ction, and a compass put below it. *One* of the juncti was then heated, then *two*, not adjacent, then *three*, alw leaving one junction not heated between the two heated nes. By heating *one* junction the needle deviated some de ees, still more by heating *two*, and still more by heatin *three* junctions. When *three* junctions were cooled wi ice, the other three having the ordinary temperature of e atmosphere, effects still more distinct were produced When *three* alternate junctions were *heated*, and the ot r *three* cooled with ice, the needle deviated sixty degr s.

a rectangular circuit, with twenty-two bars of antim y, and twenty-two of bismuth soldered together, the sa effects were obtained. After dissolving one of the ju tions, a little mercury cup was soldered to each of the di ined bars, so that the circuit could be re-established by ifferent means. A copper wire, four inches long, and 1- th of an inch in diameter, nearly re-established the cu ent; and it was completely re-established by two parallel ieces of the same wire. A wire of the same diamete but *three* feet long, was found a tolerably good condu or; but a platina wire, about sixteen inches long, and 1- th of an inch in diameter, scarcely transmitted a *fortiet* art of the effect. Acids, and solutions of alkalies, and ot r metallic oxides, though good conductors in the volta or hydro-electric circuit, insulated entirely the thermo-ele ric current. The same effect was produced by two di of silver, separated by the thinnest blotting paper, m tened with sulphate of copper. In these experiments, th ntensest current produced no chemical effects, no igni n of the wires, and no electric condensation; but a pr ared frog was made to palpitate.

thermo-electric currents, which differ only in lengths, th shortest is the most powerful, a circuit of double le th having little more than half the effect. In order to fi the law of increased effect, as depending on the numbe of junctions, Professor Oersted composed circuits of eq l length with different numbers of junctions.

fig. 86, is shewn a simple circuit consisting of one ba *a a*, of antimony, and one, *b b*, of bismuth, and in fig. 87 complex circuit of the same length and materials.

Fig. 86.

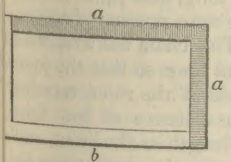

Fig. 87.

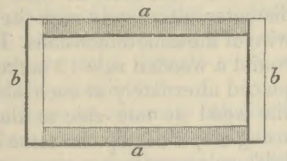

When one of the junctions in fig. 86 was heated or cooled, and two of the junctions at the extremities of the diagonals in fig. 87, heated or cooled to the same degree, the deviation of the needle was 22° in the first case and 30° in the second.

Thermo-Electricity.

In like manner, open circuits, as in figs. 88, 89, having each the same length, but double that of the preceding two, had, the one *one* junction, and the other *three* junctions, heated or cooled equally, the first gave a deviation of about 14°, and the other nearly 32°.

Fig. 88.

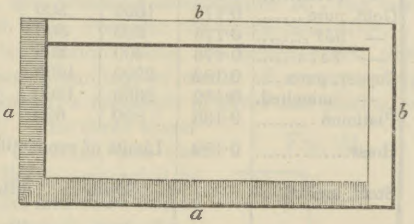

Fig. 89.

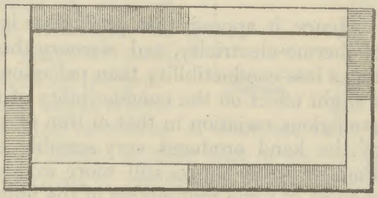

"In several complex circuits," says Professor Oersted,[1] "it is found that the heating or cooling of one junction only produces twice the angular deviations of that added by the addition of one active junction more. The effect of one active junction, when the others are at rest, is, by experiment, found to be twice the effect of all the arrangements divided by the sum of the elements + one. The effect of each addition of a new active junction is only *half* this quantity, and seems even to be in a decreasing ratio when the number of junctions is great."

M. Pouillet's researches.

From these and other observations, it appears that the thermo-electric current produces a prodigious quantity of electricity, but in a state of very feeble intensity, while the voltaic current has a very great intensity. The former is impaired by the resistance opposed to it by a long multiplying wire, while the latter is increased in surmounting this resistance. M. Pouillet has endeavoured to compare the intensity of these two currents, by passing the hydro-electric current through a platinum wire long enough to reduce it to an intensity which will just balance the thermo-electric current. In one case he found that 590 feet of platinum wire, ·006 of an inch in diameter, including the resistance of the battery, reduced a hydro-electric current, produced by twelve pair of plates with double coppers, to an equilibrium with that of one thermo-electric pair of bismuth and copper, in a circuit of 65·6 feet of copper wire, ·039 of an inch in diameter, with a difference of temperature of 76° Fahrenheit. By computing the rotation between the electro-motive forces and the resistance in these two cases, he found that the hydro-electric current had an intensity 114,000 times greater than that of a single pair of bismuth and copper, produced by a difference of temperature, between the two junctions, of 108° of Fahrenheit.[2]

Conductibility of metals for thermo-electricity.

In order to compare the conductibility of metals for thermo-electro currents, M. Pouillet[3] employed *two* equal thermo-electric currents. The *first* was weakened by making it traverse the metallic wire submitted to experiment, and the *second* was weakened precisely the same quantity, by traversing lengths, more or less great, of another wire, which served as the term of comparison. The following table shews the results of this comparison, the conductibility of pure mercury being reckoned 100.

Thermo-Electricity.

Conductibility of metals for thermo-electricity.

Names of Substances.	Diameter of wire.	Length of wire submitted to experiment.			Conductibility, that of mercury being 100.
	Millim.	Millim.	Millim.	Millim.	
Palladium	0·176	1900	1200	500	5791
Silver 963, pure.	0·174	2000	1500	200	5152
— 900	0·194	2000	1500	200	4753
— 857	0 178	1200	800	400	4221
— 747	0·179	1200	600		3882
Gold, pure	0·176	1000	500		3975
— 951	0·176	600	300		1338
— 751	0·176	400	206		714
Copper, pure	0·182	2000	1000	500	3838
— unmelted.	0·182	2000	1000	500	3842
Platinum	0·186	800	600	300	855
Brass	0·182	Limits of conductibility.			1260 900
Steel, melted		Ditto ditto.			800 500
Iron		Ditto ditto.			700 650

Hence it appears that *palladium* is the best conductor of thermo-electricity, and *mercury* the worst, having *sixty* times less conductibility than palladium. That which has a slight effect on the conductibility of mercury produces a prodigious variation in that of iron or steel. Even the heat of the hand produces very sensible effects, and what M. Pouillet justly thinks still more wonderful, the heating to redness of some millimetres of the length of a wire of iron or steel, is sufficient to make its conductibility *three* or *four* times less.

Intensity of thermo-electric currents.

When thermo-electric currents are produced by a single element, and the thermo-electric power remains the same, M. Pouillet found that the intensity of the current which it produces, is inversely as the length of the circuit, and directly as the conductibility of the wire or rod which forms the current. He found, also, that in a thermo-electric circuit, composed of wires of different sections, the elementary force of the current is the same in all powers, if we take equal intervals on these different wires the direct currents will be found to have different intensities, which are nearly in the inverse ratio of the sections of the wires in the intervals of deviation. M. Pouillet succeeded, also, in establishing the curious fact, which had been recognised by M. Marianini,[1] that several electric currents propagate themselves in the interior of bodies, as if they were alone, like light and heat.

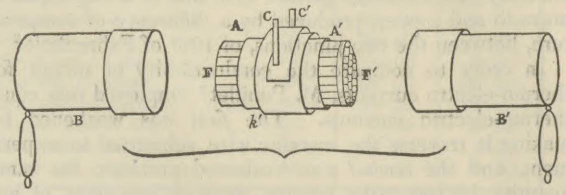
Thermo-electric piles.

The first persons who succeeded in constructing thermo-electric piles, were MM. Nobili and Melloni, who employed them successfully in their experiments on radiant heat. This instrument, however, has since been improved by Melloni, and we shall, therefore, describe it in preference after M. Becquerel.

Melloni's.

M. Melloni constructed his thermo-electric pile of fifty small bars of bismuth and antimony placed in a bundle, as shewn in fig. 90, the length of the bundle being 30 millimetres, and its section 96 centimetres square. The two terminal faces are blackened. The bars of bismuth, which alternate with those of antimony, are soldered at their extremities, and separated throughout their whole lengths by an insulating substance. The first and the last bar have each attached to them a copper wire, abutting against one of the pins *c*, *c*′, of the same metal, passing through a piece of ivory fixed in the ring AA′. The interval between the interior surface of this ring and the elements of the pile is filled with insulating matter. The free extremities of the two wires communicate with the ends of the wire of a multiplier, the needle of which indicates when the temperature of the anterior face of the pile rises or falls above that of the posterior face. Two metallic tubes B, B, polished without, and blackened within, are fitted to the two ends of the pile, to protect them from lateral radiations.

Fig. 90.



The multiplier is shewn in fig. 91, where AB*c* is the frame enveloped by the copper wire, whose extremities abut against the metallic tubes FF′, fig. 92. This frame is fixed on a horizontal stage DE, which can turn in its own plane, and round its centre, by means of a toothed wheel and pinion placed below, and moved by the milled head G. MN is the support of the astatic system of the two magnetic needles, suspended by the silk fibre VL, and the cylinder of glass RS covers the apparatus, and rests on the base KI. Fig. 92 is a section of the apparatus, by a plane passing through the support, and one of the tubes of communication. The needles are 53 millimetres long, the diameter of the copper wire is 0.76 mm., and it is doubly covered with silk, and makes 150 circumvolutions round the frame, which is 6 millimetres high, having its length a little greater than that of the needles.[2]

Fig. 91.

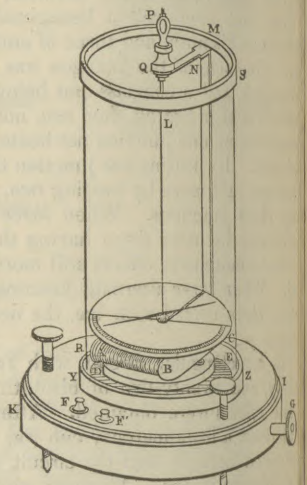


Fig. 92.

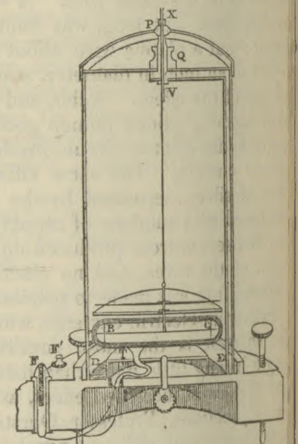

We have already seen that thermo-electricity possesses the same general characters as common and voltaic electricity. Althoug Oersted failed in obtaining chemical action from his therm electric combinations, yet Professor Botto[3] of Turin subse quently decomposed acidulated water. His apparatus co sisted of a metallic wire or chain, composed of 120 pieces platinum wire, each an inch long, and $\frac{1}{100}$th of an inch i diameter, alternately with the same number of pieces of so wire of the same dimensions. This chain was wrapped spiral round a wooden rule 18 inches long, so that the joints we placed alternately at each side of the ruler, receding fro the wood at one side to the distance of four lines. E using a spirit-lamp the same length as the helix, and a N bili's galvanometer, a very energetic current was shewn exi and the decomposition of acidulated water was incre ed, by substituting copper in place of platinum poles, in v ich case hydrogen only was set free. An increased tem erature augmented the current and the decomposition. M. otto obtained still more powerful effects by a pile of bis th and antimony, consisting of 140 elements forming a p llelopiped, with a base of 2¼ inches, and a height of 1 in.

[2] Becquerel's Traité, &c. tom. iii. p. 425.

[3] Bibliothèque Universelle, Sept. 1832.

A distinct electric spark has also been obtained from the ther o-electric pile, by the Chevalier Antinori of Florence. Pro ssor Linari[1] of Sienna verified this result with a Nobili' pile of 25 elements and temporary magnet, with an elec o-dynamic spiral 805 feet long. With this apparatus obtained a brilliant spark visible in open day, whenever he contact was broken. With this pile and temperatu s from freezing to boiling water, he readily decompose water, and also nitrate of silver. The same thermo-elec ic current magnetised an unmagnetic needle, and prod ced the phenomenon of the palpitation of mercury. Pro sor Wheatstone verified these experiments in 1837, by hermo-electric pile of 33 elements of bismuth and anti ony, forming a bundle three-fourths of an inch in diameter, d 1⅕th long. The poles were connected by two thick wire with a spiral of copper ribbon 50 feet long and 1½ inch road, the coils being insulated by brown paper and silk. One face of the pile was heated by red-hot iron brou ht near it, and the other cooled by ice. Two strong wire connected the poles of the pile and the spiral, and the ntact was broken, when necessary, in a mercury cup, betw en one extremity of the spiral and one of these wires. A d inct spark was seen in open day whenever the contact as broken.[2]

T e thermo-electric pile has been greatly improved by Mr atkins, who employs a flat copper ribbon coil. In pile arying from 15 to 30 pairs of elements, he obtains bril nt sparks, by merely pouring hot water on one end, whi the other has the temperature of the air.

P fessor Andrews of Belfast has recently succeeded in dev ping thermo-electric currents, by simply bringing two etallic wires at different temperatures into contact with fused salt, between which and the wires no chemical tion takes place. This result he first obtained by mea of fused borax. He took two similar wires of platina nd connected them with the extremities of the copper ire of one of Gourjon's galvanometers, and fused a sma globule of borax in the flame of a spirit-lamp on the free xtremity of one of the platina wires, and having introd ed the free extremity of the other into the flame, he brou ht the latter, raised to a higher temperature than the form r, into contact with the fused globule. When this was one, the needle of the galvanometer was instantly driv with great violence to the limit of the scale. The dire ion of the current was always from the hotter platina wire through the salt, to the colder wire. Professor Andre obtained a permanent electric current in the same dire ion, by simply fusing the globule between the two wir and applying the flame of the lamp in such a manner, hat the wires, at their points of contact with the fused salt ad different temperatures. Fused carbonate of soda gav similar, but more powerful currents than borax. Carbon e of potash, chloride and iodide of potassium, sulphate of la, chloride of strontium, heated glass, &c. produced sim r currents; and even boracic acid, though such an imp fect conductor, deflected the needle 40°.

e currents thus produced have an intensity inferior to tha f the hydro-electric currents, and they are capable of dec nposing with great facility water and other electrolytes. B fore the salts were actually fused, Professor Andrews found that electrical currents were generated whose directions no longer followed the simple law, but varied in the most singular and perplexing manner, passing first from the hot to the cold wire, then by more heat from the cold to the hot, and by more heat still from the hot to the cold wire.

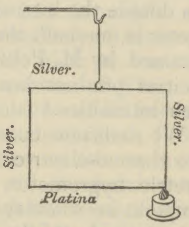
Thermo-Electricity.

Professor Andrews obtained similar currents, by interposing certain minerals between unequally-heated platina wires. *Mica*, heated very strongly, caused a deflection in the needle of 7°, and *Stilbite* a deflection of 25°, the current being in both cases from the hot to the cold wire[3].

Thermo-electric rotations.

Thermo-electric rotations were, we believe, first produced by Professor Cumming, by means of a very simple apparatus. He formed a rectangle of silver and platina, as shewn in fig. 93. The three upper sides are formed of silver, and the lower of platina. When suspended, as shewn in the figure, and when one of the junctions was heated, it revolved from *left* to *right*, when the pole of a magnet was presented to another junction. When the rectangle was suspended upon the loadstone itself, and heat applied to one of the junctions, the rectangle soon began to turn.

Fig. 93.



When a chain or wire, consisting of alternate links, or pieces of *platinum* and *silver*, is made part of the voltaic circuit, the links or portions of *platinum* wire will become *red-hot*, while those of *silver* remain *dark*, and comparatively *cold*.

Peltier's researches.

In studying the effects of thermo-electric currents, M. Peltier made the interesting discovery, that *cold*, instead of heat, is produced at the points of junction of certain crystallisable metals. The instrument by which he obtained these interesting results is shewn in fig. 94, where A B are two thermo-electric couples in bismuth and antimony, C a copper wire which unites the antimony a' of the upper couple to the bismuth b of the lower couple. D, E, copper wires communicating with the galvanometer G of 84 coils, and completing the circuit between the upper bismuth B$''$, and the lower antimony a'. F, H are the free extremities of a'', b'', which form a pair of pincers, which press against each other by a spring. The bar JK is formed by a bar of antimony a''', and of bismuth b''', which ought to traverse the electric current. L, M, M$'$ are conductors of the pile P, N a plate of copper, with a graduated circle and magnetic needle O, for measuring the quantity of electricity which passes through the entire circuit M M$'$, N, K, b''', a''', L, P. The galvanometer G indicates the electricity produced by the variations of temperature of the ends F, H, resulting from those of the bars J, K, the closed circuit of this electricity being a', C, a''', E$'$, c, D, b'', a'. The ball A of an air thermometer (with its capillary tube E plunged in a vessel d of coloured alcohol) is crossed by a compound

Thermo-Electricity.

Peltier's researches.

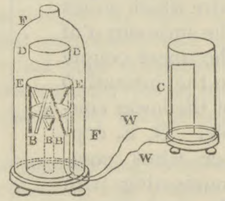
bar of a^{iv}, b^{iv}, of bismuth and antimony united at S′. A graduated scale is placed behind the thermometer tube E′. The current of the pile P is received by copper conductors F, G.

If we now place wires of different metals between the thermo-electric pincers F, H, and vary the intensity of the current, we shall observe a rise of temperature when the conductors are homogeneous, the heat being the same throughout the whole length of the wires, with the exception of their extremities, where it increases or diminishes according as the pincers which retain the wire are worse or better conductors than itself. When copper pincers are used, a depression of temperature is felt at the distance of two or three centimetres, according to the intensity of the current. M. Peltier has found that when the current has double the intensity, or when the section of the conductor is one-half, the temperature is tripled. The results obtained by M. Peltier tend to prove that the two electricities produce heat by their union, however feeble be their intensities.[1]

Peltier's thermo-electric hygrometer.

We shall now conclude this article with a description of two thermo-electric instruments, viz. M. Peltier's thermo-electric hygrometer, for determining by the change of temperature whether a solution or a chemical combination has taken place when two bodies are brought into contact, and Mr Locke's thermoscopic galvanometer. M. Becquerel had long ago shewn that when a simple solution takes place, no electrical effect is produced, but that when two substances chemically combine, positive electricity passes from an alkali to an acid, and negative electricity from an acid to an alkali. The nature of the electric wires therefore determine by means of a multiplier, whether combination or simple solution has taken place. But as a change of temperature also takes place, M. Peltier has employed this as the means of deciding whether solution or combination has taken place, cold being produced in the one case, and heat in the other. This hygrometer is shewn without the galvanometer in fig. 95, where A is a wooden disc for supporting the thermo-electric couples, being itself supported by a rod and a bar; B, B, B, three couples of bismuth or antimony forming the thermoscopic support; W, W, the wires leading to the multiplier; D, a platina capsule filled with distilled water, which is to be placed on the couples; E E, a cylinder of card; and F F, a glass receiver open at top, but surrounded with paper to prevent radiation. When distilled water is placed in the capsule, its spontaneous evaporation produces a depression of temperature which varies ordinarily from 40° to 60°[2]. As this apparatus is very sensible, the needle of the multiplier arrives rapidly at 90°; but this inconvenience is removed by placing in the circuit supplementary conductors, which diminish the intensity of the current, and bring back the needle to the first 20°. Tables are then formed which give the ratio between the deviations of t needles, the intensities of the current, and the difference a very extended scale is thus formed which may begin 150° above zero, and descend indefinitely. To compa this instrument, we have only to determine the extren dryness produced with muriate of lime placed in a clo vessel. When the saturation of the air produces no evapor tion, the capsule remains at the surrounding temperatu and the needle at zero. When we have determined t force corresponding to the number of degrees given by e treme dryness, we divided this force into 100 parts, corre ponding to 100 degrees of ordinary hygrometers.

Fig. 95.



Dr Locke, professor of chemistry in the medical colle of Ohio, has lately constructed a new thermoscopic ga vanometer, the peculiarity of which is the massiveness the coil, which affords a free passage to currents of t most feeble intensity, and enables them to deflect a ve heavy needle. The coil is made of a copper fillet about feet long, one-fourth of an inch wide, $9\frac{1}{8}$ thick, and weighi between 4 and 5 pounds. This coil is not made in a p at the diameter of the circle in which the needle is to r volve, but is opened out, the several turns lying side side, and covering almost the whole of that circle abo and below. It is wound closely and in parallel turns on circular piece of board $11\frac{1}{2}$ inches in diameter, and half inch thick, covering the whole of it except two small posite segments of about 90° each. The board being e tracted, leaves a cavity of its own shape, to be occupied the needle. The copper fillet is not covered with silk any other coating, but the turns of it are separated at th ends by veneers of wood just so far as to prevent conta throughout. The coil is supported on a wooden ring wi brass feet and levelling screws, and surrounded by a bra hoop with a flat glass cover, in the centre of which is i serted a brass tube for suspending by a silk fibre, one of N bili's double astatic needles, each part being about 11 inch long, one-fourth of an inch wide, and $\frac{1}{60}$th thick. The low part plays within the coil, and the upper part above it, and t thin white deal placed upon it. This instrument is pec liarly fitted for experiments in a class. It is very sensil to a single pair of thermo-electric metals, to the action which it seems peculiarly adapted. With a battery of fi couples of bismuth and antimony, the radiation of a pers 12 feet distant, without any reflector, and when the te perature of the air was 72°, moved the needle sensibly. a thermo-electric pile, massive in proportion to the coil, used, this thermoscope would exhibit the experiments Melloni satisfactorily to a large class. A more detail account of this instrument will be found in the Lond and Edinburgh Philosophical Magazine, October 18 vol. xi., p. 378.

For further information on thermo-electricity, and t other subjects of which this article treats, the reader is ferred to M. Becquerel's admirable work, entitled *Tra Experimentale de L'Electricité et du Magnetisme, et leurs rapports avec les phenomenes naturels.* Five volum i. and ii., Paris 1834; iii., 1835; iv., 1836; and v., 18

VOLTAIRE, François Marie Arouet de, one of the most celebrated writers of modern times, was born at Paris on the 20th of February 1694. His father, François Arouet, was "ancien notaire au Chatelet," and treasurer of the chamber of accounts; his mother was Marguerite d'Aumart. At the birth of this extraordinary man, who lived to a great age, there was little probability of his being reared, and for a considerable time he continued remarkably feeble. In his earliest years he displayed a ready wit and a sprigh imagination; and, as he said of himself, made verses bef he was out of his cradle. He was educated under Fath Poré, in the College of Louis the Great; and such w his proficiency, that many of his essays are now existin which, though written when he was between twelve a fourteen, show no marks of juvenility. The famous Nin de l'Enclos, to whom this ingenious boy was introduc left him a legacy of 2000 livres to purchase a library. Having been sent to the schools of law, he was so disgusted with the dryness of the study, that he devoted himself entirely to the muses. He was admitted into the company of the Abbé Chaulieu, the marquis de la Fare, the duke de Sully, the grand prior of Vendôme, Marshal Villars, and the chevalier du Bouillon; and caught from them that easy taste and delicate humour which distinguished the court of Louis XIV. Voltaire had early imbibed a turn for satire; and, for some philippics against the government, was imprisoned by the regent, the duke of Orleans, almost a year in the Bastille. He had before this period produced the tragedy of *Oedipe*, which was represented in 1718 with great success; and the duke of Orleans happening to see it performed, was so delighted that he obtained his release from prison. The poet waiting on the duke to return thanks, "Be wise (said the duke), and I will take care of you." "I am infinitely obliged (replied the young man); but I entreat your royal highness not to trouble yourself any further about my lodging or board."

[2] The degrees of the galvanometer we presume. M. Becquerel's Traité, &c., tom. v., p. 243.

In 1722 he made an excursion to Brussels, where he became acquainted with Jean Baptiste Rousseau; but Rousseau was jealous of a rival, and the poets soon became disgusted with each other. On his return to Paris in the same year, he produced his tragedy of *Mariamne*, which was not very favourably received. He began his *Henriade* before he was eighteen. Having one day read several cantos of this poem when on a visit to his intimate friend, the young president de Maisons, he was so teased with objections, that he lost patience, and threw his manuscript in to the fire. The president Henault with difficulty rescued it. "Remember (said Mr Henault to him in one of his letters) it was I that saved the Henriade, and that it cost me a handsome pair of ruffles." Some years after, several copies of this poem having got abroad, while it was only a sketch, an edition of it was published, with many chasms, under the title of "La Ligue." It gave great offence to the bigots; and the poet was considered as highly criminal for praising Admiral Coligny and Queen Elizabeth.

His reckless vivacity and frequent attacks on religion, subjected him to many mortifications; and he was a second time imprisoned in the Bastille, in consequence of a broil with the Chevalier de Rohan. After an imprisonment of six months he was released on condition of quitting the kingdom, on which he chose England for his retreat, and took with him the *Henriade*, in order to finish the work, and republish it in a land of liberty. He was favourably received by George I., and still more so by the princess of Wales, afterwards Queen Caroline, who procured for him a great many subscriptions, which laid the foundation of his fortune; for, on being permitted to return to France in 1728, he put the money he had acquired, into a lottery established by M. Desfortes, comptroller-general of the finances, by which, and other fortunate speculations, he realized considerable property.

His *Lettres Philosophiques*, abounding in bold expressions and indecent witticisms against religion, having been burnt by a decree of the Parliament of Paris, and a warrant being issued for apprehending the author in 1733, Voltaire prudently withdrew, and was sheltered by the marchioness du Chatelet, in her castle of Cirey, on the borders of Champagne and Lorraine, who entered with him on the study of the system of Leibnitz, and the Principia of Newton. A gallery was built, in which Voltaire formed a good collection of natural history, and made an infinite number of experiments on light and electricity. He laboured in the mean time on his Elements of the Newtonian Philosophy, then totally unknown in France, and which the numerous admirers of Des Cartes were little desirous should be known. In the midst of these philosophic pursuits he produced the tragedy of *Alzire*. He was now in the meridian of his age and genius, as was evident from the tragedy of *Mahomet*, first acted in 1741; but it was represented to the procureur-general as a performance offensive to religion; and the author, by order of Cardinal Fleury, withdrew it from the stage. *Merope*, played two years after, 1743, is a species of tragedy, unprecedented on the French stage, being without any intermixture of love, yet abounding in pathos. It was at the representation of this tragedy, that the pit and boxes were clamorous for a sight of the author; yet it was severely criticised when it came from the press. He now became a favourite at court, through the interest of Madame d'Etoiles, afterwards marchioness of Pompadour. He was appointed a gentleman of the bed-chamber in ordinary, and historiographer of France. He had frequently attempted to gain admittance into the Academy of Sciences, but could not obtain his wish till 1746, when he was the first who broke through the absurd custom of filling an inaugural speech with the fulsome adulation of Richelieu; an example soon followed by other academicians. From the satires occasioned by this innovation he felt so much uneasiness, that he was glad to retire with the marchioness du Chatelet to Luneville, in the neighbourhood of King Stanislas. The marchioness dying in 1749, Voltaire returned to Paris, where his stay was but short. The king of Prussia now gave Voltaire an invitation to live with him, which he accepted towards the end of August 1750 On his arrival at Berlin, he was immediately presented with the Order of Merit, the key of chamberlain, and a pension of 20,000 livres. Here great respect was paid to him. His apartments were under those of the king, whom he was allowed to visit at stated hours, to read with him the best works of either ancient or modern authors, and to assist his majesty in the literary productions by which he relieved the cares of government. But a dispute which arose between him and Maupertuis soon occasioned his disgrace. Maupertuis was at some pains to have it reported at court, that one day while General Manstein happened to be in the apartments of M. de Voltaire, who was then translating into French the Memoirs of Russia, composed by that officer, the king in his usual manner sent a copy of verses to be examined, when Voltaire said to Manstein, "Let us leave off for the present, my friend; you see the king has sent me his dirty linen to wash, I will wash yours another time." It was about this time that Maupertuis published his very strange Philosophical Letters; and M. de Voltaire did not fail to heighten, with his utmost powers of raillery, every thing which he found, or could make ridiculous, in the projects of Maupertuis, who was careful to unite his own cause with that of the king, and succeeded in provoking his displeasure against Voltaire, who was considered as having failed in respect to his majesty; and therefore, in the most respectful manner, he returned to the king his chamberlain's key, and the cross of his Order of Merit, accompanied with four lines of verse, in which he, with great delicacy, compares his situation to that of a jealous lover, who sends back the picture of his mistress. The king returned the key and the ribbon; but this act was not followed by an immediate reconciliation. Voltaire now paid a visit to her highness the duchess of Gotha, who honoured him with her friendship as long as she lived. While he remained at Gotha, Maupertuis employed all his batteries against him: Voltaire was arrested by the king's orders, but was afterwards released.

He now wished to obtain permission to reside at Paris, which might have been granted, had not his witty and licentious poem, "La Pucelle d'Orleans," caused a great clamour against him. He therefore purchased a country house near Geneva; but his restless disposition having afterwards in-

Voltaire.

volved him in the party squabbles of the place, he found it necessary to quit the republic; and he purchased the castle of Ferney in France, about a league from the lake of Geneva. It was here that he undertook the defence of the well-known family of Calas; and not long after he had a second opportunity of vindicating the innocence of another condemned family of the name of Sirven. It is somewhat remarkable, that in the year 1774, he had the third time a singular opportunity of employing that same zeal which he had displayed in the fatal catastrophe of the families of Calas and Sirven.

From this retreat he poured out an exhaustless variety of works, which were extensively circulated and eagerly read. They generally breathed a spirit of hostility to civil and ecclesiastical tyranny; but his attacks on priestly domination too often degenerated into insidious and flagitious attacks on revealed religion, and pure morality. Here Voltaire long continued to enjoy the pleasures of a rural life, and the admiration of the wits and philosophers of Europe. He could number among his correspondents and pupils some of the greatest sovereigns of the age. The king of Prussia renewed his correspondence with him, and Catherine II. of Russia sent him valuable presents. Paris was filled with his admirers, and his principles were daily making progress in that capital. Wearied at length with his isolated situation, or yielding to the importunities of friends, he came to Paris about the beginning of the year 1778. On his arrival, the French Academy deputed three of their members to congratulate him, and placed his bust beside that of Corneille. His bust was also crowned in the theatre on the sixth representation of his new tragedy of *Irene*. He did not long survive this farce: for having overheated himself with receiving visits, and exhausted his spirits by supplying a perpetual fund of conversation, he was first seized with a spitting of blood; and at last becoming restless in the night-time, he was obliged to use a soporific medicine. Of this he one night took so large a dose, that he slept thirty-six hours, and expired a very short time after awakening from it. He died on the 30th of May 1778, in the eighty-fifth year of his age.

When near his end, the marquis of Vilette, with whom he resided, sent for the rector of St Sulpice to visit him. Of this interview various very contradictory accounts have been published; but it is certain that he did not receive the last ceremonies of the catholic church. In consequence, it is said, of the refusal of the archbishop of Paris to allow him Christian burial, he was interred secretly at Sellices, a Benedictine abbey between Nogent and Troyes, whence his remains were in 1791 removed by order of the national assembly, and interred in St Genevieve.

The following is a sketch of his character as drawn by Marmontel: "He had sought glory by all the roads that are open to genius, and had deserved it by immense labours and brilliant successes. The arm of ridicule was the instrument of his vengeance, and he wielded it most fearfully and cruelly. But the greatest of blessings, repose, was unknown to him. It is true that envy at last appeared tired of the pursuit, and began to spare him on the brink of the grave. On his return to Paris, after a long exile, he enjoyed his renown, and the enthusiasm of a whole people, grateful for the pleasures that he had afforded them. The weak and last effort that he made to amuse them, *Irene*, was applauded as *Zaire* had been; and this representation, at which he was crowned, was for him the most delightful triumph. But at what moment did this tardy consolation reach him, the recompense of much watching? The next day I saw him in his bed. 'Well,' said I, 'are you at last satiated with glory?' 'Ah! my good friend,' he replied, 'you talk to me of glory, and I am dying in frightful torture.'"

The works of this extraordinary man are very numerous and various. Voltaire is beyond dispute the most popular writer in the French language; and his genius and wit are at least equalled by his levity and profaneness. As an author, he was most anxious for his reputation as a dramatist and a poet. His *Henriade* is probably the best epic in the French language, though little distinguished by fancy or invention. As a dramatist he ranks after Corneille and Racine. In comedy he was not very successful. In history he is rather agreeable and ingenious than accurate and profound. His style in prose is lively, pointed, and unaffected, admirably adapted for the numerous smaller works that came from his pen in the form of tales, romances, dialogues, and pasquinades. His raillery was of the most poignant character, and his power of exciting ridicule unbounded. Scarcely any writer ever launched into the world publications so voluminous and various, which followed one another with unexampled rapidity. The first collective edition of his works was published at Geneva in 1768, in 30 volumes 4to. A more complete collection appeared at Basel, 1784–9, 71 tom. 8vo. Of his more popular works, editions are continually multiplying at all prices and in all sizes.

VOLTERRA, a city of Italy in the Grand Duchy of Tuscany, the capital of a circle called a vicarate, of the same name, and the seat of a bishop. It stands on a hill, and is surrounded with walls of Etruscan construction. It has a cathedral and several churches, and contains 6200 inhabitants. Volterra is celebrated for its salt springs, from which culinary salt is manufactured. Near the city are quarries of marble and of alabaster, and some mines of fossil coal.

VOLUME, a book or writing of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, "to roll up;" the ancient manner of making up a book being in rolls of bark or parchment. See BIBLIOGRAPHY.

VOLUNTARY, in *Music*, means properly an extempore composition played upon the organ, or some other instrument. In Great Britain, from want of thorough musical education, there are very few performers who can safely attempt any thing of this kind. In Germany there are many.

VOLUTE, in *Architecture*, a kind of spiral scroll used in Ionic and Composite capitals, whereof it makes the principal characteristic and ornament.

VOMITING, a retrograde spasmodic motion of the muscular fibres of the œsophagus, stomach, and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm; which when gentle create a nausea, when violent a vomiting.

VORALBERG, a circle of the Austrian province of Tyrol, which touches on the lake of Constance. This locality renders it of some importance to the imperial dominions. It extends over 1628 square miles, and comprehends three cities, seven market towns, and 412 villages, with 79,600 inhabitants. It is a mountainous and highly picturesque district, yielding little besides Alpine pasture for cattle. The capital is the city of Bregentz, built on a hill overlooking the lake of Constance.

VORSTIUS, CONRAD, born at Cologne on the 19th of July 1569, was the son of a dyer who had secretly adopted the Protestant faith. Having received a good preliminary education, he in 1587 entered the College of St Lawrence at Cologne. After lecturing at Geneva, he was appointed professor of theology at Steinfurt, where he continued till 1610, when he succeeded Arminius in the professorship of theology at Leyden. Here he composed his "Tractatus Theologicus de Deo, sive de Natura et Attributis Dei." This brought on him the accusation of heresy, and engaged both individuals and universities in the controversy. James the First drew up a large catalogue of the heresies which it contained, and caused the work to be b ned in London. He moreover informed the States that if hey did not dismiss Vorstius, none of his subjects would b permitted to visit Leyden ; and such was the odium ra ed against him from other quarters, that he was ultim ely dismissed from his office, and banished, by the States of Holland, from their territory. After spending two years in oncealment, frequently changing his abode for fear of hi life, he received an asylum from the duke of Holstein, w had assigned to the dispersed followers of Arminius a pi e of ground for building a town. He died shortly after at Toningen, on the 29th of September 1622, at the age of fi -three.

VOSGES, a department in the north-east of France, fo ned out of the southern part of the ancient province of L raine, and extending in north latitude from 48° 31′ to 4 7′, and in east longitude, from 5° 30′ to 6° 12′. It is b nded on the north by the departments of the Meuse a the Meurthe, on the east by those of the Upper and o the Lower Rhine, on the south by that of the Upper S ne, and on the west by the Upper Marne. It contains 2 8 square miles, and returns three members to the Chamb of Representatives. Vosges is divided into five arrond ements, thirty cantons, and 547 communes, and in 1836 h a population of 411,034 souls. They all adhere to the C holic church, are of German origin, and though active a careful, are for the most part excessively poor. The s face of the department is for the most part mountainous a woody. The Vosges mountains, which are a prolongat n of the Jura, stretch in a direction from east to west f n Beford to Langres, and in the north join the Hundsruck. I these are vallies of greater or less extent, and capable o cultivation. The highest point of the mountains is the I ch, whose summit rises to the height of 4320 feet. Cons erably more than one-third of the land is covered with w ods. The soil in the eastern part is a mixture of sand a stones, and is very unproductive. In the western parts i s calcareous, and covered with a heavy clay, and though c icult to work, is the most productive division ; but the w ole does not grow sufficient corn for the consumption. A the mountains are covered with snow during the greater p t of the year, the climate is raw and cold, but is not c emed unhealthy. The mountains are the sources of s eral streams. The chief of them is the Moselle, which t es a northerly direction, and soon enters Meurthe, and f lly falls into the Rhine. The other rivers are the M use, the Meurthe, the Saone, the Breusch, and the Ma n ; and there is a great number of smaller streams.

The productions of the land are cattle, chiefly cows and s ne, fruit, wax, honey, corn, wine, flax, and hemp ; but t most important are from the forests, which supply by m ans of numerous saw-mills a vast quantity of wood, both f building and for fuel. There are quarries of marble, a l mines yielding silver, lead, and copper in small port ns ; but the iron mines are the most important. Some s all articles of manufacture are produced ; but the po ty of the inhabitants is such, that they have little power o consuming luxuries of foreign growth, and have no other t de than that of selling the few low-priced commodities w ich their soil produces.

VOSSIUS, Gerard John, a writer of great and varieg ed erudition, was born near Heidelberg in the year 77. His father, John Voss, and his mother, Cornelie de e, were both natives of Roermund, a town in the Netherl ds. Having embraced the doctrines of the Reformation, emigrated to the Palatinate, where he studied divinity, and i 1575 became a minister in the vicinity of Heidelberg ; t on refusing to adopt the Lutheran creed on the subject o the eucharist, he found it advisable to revisit his own c untry. Here he successively discharged the duties of a p stor in different places. His wife died at Dordrecht in 84. He afterwards married Anne de Witt, but scarcely survived for three months. His son, who was thus left an orphan, received his early education at Dordrecht, and at the age of eighteen, was sent to the university of Leyden, where he studied Greek under Vulcanius, mathematics under Snell, and other branches of learning under other able professors. At the age of twenty, he published a Latin panegyric on Maurice prince of Nassau. After having taken the degrees of master of arts, and doctor of philosophy, he applied himself to the study of divinity and the Hebrew language under Gomarus and Trelcatius. From his father he inherited a library well stored with books of divinity and ecclesiastical history ; and at an early period of his life, he acquired a very extensive knowledge in both departments.

At the age of twenty-two, he was appointed director of the College of Dordrecht. In 1602 he married Elizabeth Corput, the daughter of a minister. After bearing three children, she died on the 6th of February 1607 ; and on the 18th of August ensuing, he married Elizabeth du Jon, the daughter of an eminent theologian, better known by his Latinized name of Junius. By this second marriage, he had five sons and two daughters, but he had the misfortune to survive all his children except one son. In 1614 he was appointed director of the Theological College established at Leyden ; but in 1618, he relinquished this office for the professorship of eloquence and of chronology. Vossius, whose sentiments were moderate and peaceful, was anxious to shun the theological strife which at that time agitated the Dutch republic. But his *Historia Pelagiana*, published in 1618, involved him in some trials and difficulties. In that elaborate work, he discussed the doctrine of predestination and grace in a strain which the Calvinists considered as much too favourable to the tenets of Arminius. In 1620 the synod of Tergou deprived him of his professorship ; but another synod, held at Rotterdam in the following year, permitted him to be reinstated, under the condition of his retracting the errors contained in his history, and promising neither to do nor say any thing in opposition to the decrees of the synod of Dordrecht. These he doubtless considered as very hard terms, and for some years he declined to comply with them. In the mean time he was prohibited from teaching either in public or in private ; and in one of his letters, he estimates his pecuniary loss at six thousand livres a-year. In 1624 he made such concessions or explanations as led to his reinstatement.

What exposed him to persecution at home, recommended him to favour abroad. Archbishop Laud, a very zealous patron of Arminianism, was so highly satisfied with his work, that he procured him a prebend at Canterbury, which he was permitted to hold as a mere sinecure. He proceeded to England in 1629, and was installed. On paying a visit to Oxford, he was created LL. D. Here he discovered and encouraged the talents of Dr Pocock, who became so eminent as an orientalist. A college or Athenæum having been founded at Amsterdam, Vossius was appointed professor of history in the year 1633. Here he continued his learned labours till the time of his death, and produced a variety of works, distinguished by the extent and solidity of their erudition. He died on the 19th of March 1649, at the age of seventy-two.

He was highly esteemed by his contemporaries for his moral worth, as well as for his talents and learning. He was not only an able grammarian and critic, but was likewise skilled in history and theology. He has written treatises on history, poetry, rhetoric, logic, and the mathematical sciences. His work entitled " Aristarchus, sive de Arte Grammatica," is not only very elaborate, but likewise very able and judicious. An edition of it is now printing at Halle under the superintendence of Förtsch. In this department, we must not overlook his " Etymologicon Linguæ Latinæ," and his work "De Vitiis Sermonis." His "Institutiones Oratoriæ," are also very elaborate. His "Ars Historica," and his treatises "De Historicis Græcis," and "De Historicis Latinis," are valuable specimens of his labours as a professor of history; and the last of them is still held in much estimation. In the nine books "De Idololatria," he displays the same unlimited research that characterises all his larger works. Of his theological learning he has exhibited no mean specimen in his "Historiæ de Controversiis quas Pelagius ejusque Reliquiæ moverunt, libri septem." Of the entire works of Vossius, a great treasure of erudition, a complete collection was published at Amsterdam in 1701, in six volumes folio.

Vossius had five sons, who were all known by their literary productions. Their names were Dionysius, Francis, Gerard, Matthew, and Isaac. The last was the only one who survived him.

Vossius, *Isaac*, the son of this learned and estimable man, was born at Leyden in the year 1618. He was trained under the domestic superintendence of his father, and became one of the most learned men of his own age. In 1639, when he had only reached his twenty-first year, he distinguished himself by an edition of the Periplus of Scylax. In 1642 he made a journey to Italy, and visited Rome. He became one of the literary correspondents of the queen of Sweden, and, like some other scholars of eminence, was invited to her court. It appears from his letters, that he was at Stockholm in 1649, 1650, and 1651. His misunderstanding with Salmasius however exposed him to the queen's displeasure; and in 1652, when he returned from Holland, accompanied by Bochart and Huet, he was not admitted to her presence. But she soon renewed her correspondence with Vossius, and saw him during her visit to Holland. On the death of his father, he was offered the professorship of history at Amsterdam; but he preferred a life of studious retirement, and he appears to have been sufficiently independent to follow the bent of his own inclination. In 1663 he received a handsome present from Louis the Fourteenth. In 1670 he came to England; and having visited Oxford during the same year, he was created LL. D., and, as Wood states, was "with great humanity and friendship entertained by some of the chief heads of houses, as his father had been before in 1629." He had now acquired a high reputation; and in 1673 the king bestowed upon him a canonry of Windsor. Both he and his father must have held their preferments as lay-sinecures. He died in Windsor Castle on the 10th of February 1689, in the seventy-first year of his age. On his death-bed, he was visited by the dean of Windsor and one of the canons, who urged him, but in vain, to take the sacrament. "Dr Vossius, if you will not do it for the love of God, at least do it for the honour of the chapter." This appeal was ineffectual; and to one of the dean's pious admonitions, he replied, "I wish you would instruct me how to oblige the farmers to pay me what they owe me: that is what I would have you to do for me at present." King Charles sometimes observed, that there was nothing which he refused to believe, except the Bible. Some of his works indeed display sufficient credulity. Of this we find abundant evidence in his "Variarum Observationum liber," in which he avers that ancient Rome was twenty times as large as Paris and London together, and estimates its population at fourteen millions. Of the population of China, he has given an account still more extravagant. His judgment is on most occasions greatly inferior to his learning, and the spirit of paradox very seldom deserts him. In his usual strain, he wrote various tracts on the Septuagint, and was opposed by Father Simon and Dr Hody. On the age of the world he maintained with Hornius a controversy which involved the chronology of this version. Another curious work he published, "De Sibyllinis aliisque quæ Christi natalem præcessere Oraculis." Oxon. 1680, 8vo. This is the second edition. One of his most able and pleasing works is entitled "De Poematum Cantu, et Viribus Rythmi." Oxon. 1683, 8vo. Among other ancient authors, he published editions of Catullus and Pomponius Mela, which, if he had produced no original work, would have been sufficient to recommend him to the notice of posterity as a man of uncommon erudition. (X.)

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors.

VOURLA, a sea port of Asia Minor, on the site of the ancient Clazomene, one of the twelve great cities of Ionia. It is built on two eminences; and one division is inhabited by Christians, who occupy about 500 houses, and possess two churches; the remainder of the town is inhabited by Turks. It is now of little importance. Vourla is twenty-five miles west of Smyrna.

VOW, a solemn religious promise or oath. The use of vows is found in most religions. They form a considerable part of the Pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprize. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow in any thing lawful and possible, he was obliged to fulfil it. If he appointed no particular time for accomplishing his vow, he was bound to do it instantly, lest by delay he should prove less able, or be unwilling to execute his promise. Among the papists, a person is constituted a religious by taking three vows, that of poverty, chastity, and obedience. Vows among the Romans, signified sacrifices, offerings, presents, and prayers made for the Cæsars, and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every five years, then every fifteen, and afterwards every twenty, and were called *quinquennalia*, *decennalia*, and *vicennalia*.

VOWEL, in *Grammar*, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard and to form a distinct voice. The English vowels are six in number, viz., A, E, I, O, U, Y.

VUKOVAR, a market town, the capital of a district of the same name in the Sclavonian province of Hungary. It stands on the river Danube, and contains 700 houses, and 5820 inhabitants. Lat. 45. N. Long. 19. E.

VULCAN, in Pagan worship the god of subterraneous fire and metals, was the son of Jupiter and Juno; and was said to be so remarkably deformed, that his father threw him down from heaven to the isle of Lemnos, in which fall he broke his leg, and there he set up his forge, and taught men how to soften and polish brass and iron. Thence he removed to the Liparian isles, near Sicily, where, by the assistance of the Cyclops, he made Jupiter's thunderbolts, and armour for the other gods. Notwithstanding the deformity of his person, he had a passion for Minerva, and by Jupiter's consent paid his addresses to her, but without success. He was however more fortunate in his suit to Venus; but after their marriage she chose Mars for her gallant, and Vulcan exposed them to the ridicule of the other gods, by taking them in a net.

VULCANO, one of the Lipari islands in the Mediterranean sea, to the south of the principal island. It is a lofty island about fifteen miles in circuit, and possesses two small ports on its northern coast, where Valcanello is joined to it by a low rock formed of its own lava. Long. 14. 55. 56. E. Lat. 38. 23. 19. N.

VULGATE, a very ancient Latin translation of the Bible, and the only one acknowledged by the church of Rome to be authentic.

W.

W, or w, is the twenty-second letter of our alphabet; and is composed, as its name implies, of two v's. It is not in use among the Hebrews, Greeks, or Romans, but chiefly among the northern nations, the Teutones, Sax ns, Britons, &c. It is not employed by the French, Ital ns, Spaniards, or Portuguese, except in proper names, and ther terms borrowed from languages in which it is orig ally used, and even then it is sounded like the single v. This letter is of an ambiguous nature; being a consonan at the beginning of words, and a vowel at the end. It ma stand before all the vowels except *u;* as *water*, *wedge*, *win r*, *wonder:* it may also follow the vowels *a*, *e*, *o*, and uni s with them into a kind of double vowel, or diphthong; as i *saw*, *few*, *cow*. It also goes before *r*, and follows *s* and *th;* in *wrath*, *swear*, *thwart:* it goes before *h* also, though in r lity it is sounded after it; as in *when*, *what*. In some wor it is obscure, as in *shadow*, *widow*.

AAG, a river of Hungary, which rises in the Carpathi Mountains, and falls into the Danube opposite to the isla of Sehut.

AAL, a river of the Netherlands, being one of the bra hes of the Rhine. Running from east to west through Gu lerland, passing by Nimeguen, Tiel, Bommel, and Go um, and uniting with the Maes, it falls into the Germa Sea below the Briel.

ADEY Abassi, a small river of Arabia, which falls int he Red Sea ten miles south-south-east of Hodeida.

ADEY *el Arkik*, a small river of Arabia, which waters the ty of Medina.

ADEY *el Kebir*, a small river in Arabia, which in rainy sea ns reaches the Red Sea near Mocha.

ADEY *Elmahan*, a small river of Arabia, which loses its in the sands, unless in the wet season, when it reaches the ed Sea twenty-five miles south-south-east of Hodeida.

ADEY *Faran*, a small river of Arabia, which falls into the ed Sea twenty-five miles north-west of Tor.

ADEY *Zebid*, a river of Arabia, which passes by Zebid, and t a particular season overflows and fertilizes its banks. It lly loses itself in the sands.

ADJO, or Waju, a state or confederacy in the island of lebes, situated to the north of the Buggess territories nar l Boni.

AFERS, or *Sealing Wafers*, are made thus. Take very fin lour, mix it with glair of eggs, isinglass, and a little yea ; mingle the materials; beat them well together; spread the atter, being made thin with gum-water, on even tin pla , and dry them in a stove; then cut them out for use. Yo may make them of what colour you please, by tinging the aste with Brazil or vermilion for red; indigo or verditer, &c. or blue; saffron, turmeric, or gamboge, &c., for yellow.

AFTIB, a small low island in the Eastern Seas, on the est coast of the island of Waygiou, covered with tre

AGEEO, or Waygiou, one of the Papuan islands, sep ated by Dampier's Strait from New Guinea to the sou . It may be estimated in length at ninety miles, by enty-two miles in average breadth. The island is thr ghout mountainous at a small distance from the coast, an very woody, being covered with an immense forest rea ing to the water's edge. The trees grow to an imme e height; and vegetables are in great variety, namely, ora es, cocoa-nuts, sugar-canes, sago, and pimento. On the orth coast of this island is a harbour formed by the island of Rawak, on which grows the ambong tree, the heart of which is an excellent cabbage. On the north-west coast of Waygiou there is another harbour named Piapis, situated in latitude 0° 5′ south, long 130° 15′ east. It is formed by two capacious bays, where there is fresh water, and abundance of tall timber fit for masts. Both bays have good mud soundings; and on a small island named Sisipa is a pond of fresh water, with sago trees growing close to it. Here the cabbage tree also abounds. The gigantic Kima cockle is found in plenty among the coral reefs. Turtles of large size are found on the shore, and numbers of wild hogs in the woods. Here are seen many rare and beautiful birds, namely, the black cockatoo, the bird of paradise, &c. The natives are of a very suspicious disposition, probably from their being trepanned as slaves. They are barbarous in their habits, going almost entirely naked. The chiefs only have jackets and trousers of Chinese stuffs, and wear a hat and turban. The colour of their skins is not black; their hair is thick and curled, and grows to a considerable length. Their houses, which are built on posts, consist of bamboo, and are elevated above the ground. The aborigines inhabit the interior, the Mahommedans the sea-coast. The island is situated about the 131st degree of east longitude, and within the 12th degree of south latitude.

WAGES. See Taxation.

WAGGON, a wheel-carriage, of which there are various forms, accommodated to the different uses for which they are intended. The common waggon consists of the shafts or rods, being the two pieces which the hind horse bears up; the welds; the slotes, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn in wheeling the waggon across the road; the chest or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops which compose the top; the tilt, the place covered with cloth, at the end of the waggon. See Mechanics.

WAGNAGUR, a town of Hindustan, possessed by independent native chiefs, on the sea-coast of the Gujerat peninsula. Long. 71. 58. E. Lat. 21. 3. N.

WAGUR, a district of Hindustan, in the province of Cutch, of which it forms the eastern boundary. The inhabitants are Mahommedans, and predatory in their habits; and the country is elevated and woody, and intersected by a number of streams which fall into the Runn.

WAHI, a town of Hindustan, in the province of Bejapoor, long the residence of an illustrious Mahratta family, about fifty miles south of Poonah.

WAIFS, Bona Waviata, are goods stolen, and waived or thrown away by the thief in his flight, for fear of being apprehended. These by the law are given to the king, as a punishment upon the owner for not himself pursuing the felon, and taking away his goods from him. And therefore if the party robbed do his diligence immediately to follow and apprehend the thief (which is called *making fresh suit*), or convict him afterwards, or procure evidence to convict him, he shall have his goods again.

WAIGATZ, a large island belonging to the Russian government of Archangel. It is situated between 69° 20′ and 70° 5′ north latitude, and between 47° 20′ and 50° 13′ east longitude. It is separated from the mainland by the straits of its name. It is low, stony, destitute of woods, and almost of vegetation; but being well stocked with wild animals, especially such as yield valuable furs, it is inhabited by some families, who are almost exclusively occupied in their chase and destruction. Its shores abound in fish; and immense flocks of birds frequent the island, whose feathers are of considerable value, and in pursuit of which many persons repair to the island in the appropriate season. To the south-west of this large island are three others, called Malvijef, Dolgoi, and Bilinov, whose products are of a similar kind.

WAIGATZ *Straits*, situated between Nova Zembla and Russia, through which the Dutch sailed to the north, as high as 75°, in order to discover a north-east passage to China and the East Indies.

WAINFLEET, a market-town in the Lindsey division of the county of Lincoln, in the hundred of Candelshoe, 132 miles from London. It is situated on a creek of the sea, only navigable for small vessels. The town comprehends two parishes, All Saints and St Mary's, with each a church. There is a weekly market on Saturday, and three annual fairs. The population amounted in 1821 to 1422, and in 1831 to 1795.

WAINSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in panels, and painted, to serve instead of hangings.

WAKE, the track impressed by the course of a ship on the surface of the water. It is formed by the re-union of the body of water which was separated by the ship's bottom while moving through it; and may be seen to a considerable distance behind the stern, as smoother than the rest of the sea. Hence it is usually observed by the compass, to discover the angle of lee-way. A ship is said to be in the wake of another when she follows her on the same track, or a line supposed to be formed on the continuation of her keel. Two distant objects observed at sea are called in the wake of each other, when the view of the farthest is intercepted by the nearest, so that the observer's eye and the two objects are all placed upon the same right line.

WAKEFIELD, a large market-town of the wapentake of Morley, in the west riding of the county of York, 180 miles from London and nine from Leeds. It stands on the river Calder, is well built, with wide streets, in which are many very handsome brick houses. Besides the churches, the other public buildings are, the free grammar-school, the house of correction for the county, the cloth-hall, and a theatre. The chief trade of this town formerly was the manufacture of woollen cloths, and at one period the clothing for the Russian army was fabricated here; but that branch has been lost, and the other branches of the woollen trade have not advanced at the same pace as in Leeds and other neighbouring towns. Wakefield has now the largest corn-market in England next to London. The corn is brought mostly by canals from the south-east part of the county, and the foreign corn from Hull, which is chiefly used by the densely peopled districts near Leeds, Halifax, Huddersfield, and Barnsley, with all of which places there is a water-communication. The corn-market is on Friday, and there is one for wool on Thursday. The quarter-sessions for the west riding are held here. There is also a weekly petty-session. The population amounted in 1801 to 8131, in 1811 to 8593, in 1821 to 10,764, and in 1831 to 12,232. This is one of the new boroughs created by the reform act of 1832, and returns one member to the House of Commons.

WAKEFIELD, GILBERT, a commentator and critic of some celebrity, born at Nottingham on the 22d of February 1756, was the son of the Rev. George Wakefield, rector of the parish of St Nicolas. He was observed in his earliest infancy to be of a serious turn of mind, and he made a rapid progress in the first elements of literature. At the age of seven, he was sent to a free school at Nottingham, and remained there two years, chiefly under the tuition of Mr Beardmore, afterwards master of the Charterhouse: he was then sent to a school kept by the Rev. S. Pickthall, at Wilford, an institution which seems to have been only distinguished by the regular imprisonment of the boys for no less than eleven hours a day. After this, when his father obtained the vicarage of Kingston in Surrey, with the chapelry of Richmond, he was placed under the care of his curate, who kept a school at Richmond; he was, however, removed in 1769 to a better conducted establishment in the same neighbourhood, kept by the Rev. R. Wooddeson, of whom he speaks in his Memoirs with high approbation.

At sixteen he went to Jesus College, Cambridge, where his classical studies still continued to be the principal object of his attention, although he was so fortunate as to obtain the rank of second wrangler at the termination of his academical studies in 1776. He has indeed the candour to observe, that the year was below mediocrity with regard to the performances of the candidates in general; and that, when he obtained the second classical medal, on the Duke of Newcastle's foundation, he had only one competitor. Still it must not be denied, that to be both second wrangler and second medallist in any year implies no ordinary portion of application, as well as some considerable talent. Mr Wakefield was however distinguished, throughout his life, by a singular mixture of opposite habits; and, in the midst of his studies, he confesses that "he sometimes felt himself almost incapable of reading a single page for months together;" and in summer especially, he could only wander about the fields in a state of perfect inactivity. On the other hand, he says that, "for five years he rose, almost without exception, by five o'clock, winter and summer, but never breakfasted, drank tea, or *supt* [supped]," or of course dined, "alone half a dozen times during all that space, enjoying society, from the first, beyond measure."

He became a fellow of Jesus College in 1776, and he gained, in two successive years, the second bachelor's prizes given by the chancellor. In 1778 he was ordained by the bishop of Peterborough, though he did not subscribe the articles without great reluctance. He obtained a curacy first at Stockport in Cheshire, and then at Liverpool. The year after, he married Miss Watson, a niece of the rector of Stockport, and thus vacated his fellowship. His domestic life appears to have been happy and harmonious, though the only merit of his wife, that he has left upon record, is the singular hereditary qualification, that her great-grandfather and great-grandmother had lived together as ma and wife for seventy-five years. Soon after his marriage he became classical tutor in the dissenting academy at Warrington, though he did not professedly unite with any specific community of dissenters as adopting all thei opinions; but he soon began openly to attack those o the established church, in a multitude of controversia writings, and especially in the notes accompanying hi new translations of some parts of the Scriptures; a work for which he had diligently laboured to prepare himself b the study of various dialects of the oriental language After the dissolution of the academy of Warrington, h lived at Bramcote in Nottinghamshire, at Richmond, an at Nottingham; partly occupied in the instruction of a fe pupils, and partly in pursuing his own studies and illustrations of antiquity. In 1786, and for two or three year after, he suffered greatly from an acute pain in his shoulde which interfered materially with the prosecution of his theological investigations.

In the year 1790, he accepted the classical professorshi at Hackney. Here his lectures and instructions were generally approved and admired, but he carried his disse from the articles of faith of any established society Christians so much farther than any of his colleagues, th he was thought too independent to continue in his situatio and he consequently left the institution in 1791; and for sim r reason he failed of obtaining the charge of two privat pupils whom he expected to have been placed with him He continued to reside at Hackney, employing himself artly as an author and editor, and partly in the education f his own children. Among his original productions wer several polemical and political pamphlets, relating to the ar with France, and to the various controversies of the ay. Of these the most remarkable for its consequences to nself was his Reply to the Bishop of Landaff's Addre which occasioned a prosecution to be brought by the att ey-general, against his publisher first, and then against him lf; and he was sentenced to be confined for two years in rchester jail; a punishment which was probably inten d to be somewhat severe, but which was most fortunat in its operation on his subsequent comfort, since it was e cause of his obtaining, by the exertions of his friends and is partisans at large, a subscription of about L.5000; a su which not only alleviated the rigour of his imprisonmen but also enabled him to leave his family in a state of mparative affluence.

H was principally occupied during his confinement in con uing his literary labours for the press, and in prepar g a series of classical lectures, beginning with the illust tion of the second book of Virgil's Æneid, the first cou e of which he delivered in London immediately after his eration in May 1801. The effect of unusual exertions of ly and mind, after so long a cessation of exercise, and in t summer weather, appears to have predisposed his con tution to a typhus fever, of which he died, after a fort ght's illness, on the 9th of September 1801, leaving a wid and six children, four sons and two daughters. His bro er, the Rev. Thomas Wakefield of Richmond, also sur ed him, and died in 1806. The catalogue of his litera offspring is so multitudinous, that it partly tells its own sto by its length, and admits of very few particular rema s.

1 Poemata; quibus accedunt quædam in Horatium Obser iones. Cantab. 1776, 4to.

33. A Reply to Paine's second Part of the Age of Reason. Lond. 1795, 8vo.

34. Poetical Translations. Lond. 1795, 12mo. Especially from Horace and Juvenal.

35. Bionis et Moschi quæ supersunt. Lond. 1795, 12mo.

36. Virgilii Opera. Lond. 1796, 12mo.

37. Observations on Pope. Lond. 1796, 8vo.

38. A Reply to the Letter of Edmund Burke, Esq. Lond. 1796, 8vo. Twice reprinted.

39. Homer's Iliad by Pope, with Notes. Lond. 1796, 11 vols. 8vo.

40. Lucretius de Rerum Natura. Lond. 1796–7, 3 vols. 4to and 8vo. A splendid book, with some collations of manuscripts, and some notes of Bentley. But the collations are said to be inaccurate, and the commentary more prolix than judicious. See Porson in Br. Critic, 1801, xvii. p. 452, and Elmsley in the Classical Journal. He received however many grateful panegyrical acknowledgments from his German correspondents. The edition is dedicated to Mr Fox, with whom he commenced an acquaintance on the occasion.

41. In Euripidis Hecubam Diatribe. Lond. 1797, 8vo. On Porson's Hecuba.

42. A Letter to Jacob Bryant, Esq. on the War of Troy. Lond. 1797, 4to.

43. A Letter to William Wilberforce, Esq. Lond. 1797, 8vo. Reprinted.

44. A Reply to some parts of the Bishop of Landaff's Address to the People of Great Britain. Lond. 1798, 8vo. Twice Reprinted.

45. A Letter to Sir John Scott, his Majesty's Attorney General, on the subject of a late Trial. Lond. 1798, 8vo.

46. Defence delivered in the Court of King's Bench. 47. Address to the Judges in April. 48. Address to the Judges in May. Printed, but not published.

49. The first Satire of Juvenal Imitated. 1800, 12mo. Life, vol. ii.

50. Correspondence with the late Right Hon. C. J. Fox. Lond. 1813, 8vo. Chiefly on subjects of Classical Literature.

But few of the characters that have ever employed the pen of a biographer have exhibited more remarkable con-

Wakefield.

trasts, either in a moral or a literary point of view, than that of Gilbert Wakefield; and he has accordingly been depicted, by critics and historians of various sentiments, in colours the most opposite and the most discordant. "Of his particular modes of thinking on religious and political subjects," says Dr Lindsay, "different men will form different opinions: concerning the integrity of his heart, and the consistency of his character, there can be but one opinion amongst those who enjoyed the happiness of his acquaintance." It would indeed be difficult to find a more splendid example of high honour and self-denial, and of magnificent liberality, even under actual pecuniary embarrassment, than Mr Wakefield displayed, at a time when he had to support himself, with a wife and six or seven children, on about L.150 a year, in voluntarily paying the expenses of Mr Cuthell on his prosecution for publishing the Reply to the Bishop of Landaff's Address, which exceeded the whole yearly amount of his income. "His devotedness to study," says his friend Dr Aikin, "was by no means attended with a reserved or unsocial disposition; for no one could delight more in free conversation, or bear his part in it with a more truly social spirit; and if, in controversial and critical writings, he was apt to indulge in the contemptuous and severe expressions which he found too much sanctioned by polemical use, in disputation by word of mouth he was singularly calm and gentle, patient in hearing, and placid in replying. To conclude the topic of [his] moral character, it was marked by an openness, a simplicity, a good faith, an affectionate ardour, a noble elevation of soul, which made way to the hearts of all who nearly approached him, and rendered him the object of their warmest attachment." But "he wanted time or patience," says Dr Parr very justly, "for that discrimination which would have made his conjectures fewer indeed but more probable, and his principles more exact: [yet] I shall ever think of him as one of the best scholars produced by my own country in my own age." The compliments of Heyne, and of his pupil Jacobs, are still more elaborate; but it is well known, that when Porson was one day asked for a toast, with a sentiment from Shakspeare, he gave "Gilbert Wakefield, *What's Hecuba to him, or he to Hecuba?*" and there was quite as much of truth as there was of neatness in the application. A reviewer of his Life in the British Critic, by no means favourably disposed towards him, readily admits that "he was strictly and enthusiastically honest, and seems to have acquired even a passion for privations: these feelings, added to his pride of independent thinking, led him, we doubt not," he says, "to abstain from wine; to have relinquished in part, and to be tending entirely to give up, the use of animal food, with various other instances of peculiarity. Knowing his own assiduity, and giving himself ample credit for sagacity, he thought that he was equal to the decision of every possible question: and thus he became bigoted to almost every paradox which had once possessed his very eccentric understanding. He was as violent against Greek accents as he was against the Trinity, and anathematized the final N as strongly as episcopacy. Whatever coincided not with his ideas of rectitude, justice, elegance, or whatever else it might be, was to give way at once, and to be rescinded at his pleasure, on pain of the most violent reprehension to all opponents; whether it were an article of faith, a principle of policy, a doctrine of morality, or a reading in an ancient author, away it must go, *κύνεσσιν οἰωνοισί τε πᾶσι*, to the dogs and the vultures. These exterminating sentences were also given with such precipitancy, as not to allow even a minute for consideration. To the paper, to the press, to the [public], all was given at once, frequently to the incurring of the most palpable absurdity. Thus the simple elegance of *O beatĕ Sexti*, in Horace, was proposed, in an edition of that author, to be changed to *O bea Tē Sexti*, though the alteration, besides being most bald and tasteless, produced a blunder in quantity so gross, that no boy, even in the middle part of a public school, would have been thought pardonable in committing it. By faults [either] original or habitual, his sincerity became offensive, his honesty haughty and uncharitable, his intrepidity factious, his acuteness delusive, and his memory, assisted by much diligence, a vast weapon which his judgment was totally unable to wield."

It is not impossible that Mr Wakefield might have been more successful in his studies, if he could have found sufficient motives for directing them rather to scientific than to philological pursuits; for he seems to have been fully impressed with the superior dignity of science to that of any department of philology. "Compared with the noble theories of mathematical philosophy," he says, "our *classical* lucubrations are as the glimmering of a taper to the meridian splendour of an equatorial sun." He would, however, scarcely have had perseverance enough to distinguish himself in that solitary labour which is required for the minute investigation of natural phenomena: and it is seldom that any collateral encouragement is held out, in this country, for the continued cultivation of abstract science; while the classical scholar, though he is supposed to be principally occupied with nouns, and verbs, and particles, is, in fact unconsciously, and therefore most effectually, learning the arts of poetry, and rhetoric, and logic, which have furnished in all ages, the spur and the reins for urging on and directing the mighty bulk of the body politic, in church and in state, at the will of its leaders. The young man, on the other hand, who commences the pursuit of science with ardour, obtains, if he is most successful, and untormented by unnecessary scruples, a quiet fellowship, a comfortable apartment, and an excellent plain dinner for the remainder of his life; and if he fails of these, he may chance to be made an exciseman; or, in the improved arrangements o the present auspicious days, a computer or an assistant astronomer; but with respect to any influence that his pursuits might be supposed to have on the elevation of his rank in life, or in the independent provision for a family, he mus lay no such flattering unction to his soul, but must at al times place his pride and his happiness in the reflection tha *at mihi plaudo ipse domi*, which is, in truth, the best sublunary support of the wise and the good in every circumstance of human life. (L. L.)

akes.

WAKES. Mr Whitaker, in his History of Manchester has given a particular account of the origin of wakes and fairs. He observes, that every church at its consecration received the name of some particular saint; that this custom was practised among the Roman Britons, and continued among the Saxons; and that in the council of Cealchythe, in 816, the name of the denominating saint was expressly required to be inscribed on the altars, and also on the wall of the church, or a tablet within it. The feast of this sain became of course the festival of the church. Thus Christian festivals were substituted in the room of the idolatrou anniversaries of heathenism. Accordingly, at the first introduction of Christianity among the Jutes of Kent, Pop Gregory the Great advised, what had been previously don among the Britons, viz. Christian festivals to be instituted in the room of the idolatrous, and the suffering da of the martyr whose relics were reposited in the church, o the day on which the building was actually dedicated, to b the established feast of the parish. Both were appointed and observed; and at first they were clearly distinguished among the Saxons, as appears from the laws of the Confessor, where the *dies dedicationis*, or *dedicatio*, is repeatedl discriminated from the *propria festivitas sancti*, or *celebrati sancti*. They remained equally distinct till the Reformation. In 1536 the dedication-day was ordered for the future to be kept on the first Sunday in October, and th festival of the patron saint to be celebrated no longer. Th lat r was, by way of pre-eminence, denominated the *church's* ho day, or its peculiar festival; and while this remains in ma y parishes at present, the other is so utterly annihilated in d, that Bishop Kennet, says Mr Whitaker, knew nothing of s distinct existence, and has attributed to the day of de cation what is true only concerning the saint's day. Th s instituted at first, the day of the tutelar saint was ob rved, most probably by the Britons, and certainly by th Saxons, with great devotion. And the evening before ev y saint's day, in the Saxon Jewish method of reckoning th hours, being an actual hour of the day, and therefore, lik that, appropriated to the duties of public religion, as th reckoned Sunday from the first to commence at the su et of Saturday, the evening preceding the church's holid would be observed with all the devotion of the festival. Th people actually repaired to the church, and joined in th services of it; and they thus spent the evening of their gr ter festivities, in the monasteries of the north, as early as e conclusion of the seventh century.

hese services were naturally denominated, from their la hours, *wæcan* or *wakes*, and *vigils* or *eves*. That of the an versary at Ripon, as early as the commencement of the ei th century, is expressly denominated the *vigil*. But th of the church's holiday was named *cyric wæcan*, or ch ch-wake, the church-vigil, or church-eve. And it was th commencement of both with a wake, which has now ca ed the days to be generally preceded with vigils, and th church-holiday particularly to be denominated the *ch ch-wake.* So religiously were the eve and festival of th patron saint observed for many ages by the Saxons, even as te as the reign of Edgar, the former being spent in the ch ch, and employed in prayer. And the wakes, and all th other holidays in the year, were put upon the same footin with the octaves of Christmas, Easter, and of Pentecost. W en Gregory recommended the festival of the patron sa t, he advised the people to erect booths of branches ab t the church on the day of the festival, and to feast and be merry in them with innocence. Accordingly, in every pa sh, on the returning anniversary of the saint, little pavili s were constructed of boughs, and the people indulged in hem to hospitality and mirth. The feasting of the saint's da however, was soon abused; and even in the body of th church, when the people were assembled for devotion, th began to mind diversions, and to introduce drinking. T growing intemperance gradually stained the service of t vigil, till the festivity of it was converted, as it now is, in the rigour of a fast. At length they too justly scandali d the Puritans of the seventeenth century, and numbers o he wakes were disused entirely, especially in the east a some western parts of England; but they are commonly o erved in the north, and in the midland counties.

his custom of celebrity in the neighbourhood of the c rch, on the days of particular saints, was introduced into E gland from the continent, and must have been familiar e ally to the Britons and Saxons; being observed among t churches of Asia in the sixth century, and by those o he west of Europe in the seventh. And equally in Asia a Europe, on the continent and in the islands, those celeb ies were the causes of those commercial marts which we d ominate *fairs.* The people resorted in crowds to the f ival, and a considerable provision would be wanted for t r entertainment. The prospect of interest invited the li e traders of the country to come and offer their wares; a thus among the many pavilions for hospitality in the n ghbourhood of the church, various booths were erected f the sale of different commodities. In larger towns, surr nded with populous districts, the resort of the people to t wakes would be great, and the attendance of traders n nerous; and this resort and attendance constitute a fair. B sil expressly mentions the numerous appearance of traders a hese festivals in Asia, and Gregory notes the same custom to be common in Europe. And as the festival was observed on a feria or holiday, it naturally assumed to itself, and as naturally communicated to the mart, the appellation of *feria* or fair. Indeed several of our most ancient fairs appear to have been usually held, and have been continued to our time, on the original church-holidays of the place: besides, it is observable, that fairs were generally kept in church-yards, and even in the churches, and also on Sundays, till the indecency and scandal were so great as to need reformation.

Walachia.

WALACHIA, a principality situated between the Danube, the Moldau, and the Hungarian province of Siebenbürgen, the capital of which is Bucharest. In the time of the Romans it was a part of Dacia. In the twelfth and thirteenth centuries, it received from the court of Byzantium princes who were tributary to it. After the fall of that government, Walachia became dependent first on Hungary and afterwards on Poland, which was the period of its greatest prosperity; but it terminated in 1421, when the country submitted to the Turks. This submission was voluntary; and in return the princes nominated from Constantinople were allowed to enjoy their ancient constitution, religion, and privileges. These grants however benefited only the princes or hospodars, and the nobility or bojares; for the peasants and the rest of the inhabitants were retained in a state of severe feudal slavery. In consequence of this aristocratical oppression under the hospodars and bojares, the country rapidly declined both in numbers and in cultivation. Those who obtained power paid large sums for it at Constantinople, and extorted from the inhabitants the means of reimbursement during their temporary and dependent exercise of sovereignty. During this period, the Turks retained in their own hands Brahilow, Giurgewo, and Thurnut, the strong places which protect the navigation of the Danube.

In 1716 the first Greek was appointed hospodar; his name was Nicholas Maurokordatus. When he attained the sovereign power, the country was in the most depressed condition, the larger portion of the land uncultivated, and the people almost in a state of savage ignorance. Though no degree of freedom was introduced by the accession of a Greek prince, yet many improvements were introduced which advanced civilization. By this prince a printing-press was established, and some schools founded, in which the ancient Greek and Latin languages were taught, as well as the Sclavonic. Under his brother and successor Constantine, the peasants were lightened of a great part of their slavish burdens. He introduced a better course of agriculture, and first brought in the cultivation of maize, which has gradually become the chief aliment of the people. His successor caused the Bible and the liturgical books of the Greek church to be translated into the vernacular language. The hospodars Alexander Ypsilante, Ghika, Kallimachi, and Karadza, attended to education, or affected to do so, and during their rule books embodying the ancient laws were printed and generally circulated. As the rulers however had unlimited power, subject only to the payment of an annual sum of 300,000 thalers, great oppression, and frequently great cruelty, were exercised towards all under their authority. These hospodars were sometimes suddenly deposed, and in some cases suffered violent deaths, under charges of treachery, which commonly consisted of negociations, real or pretended, with Russia or with Austria. After wars between Turkey and Russia, followed by the successive treaties of Kancardschi, Jassy, and Bucharest, the hospodars were declared to be under the protection of Russia, to which nation the Walachians were much attached, from similarity of religion. When hospodars were appointed, however, the Turkish pacha in command of the fortresses on the Danube put up to auction the revenues paid on the trade by the river, and thus sold a monopoly of the whole commerce in the products of Walachia and Moldavia. This led to great internal distress, which was augmented by the contemporaneous demands made by the bojares or landed proprietors on the peasants. Amidst this unfortunate concurrence of evils, the hospodar Prince Karadza, under apprehension of being deposed, or perhaps of being executed, withdrew himself with his family and his treasure, and passing through Hungary, took refuge in Geneva and Genoa in October 1818. In January 1819, the Porte nominated as his successor Prince Alexander Suzzo, who died two years after. His death seemed to be the signal of a general insurrection, which, though it broke out first in Walachia and Moldavia, speedily extended to the whole of European Greece, as well as to the islands, and produced those transactions which more properly belong to the history of that country than of Walachia.

The insurrection in Walachia was first commenced by a native bojar, Theodore Wladimirsko, who had in the Russian service acquired the reputation of a brave and skilful officer. He had retired from the army, and carried on an extensive trade in corn, by which he had acquired considerable wealth, and had formed connections and obtained confidence among the peasantry and smaller proprietors. The interregnum appeared a favourable moment, and he at first collected fifty adherents in Little Walachia, where he was soon joined by more than 1000 peasants. In the mean time the Porte had nominated a new hospodar, Kallimachi, who sought to form an alliance with Wladimirsko, by means of which he expected to be enabled to raise the sum necessary to be paid at Constantinople as the purchase of his dignity. The negociation was proceeding, and might have been concluded, if not to the honour, to the advantage of the two aspirants; but Alexander Ypsilante, a descendant of him who had been hospodar in 1806, and who had obtained the rank of general in the Russian army, appeared on the scene with a body of Greeks, and took possession of Jassy. This caused a most bloody civil war, by which Walachia and Moldavia were dreadfully ravaged and wasted by alternate victors. The Turks at length sent an army sufficiently strong to suppress the several contending parties, when submission was thus enforced. The sultan, instead of a Greek, nominated a native as viceroy, and in 1822 placed Gregory Ghika on the throne, who, surrounded by Turkish guards, had little or no power, and felt that his dignity was of very uncertain duration. He continued to hold it, such as it was, till 1828, when a new war between Russia and Turkey broke out, and the former took possession of both the principalities, and established in Bucharest a plan of Russian civil organization.

In its present state, Walachia extends in north latitude from 43° 44′ to 46° 17′, and in east longitude from 22° 52′ to 27° 51′, and is in extent 24,640 square miles. It is divided into two portions, viz. Eastern or Little Walachia, and Western or Great Walachia, and these are again subdivided into circles, of which the number in the former is five, and in the latter twelve. In the whole are comprehended twenty-two cities or fortified places, twenty-five market-towns, and 2548 villages and hamlets. The number of the inhabitants is very doubtful; some accounts make them amount to more than 1,000,000, while others state them not to exceed 600,000. Nearly the whole of them adhere rigidly to the Greek church, and are under the ecclesiastical authority of the archbishop of Bucharest, and of the bishops of Rimnik and of Buseo. There are numerous monasteries, but the occupants of them are very few. The people are strict in observing the great number of holidays which the Greek church enjoins, and which are said to exceed 200 in each year, and on which no one works. There are a few Roman Catholics, who own as their suffragan the bishop of Nicopolis. The people are of mixed races, Walachians, Greeks, Armenians, Jews, and Gipsies. The latter, amounting to 50,000 persons, are chiefly employed in the more servile occupations. These mixed rac have formed a common language, composed partly of Gree somewhat more of Latin, and abounding in words of origin derivation. It has been seldom acquired by any foreigne nor has it been much studied or grammatically analysed.

A portion of the Carpathian Mountains, through whic are several passages leading to the Austrian territories, surrounds Walachia on the west and north-west sides. Fro these, mountains project towards the Danube, and betwee them are beautiful and fruitful vales, containing soils capabl of producing most abundant crops. From the termination these spurs from the mountains there is a level district, declining gradually to the great stream, and on its border becoming marshes and morasses, in some parts covered wit wood.

If the inhabitants were industrious, the government protective, many of the holidays abolished, and capital coul be accumulated, few parts of Europe would produce s much of all that contributes to life and comfort as this principality. With its ignorant and inactive occupation, th land yields great crops of maize, wheat, and barley. Th first two are the exclusive food of man, and the latter of th cattle. Hemp and flax are flourishing products. Fruit every kind is plentiful; the sides of the hills are covere with vines, and the wine made from them is equal to tha of Hungary. The land is watered by numerous brooks, an the meadows yield excellent pasture for black cattle, whil there are plains well adapted for the breeding of horses. Th export of horses and cows is the chief trade between th principality and the surrounding countries. The climate i temperate, though colder in winter than in the districts to th south of the Balkan Mountains, but the winter scarcely endures more than two months. There are no mines at work and no manufactures except those of the domestic kind.

WALAJA, or Abadnagur, a town of the south of India in the province of the Carnatic, situated on the north sid of the Palar river. It is a place of considerable consequence, regularly built, rich and populous. By means o bullocks, it carries on a considerable trade between the sea coast and Mysore. Long. 78. 5. E. Lat. 12. 40. N.

WALCHEREN, an island, forming part of the province of Zealand, in the kingdom of Holland. It stands on th north entrance of the western Scheldt, is highly fertile though unhealthy to foreigners, especially in the autumn when they are liable to be attacked by that description o fever which takes its name from the island, and which proved so ruinous to the British army after its capture in 1809. It contains the populous cities of Middleburg and Flushing, and many large villages, and about 33,000 inhabitants.

WALDAI, a circle of the Russian government of Novogorod. It extends in north latitude from 57° 37′ to 58° 16′, and in east longitude from 33° 24′ to 38° 4′, and contains one city and 507 villages, in 100 parishes, with 54,640 inhabitants. It is abundant in streams, and has upwards of 150 small lakes, some of them five or six miles in length. It contains little wood, and the chief pursuit is agriculture. The capital has the same name, a city of 325 inhabitants, 224 miles from St Petersburg. Long. 32. 19. E. Lat. 57. 44. N.

WALDECK, a small principality of the north of Germany, deriving its name from a mountain castle, the ruins of which still exist. It is between 51° 4′ and 51° 31′ of north latitude, and between 8° 26′ and 9° 7′ east longitude, as regards the chief part of the territory; but a small portion of it, the Graffshaft, or county of Pyrmont, is detached from it, and lies between the Prussian and Hanoverian dominions. The entire extent is 480 square miles, or about 307,200 English acres. The whole of Waldeck is a mountainous and woody district, the soil generally is poor and stony, and in the best years scarcely yielding sufficient corn for home consumption, although potatoes form a large portion of the food of the labourers. It has no large rivers, but many small streams, which ultimately fall into the river Weser. In some parts there are large flocks of sheep, which have been improved by mixing with Spanish and Saxon rams, and now produce fine wool. The horned cattle yield abundance of butter and some cheese, which are the only products of the soil that are sent out of the country in exchange for the few foreign luxuries that are needed. The forests abound with game of all kinds, and some of the wild animals, especially the wild hogs, are a great annoyance to the cultivators. The mountain-streams abound in fish, and the trout in them are reported to be of excellent flavour. There are mines of iron and of copper worked, and the proceeds manufactured on the spots where they are drawn. The annual quantity of iron is about 200 tons, that of copper not exceeding forty tons. There are salt springs, which provide the quantity needed of culinary salt; and there are some quarries of good marble. The countship of Pyrmont consists only of a single valley, surrounded on all sides with lofty hills, through which the river Emmer runs, and on its banks are some rich meadows and a few corn-fields. The mineral spring is the great attraction; and accommodations are well provided for the numerous guests that repair to it in search of health. The government of Waldeck is vested in the prince alone, though, on the ancient principle, the states at times assemble, and form a single chamber, at Arolsen, to make laws, but have little business to do. The capital of the principality is a town of 2060 inhabitants. The other towns are Pyrmont, with 4500, and Arolsen, with 17[illegible]. The whole population is 54,000, scattered in ten small towns and 105 villages. They adhere to the Lutheran religion, with the exception of 800 catholics, 600 reformed, and 500 Jews, with a very few quakers. The revenues of the prince amount to about L.40,000, of which L.7000 arises from the water of Pyrmont, and the greater part of the remainder from his landed property; but the revenue is loaded with a heavy debt. At one period the military force was raised to 1700 men, but at present the contingent to the German confederation is 518 men.

WALDEGRAVE Islands, two small rocky islands lying off the southern coast of New Holland. Captain Flinders includes them under the title of the Investigator's Group. Long. of the largest, 134. 44. E. Lat. 33. 35. S.

WALDENSES. See Valdenses.

WALDO. See Valdo.

WALES, a country situated in the south-west part of Britain, into which the ancient Britons retired from the persecution of the Saxons. Anciently it was of greater extent than it is at present, and comprehended all the country beyond the Severn; that is, besides the twelve counties included in it at present, those of Herefordshire and Monmouthshire, which now are reckoned a part of England, were then inhabited by three different tribes of the Britons, namely the Silures, the Dimetæ, and the Ordovices. The Romans were never able to subdue them till the reign of Vespasian, when they were reduced by Julius Frontinus, who placed garrisons in their country to keep them in awe. Though the Saxons made themselves masters of all England, they never could get possession of Wales, except the counties of Monmouth and Hereford. About the year 870, Roderic king of Wales divided his territories among his three sons; and the names of these divisions were, Demetia, or South Wales; Povesia, or Powis-Land; and Venedotia, or North Wales. Another division is afterwards mentioned in the records, viz. North Wales, South Wales, and West Wales; the last comprehending the counties of Monmouth and Hereford. The country derived the name of *Wales*, and the inhabitants that of *Welsh*, from the Saxons, who by those terms denote a country and people to which they are strangers; for the Welsh in their own language call their country *Cymry*, and their language *Cymraeg*. They continued under their own princes and laws from the above-mentioned period, and were never entirely subjected to the crown of England till the reign of Edward I., when Llewellin ap Gryffith, prince of Wales, lost both his life and dominions. Edward, the better to secure his conquest, and to reconcile the Welsh to a foreign yoke, sent his queen to lie in at Caernarvon, where she was delivered of a prince; to whom the Welsh, on that account, the more readily submitted. Ever since that time, the eldest sons of the kings of England have commonly been created princes of Wales, and as such enjoy certain revenues from that country.

Cymru

Cymry is the
Plural for Cymro, whi
means "Welshman". C
Cymru is the Country

Wales is bounded on all sides by the sea and the Severn, except on the east, where it joins to the counties of Chester, Salop, Hereford, and Monmouth. Its length, from the southernmost part of Glamorganshire to the extremity of Flintshire north, is computed at about 113 miles; and its breadth, from the river Wye east to St David's in Pembrokeshire west, is nearly of the same dimensions, being about ninety miles.

After the conquest of Wales by Edward I. very material alterations were made in their laws, so as to reduce them nearer to the English standard, especially in the forms of their judicial proceedings; but they still retained very much of their original polity, particularly their rule of inheritance, viz. that their lands were equally divided among all the issue male, and did not descend to the eldest son alone. By other subsequent statutes their provincial immunities were still further abridged: but the finishing stroke to their dependency was given by the statute 27 Henry VIII. c. 26, which at the same time gave the utmost advancement to their civil prosperity, by admitting them to a thorough communication of laws with the subjects of England. Thus were this brave people gradually conquered into the enjoyment of true liberty; being insensibly put upon the same footing and made fellow-citizens with their conquerors.

It is enacted by 27 Hen. VIII. 1. That the dominions of Wales shall be for ever united to the kingdom of England. 2. That all Welshmen born shall have the same liberties as other king's subjects. 3. That lands in Wales shall be inheritable according to the English tenures and rules of descent. 4. That the laws of England, and no other, shall be used in Wales; besides many other regulations of the police of this principality. And the 34th and 35th Hen. VIII. c. 26, confirms the same, adds further regulations, divides it into twelve shires, and in short reduces it to the same order in which it stands at this day; differing from the kingdom of England in only a few particulars. See England.

WALES, New South. Under this title are included the various British settlements which have been established in the island of New Holland. A description of that island will be found under the article Australasia, together with a short account of its first settlement by the British, and of the early progress of the colony. We now propose to add such further information, and recent statistical details, as will exhibit a view of its progressive increase and its present condition; and to conclude with a short account of the other settlements which have arisen on its western and southern shores, on Swan River, King George's Sound, and more recently at Port Philip.

It was after the separation of the United States from this country that it was first proposed to establish a colony for the reception of convicts from Great Britain on the eastern shore of New South Wales; and in the year 1787 preparations were completed for carrying the design into effect. In 1787 a fleet consisting of eleven sail of ships, including a frigate and an armed tender, and having on board 565 male and 192 female convicts, with 200 troops, and several of their wives and children, set sail from Portsmouth in May; and after a voyage of eight months, in the course of which they touched at Teneriffe, Rio Janeiro, and the Cape of Good Hope, where they spent a month, they arrived at their destination on the 18th, 19th, and 20th of January 1788. Captain Arthur Philip of the royal navy was appointed the first governor of the colony. Botany Bay, where it was proposed to fix the settlement, was found ill adapted for that purpose, being exposed to the fury of the east winds, which roll a tremendous sea on the beach. In seeking for a more eligible situation, Captain Philip entered the inlet to which Cook had given the name of Port Jackson, which he found one of the most capacious and safe harbours in the world, navigable for vessels of any burden fifteen miles from its entrance, indented with numerous coves, sheltered from every wind, and possessing the finest anchorage. Within this harbour, on the shores of Sydney Cove, thinly wooded, and the haunt of the kangaroo, but now marked out as the capital of the future empire, the British ensign was hoisted on the 26th of January 1788. They immediately proceeded to clear the ground, to land the live stock and the stores, and to establish the colony, amounting to 1030 souls. In its early progress the settlers encountered numerous obstacles, which it required extraordinary courage, and perseverance, and untiring industry to overcome. These arose from various causes, from the extremely sterile soil around Sydney Cove, from which no industry could extract a sufficient supply of grain for the wants of the people; from the profligate habits of the convicts, which occasioned continual disorders among themselves; from their outrages on the natives, and the retaliation which these produced. It was some years before an adequate supply of provisions for the maintenance of the colony could be derived from the ungrateful soil. The settlers consequently depended on foreign supplies, which did not arrive, and they experienced the severest privations. The loss of the store-ship the Guardian, under the command of Captain Riou, when proceeding to their relief with a large supply of provisions and stores, was a severe blow to the prosperity of the colony; and the general distress was greatly aggravated by the unseasonable arrival of a convict ship with 222 female convicts on board, thus increasing the number of consumers without any addition to the stock of provisions. The consequence was a severe scarcity, during which the weekly rations were, in April 1790, two and a half pounds of flour, two pounds of rice, and two pounds of pork; the governor sharing equally with others in the common calamity. Even this allowance, barely sufficient for the wants of nature, could not have been afforded if the governor had not sent off upwards of 200 convicts and troops to Norfolk Island, which is about twenty-one miles in circumference, with a fertile soil. Here the settlers, with even smaller allowance than at Sydney, would probably have perished, but for an unlooked-for supply from a flight of aquatic birds alighting on the island to lay their eggs. Owing to the length of their pinions, they take wing with difficulty; and they were so numerous that from 2000 to 3000 were taken every night, besides an incalculable quantity of eggs, which was a seasonable supply, and saved the lives of this detachment from the main body. Every effort was made to obtain supplies from China, India, and the Cape of Good Hope. There were not at one period four months' provisions in the store on the most reduced scale, and several persons had already perished. Shortly after, three other vessels arrived with convicts, a large number of whom perished of the scurvy during the voyage. For about three years the settlers were in danger of starvation, and it was not till June 1790 that relief was afforded, by the arrival of three transports from the Cape; and in the following year a ship of war arrived at Sydney, conveying ten vessels, with 1695 male and 68 female convicts, after losing 198 on the passage. The arrival of this fleet changed the aspect of affairs, and gave the necessary stimulus to the industry of this rising community. Amid the difficulties with which the colony had to struggle, its improvement was not altogether neglected. Cultivation was begun, farms were established at Rose Hill (Paramatta), at other places two towns were commenced, and a few convicts were emancipated, and obtained grants of land as settlers.

Governor Philip embarked for England in December 1792, when Lieutenant-governor Grose succeeded to the government. He was succeeded, on the 15th December 1794, by Captain Paterson; and on the 7th September 1795 Governor Hunter arrived, and immediately entered on his important office. From the year 1792 the improvement of the colony was decisive and rapid. It was in 1789 that the first harvest was reaped at Paramatta; and in 1793 the settlers were enabled to sell corn to the public stores, which was purchased at a given price. Trade began to make its appearance; passage-boats were established between the towns of Sydney and Paramatta, and the settlers visibly increased. The bulls and cows that had been originally brought to the new settlement had, by the carelessness of the keeper, been suffered to stray into the woods, and every subsequent search had proved ineffectual, when a fine and numerous herd of wild cattle was at length discovered in the interior of the country, evidently the progeny of the animals which had been so long lost to the settlers. At the close of the year 1795, the public and private stock of the colony consisted of 57 horses, 227 head of cattle, 1531 sheep, 1427 goats, 1869 hogs, besides a numerous breed of poultry. The total quantity of land in cultivation amounted to 5419 acres. At this period the storehouses were so completely exhausted that, on the arrival of Governor Hunter, there were no salt provisions in store; and the settlement was, as before, reduced to rations. The colony was in danger of falling back; and it was only the speedy arrival of a store-ship at this critical and distressing moment that saved it from destruction in the eighth year of its establishment.[1] At the commencement of the year 1800, the inhabitants had increased to 6000. The stock consisted of 203 horses and mares, 1044 cattle, 1024 sheep, 2182 goats, and 4017 hogs. The quantity of land sown with wheat was 4665 acres, with Indian corn 2930 acres, and with barley 82 acres.

Governor Hunter quitted the colony in the year 1800, and was succeeded by Captain King, who had effected the settlement on Norfolk Island. His administration lasted six years, and was distinguished by what is termed the "Irish rebellion," which broke out about the year 1804. Several hundred convicts attached to the government establishment at Castlehill, about twenty miles from Sydney, struck work and demanded their liberty; having armed themselves with pikes, they prepared for resistance. They were however overthrown after a brief contest by the troops at Vinegar Hill, a few miles from Paramatta, on the Hawkesbury road; a few were shot by the troops; the leaders were apprehended; three of them were led to instant death; two others were executed the following day at Sydney, three others at Castlehill, and the remainder returned quietly to their labour. There is no other instance of any insurrection in the colony by the convict population.

A printing-press had been established in the colony about the year 1795, by Governor Hunter, and in March 1803 the Sydney Gazette was published by authority. In 1800

---

Wales, New South.

a copper coin was issued by the government. The colony was at this time governed by general orders issued by the government. Captain King does not seem to have been adequate to the magnitude of the trust committed to him. He quitted the colony in August 1806, and was succeeded by Captain Bligh, who was even less qualified than his predecessor. He had given ominous proofs of his incapacity when he acted as commander of the Bounty, where by his tyrannical conduct he provoked the men to a mutiny; and his selection for the delicate task of rearing up this infant colony, by providing for its various interests, fostering the industrious, repressing the unruly, and discouraging and reclaiming the profligate, evinced a marked indifference to its welfare, which merits decided condemnation. His administration produced exactly the consequences which might have been expected. So unwarrantable was his tyranny, and especially his persecution of one influential person, noted alike for his public spirit and for his private virtues, that the colonists, with all the honest indignation of freemen, declared against his authority; and being aided by the officers and men of the New South Wales corps, they deposed him, and marching up to the government-house, they dragged him from his concealment behind a bed, and carefully protecting his person and property, sent him on board a sloop of war, in which he set sail for Europe, after he had been governor for eighteen months. He was succeeded by General Macquarrie, on the 1st January 1810; the government having in the mean time, from 1808 to December 1809, been successively administered by Lieutenant-colonels Johnston, Foveaux, and Colonel W. Patterson. During the government of General Macquarrie, which lasted for twelve years, the settlement made great progress in wealth and improvement. The population was increased by the influx of numerous convicts, and some new settlers; though it was not till a later period that the full tide of emigration began to set in towards New Holland. By aid from the British treasury, many public buildings were erected, roads were constructed, and the colonists, compelled by a season of drought in 1813, and animated by the spirit of discovery, made their way over the barrier of the Blue Mountains, hitherto deemed impassable. It was in search of new pasturage, and by following the course of the Grose river, that a pass was at last found, and a road commenced in the following year, over this mountain range, whose summits were considered by the aborigines to be inaccessible, and who often declared that there was no pass into the interior.[1] One great principle of Governor Macquarrie's administration was to encourage and bring forward the convict population. It was his maxim to consider the European life of every convict as past and forgotten; their arrival on the shores of Australasia as a new era in their existence, in which the errors of the past might be entirely redeemed. It was a most enlightened and benevolent policy; and if he erred in carrying it into effect with too little discretion, as was alleged, it was the error of a generous mind. Under his rule the convicts were patronised; some were chosen to be magistrates; he conferred on others colonial situations of trust, along with liberal grants of land. But his further endeavours to introduce into respectable society those who had been branded as felons, were opposed by the invincible antipathies of the European settlers, who, though they agreed in countenancing and rewarding good conduct in the convict population, could not be persuaded that any after-purity of life could thoroughly efface their original disgrace. To force them into the society of men of honour and character, was therefore a vain and useless attempt. Such an intermixture of classes could only be effected by the debasement of European manners, and by lowering the moral tone of society in the colony. Those who have been transported for felony can hardly ever aspire to the distinction that belongs only to moral worth. They may and ought to be treated kindly and indulgently; but a certain degree of disgrace attaches to their crimes, from which they cannot be freed; and it could hardly be expected that the new settlers would lay aside all at once their European prejudices in New Holland, and associate on familiar terms with men whose society they would have abhorred in Britain.

Sir Thomas Brisbane, a man of science and talent, succeeded General Macquarrie in 1821. His successor, General Darling, also possessed ability, but he was too jealous of the comments of the press, and involved himself in disputes and difficulties, some arising from his own indiscretion, others from the intemperate violence of his opponents. The present governor, General Bourke, has endeavoured to steer a middle course between these extremes, and has encountered opposition from both parties.

The British settlements in New South Wales were at first along Port Jackson and the Hawkesbury river. They have since extended backward into the country, and across the Blue Mountains, long deemed the barrier of the colony. They are divided into the following nineteen counties, namely, Cumberland, Camden, St Vincent, Northumberland, Gloucester, on the sea-coast; Durham, Hunter, Cook, Westmoreland, Argyle, Murray, farther into the interior; and still farther westward, Brisbane, Bligh, Philip, Wellington, Roxburgh, Bathurst, Georgiana, King. These nineteen comprise all the counties that have already been settled. They extend along the coast about 250 miles, and into the interior 180 miles. These nineteen counties, with the exception of Cumberland, Argyle, and Bathurst, have been but very imperfectly explored.

General aspect of the country.

On the sea-coast, along which the great Southern Ocean rolls its tremendous surge, the country is bold and rugged, and for five or six miles from the coast it wears in some parts a bleak and barren aspect; the soil is poor and swampy, and clothed with stinted trees. In other parts, however, the country on the coast, as at Illawarra in Camden, a maritime county to the north of Cumberland, has a different aspect; being, as described by Martin, romantic and beautiful, adorned with tall ferns, umbrageous cedars, graceful palm trees, with numerous creeping vines, throwing around in wild luxuriance their flowery tassels, here and there interspersed with flights of red-crested black cockatoos and purple couries, which present to the spectator the appearance of some tropical region, with the opposite property of a temperate climate. Beyond the girdle of the coast the country begins everywhere to improve, extending in gentle undulations for ten miles, clothed with stately forests, which, where cultivation has made progress, are diversified with farms and tenements, and intersected by broad and excellent turnpike roads. The forest is extremely thick, but there is little or no underwood. A poor kind of grass, which is too effectually sheltered from the rays of the sun to be possessed of any nutritive qualities, shoots up at intervals. This description of country, with few exceptions, forms another girdle of about ten miles in breadth, so that, generally speaking, the colony, for about sixteen miles into the interior, possesses a soil by no means fertile, but requiring both skill and industry to render it productive. At the distance however of twenty or twenty-five miles from the coast, the country begins greatly to improve.

To the northward, in about 28° south latitude, and seventy-seven miles from the settlement on Brisbane river, the country stretches out into vast plains, with rising downs, at an elevation of about 1800 feet above the level of the sea. They consist of a rich black and dry soil, timbered, and covered with the most luxuriant herbage, interspersed here and there with valleys, open woodlands, and forests. The height of the ground tempers the climate, which is genial and salubrious. Between the parallels of 34° and 27°, there is a vast area of depressed country, the course of the rivers being to north-north-west and north-west; which agrees with the opinion and the report of the natives, that there is a great lake in the interior, discharging its waters on the north-west coast. To the west and south-west of Sydney, the plains extend for 130 miles, destitute of trees, and not having a greater elevation of surface than 250 feet above the level of the sea. To the southward of the colony there are also vast plains, discovered in 1823, and called the Brisbane Downs. These fine pasture-lands extend upwards of forty miles south of the parallel of 36° 15′, which is their southern limit. They are enclosed on the east by the coast-range of hills, and on the west, towards the interior, by the lofty chain of the Australian Alps, known by the name of the Warragong chain, whose peaks are covered with snow all the year round. The table-land thus enclosed by mountains cannot be less than 2000 feet above the level of the sea; and possessing abundant pasturage, and a temperate climate, it affords an unlimited scope to the breed of fine-woolled sheep.[1]

---

[1] See History of Australasia, by R. Montgomery Martin, F. S. S.

To the westward of that portion of the country that has been settled or explored, various ranges of mountains are visible, down whose western declivities the streams descend, and afterwards taking a southerly course, fall into the ocean on the southern shore. The first discoveries of travellers in this direction were extremely imperfect. The Lachlan and the Macquarrie, both rising on the western side of the Blue Mountains, were, the first in 1817, and the latter in 1818, traced by Mr Oxley, the surveyor-general of the colony, to what he considered a swamp, spreading far and wide over a flat, where there was no outlet for the collected waters, and the whole country beyond he concluded to be an uninhabitable marsh. But in 1824, a journey westward was undertaken by Messrs Howell and Hume, which terminated in the discovery of several large rivers, the tributaries of another larger river, the Morrumbidgee, flowing in a direction nearly west. In 1830, Captain Sturt embarked on this river, which had been named after himself by Hume, and which he named the Murray, and descending the swelling stream, found that it joined the Murray river, which has its estuary by the shallow lake of Alexandrina in Encounter Bay, on the southern coast. In 1831 Major Mitchell, on the report of a bush-ranger, of a river which he had followed in a north-western direction from Liverpool Plains to the sea-coast, being sent by the governor on an expedition westward from that point, discovered a fresh-water river, the Karaula or Darling, in latitude 29°, flowing first westward and afterwards in a southern direction, and joining, along with the Morrumbidgee, the Murray river in Encounter Bay. As the structure of the country is gradually brought to light by these discoveries, we observe the broken fragments of its geography gradually pieced together, and at last united into one great whole. Mr Oxley traced the course of the Lachlan and Macquarrie westward a certain length. Other streams that take their rise north of the colony, namely, the Peel and the Namoy rivers, which flow down the western declivity of the coast-range, with a westerly or southerly course, were also traced a certain distance, and were then lost. The descent of the Morrumbidgee, and finally of the Murray, by Captain Sturt, was a valuable discovery, as it threw light on the interior structure of the country, and afforded data for geographical inferences of great importance; and, finally, the journey of Major Mitchell, in which he discovered the great stream of the Darling running almost southward, converted inference into fact, and would seem to point out the river Murray in Encounter Bay as the centre to which, from the nature of the ground, all the waters flow that rise in the great basin formed by the coast-range or the Blue Mountains on the east, and farther north by the Australian Alps, or Warragong range, and interior mountains not yet discovered, on the west; and that the Peel, the Namoy, the Macquarrie, the Lachlan, the Darling, with the Oxley, the Hume, the Goulburn, &c. which descend westward from the Warragong chain, whatever might be the direction of their upper streams, must finally terminate in the common embouchure at Encounter Bay.

This hypothesis, however, though it seems plausible, is not quite certain, and it is open in some points to objections. From the direction of the river Darling, which was discovered by Captain Sturt in 1829, and traced for forty miles through a level country to the south-west as far as 30° 16′ south latitude, 144° 50′ east longitude, it would seem to have no other outlet but in the Murray in Encounter Bay; and the fact of a large river falling into the Murray from the south, exactly the course the Darling would take in its progress to the sea, appears a further confirmation of this conjecture. Between the point however to which the Darling has been traced by Captain Sturt in its upper course, and that portion of the river which has been explored by the same traveller, there are 400 miles of unknown country. But the greatest objection is, that the Darling was found by Captain Sturt to be perfectly salt, especially as it was farther traced; while the river that he found to fall into the Murray was quite sweet to the taste. This fact seems sufficient to disprove the identity of the two rivers, though it seems certain that the Darling river must find its way to the southern shore; on which, however, though it has been carefully explored, no large river has been found, except where the Murray joins the sea at Encounter Bay.

The valley which is watered by these streams, is of great extent. Its declivities, according to the course of the streams, is to the south; and it is diversified throughout by ridges of mountains, diverging westward, some of them of great height. All this extensive country southward from the river Murray to the coast, Major Mitchell denominated, from its agreeable aspect and its fertility, Australia Felix. It is well watered; and the Snowy Mountains not only temper the climate, but they afford a supply of moisture throughout the summer to the large rivers to which they give birth; while the great Southern Ocean on three sides throws up clouds of moisture, which descend in abundant rains. Extensive downs occur, which are covered with the best kind of grass, or are gracefully wooded. From Mount Macedon Major Mitchell says he reconnoitred Port Philip at the distance of sixty miles. "In this region," he adds, "the party crossed ranges of granite, others of trap-rock, the woods forming open forests, which only partially covered the country. This, even in its present state, seems nearly all available for the purposes of agriculture and grazing; and being almost without any aboriginal inhabitants, it is consequently in the best state for the reception of British emigrants."[2]

The Blue Mountains, which run along the shore of New Holland at the distance of from thirty to ninety miles, and rise to a perpendicular elevation of from 3000 to 4000 feet, and farther south the Warragong range, or Australian Alps, which are covered with perpetual snow, and extend without interruption to Wilson's Promontory, the southern extremity of New Holland, form each, in the country which they occupy, the dividing ridge between the rivers which flow eastward to the ocean, and those which, with a westerly and afterwards a southerly course, and a larger and broader stream, terminate in the Southern Ocean, chiefly in the Murray river, at Encounter Bay. To the first class belongs the Hawkesbury, which is a continuation of the Nepean river, after the junction of the latter with a considerable stream called the Grose, and issues from a remarkable cleft in the Blue Mountains, in the vicinity of the town of Richmond, about forty miles from Sydney. It is apt to overflow its banks, from the sudden swelling of the mountain torrents by which it is fed; and in one instance rose near the town of Windsor, ninety-seven feet above its ordinary level. It falls into Broken Bay, fourteen miles to the north of Port Jackson, where it forms an excellent harbour. Hunter's river, about seventy miles to the north of Port Jackson, falls into the sea at the harbour of Newcastle. It is sufficiently safe and capacious for vessels of 300 tons burden, and navigable for small craft of thirty or forty tons burden for fifty miles above Newcastle. Manning river, still farther to the north, enters the sea by several mouths, in about latitude 31° 25′ south. Hastings river enters the sea at the large harbour of Port Macquarrie, 220 miles north-east of Port Jackson; it rises in south latitude 33½°, and 150° east longitude. Brisbane river falls into Moreton Bay, in latitude 27° 1′ south, longitude 153° 26′ east. It was discovered in 1823. Its source is in the mountain ranges to the north, and its course is through a large extent of fine country. Among the rivers that take their rise on the western ridge of the Blue Mountains is the Darling, which has its rise between the parallels of 27° and 33½°, and of which the course has been traced for about forty miles through a level country, and is supposed, as already stated, to be the same river which unites its waters with the Murray and Morrumbidgee, on the southern coast, though this is not certain. The Macquarrie river has likewise its origin in the torrents which descend the western ridges of the mountains. It has a winding course to the north-west, in some places deep, broad, and navigable for large boats, in others rapid, and obstructed by falls. It was seen by Mr Oxley to expand over the adjacent country, which had the appearance of a sea, but which was found in 1829, by Captain Sturt, after three years drought, to be converted into a vast expanse of arid soil. Its termination has not been distinctly traced, but it is supposed to be a tributary of the Darling. There are numerous streams which rise in the northern mountains, and which all terminate, as is most probable, in the main trunk, whether of the Darling or any other river which conveys the waters of this valley to their termination in Encounter Bay. The Lachlan river has its origin on the borders of Argyle county, between 34° and 35° of south latitude. Like the Macquarrie, it loses itself in a marsh, from which it emerges to join the Morrumbidgee in 34½° south latitude. The Morrumbidgee river has its origin in the Warragong range, 200 miles south-west of Sydney, in latitude 35° south, and about eighty miles from the eastern coast. It pursues a westerly course, and joins the Murray in latitude 34° 15′ south, and longitude 141° east, after pursuing a tortuous course of 800 or 1000 miles. The Murray is the central channel through which are conveyed to the ocean all the various streams which descend the western declivity of the great chain of mountains that runs along the coast. It has not been traced to its source, but it receives, as already stated, another river, supposed to be the Darling, and a second considerable stream which enters its left bank from the south-east. Mr Cunningham is of opinion that it is formed by the Hume and the Ovens streams, which take their rise in the Warragong Mountains, and flow west.

Soil and climate.

New Holland being situated in the southern hemisphere, its seasons are exactly the reverse of those in Britain. July is the middle of winter, and January of summer. The festivities of Christmas and of the new year are celebrated here, not, as in the old country, with doors and windows shut, and a cheerful fire to dispel the winter cold, but amid the oppression and heat of summer, with doors and windows thrown open to invite the refreshing breeze. We no longer hear in this Australian climate of the "gentle south wind," nor of "rude Boreas, blustering railer." The north is here the region of heat, as the south is of cold. Every thing is changed. Nature no longer wears a European dress, and poetry must conform and reverse its images. The summer extends from the 1st of December to the 1st of March. The mean heat during the three months of December, January, and February, is about 80° at noon. This great heat is tempered along the sea-coast by a regular sea-breeze, that sets in regularly about nine o'clock in the morning, and blows with considerable force till about six or seven o'clock in the evening, when it is succeeded by a land-breeze from the mountains, which varies from west-south-west to west. In very hot days the breeze often veers round to the north, and blows a gale. The hot winds to which the country is exposed, especially in the interior, three or four times every summer, blow from the north-west, like a current of air issuing from a heated furnace, raising the thermometer to 100° in the shade, and to 125° when exposed to their influence. They imbibe their heat from the tropical regions of the north, which they traverse, and which, like certain portions of Africa, are probably arid deserts. They are generally succeeded by a cold southerly squall, and by a thunder-storm and rain, which cools the air. The spring months are September, October, and November. In the beginning of September the nights are cold, but the days clear and pleasant. The thermometer varies from 60° to 70° towards the end of the month; and light showers occasionally prevail, with thunder and lightning. The days become gradually warmer, and in October the hot and blighting winds from the north begin to be apprehended. The three autumn months are March, April, and May. The first is rainy, and more fertile in floods than any other in the year. Towards the end of April the weather becomes perfectly clear and serene. The thermometer varies from 72° at noon to 60°, and in the mornings is as low as 52°. During May the thermometer varies from 50° at sunrise to 60° at noon, with a perfectly cloudless sky. During the three winter months of June, July, and August, the mornings and evenings are cold; hoar frosts are frequent, and become more severe in advancing into the interior. At Sydney the thermometer is rarely below 40°; at Paramatta it is frequently as low as 27° in the course of the winter. As the land rises from the ocean, the temperature declines. The winter at Bathurst, where snow falls in its season, is much colder than on the sea-shore. On the loftiest hills heavy falls of snow take place during the winter, and it remains for many days on their summits; and some high ranges penetrate the level of perpetual snow. In the valleys however the snow does not lie. The greatest defect in the climate is the prevalence of periodical droughts, during which the vegetation is parched for want of moisture, a general failure of the crops follows, and numbers of the cattle perish. Although in general a large quantity of rain falls throughout the year, yet the colony has hitherto been subject to severe drought every twelve years. A drought took place in 1826, which continued to 1829; and more recently, in 1839, another severe drought took place, which occasioned general distress in the colony. The climate is however on the whole highly salubrious and agreeable. Out of a community of 1200 persons, it has been known that only five or six have been sick at a time; and at some of the military stations, seven years have elapsed without the loss of a man.

Vegetable produce.

Wheat, maize, barley, oats, and rye are all grown in the colony of New Holland; but the two former are most cultivated. The heat at Sydney appears to be too great for the common species of barley and oats, though they are produced of a tolerable quality on the poorer soils. What is called the Siberian wheat arrives at very great perfection, and is greatly superior to the common species of barley; but being only used in the breweries, the demand is limited. The Indian corn, or maize, is of more general use, being much better adapted for the food of horses, oxen, pigs, and poultry. The produce is also much more abundant than that of barley and oats; and it has this additional recommendation to the settler, that it may be planted two months later than any other grain. The best months for sowing wheat are April, May, and June, though it may be sown from February to July, and even so late as August if that month happens to be moist. Oats and barley may be best sown in June, though they may be sown in the middle of August with a fair prospect of a crop. Indian corn may be planted from the end of September to the middle of December; but the best month is October. The wheat harvest generally commences partially about the middle of November, and is generally over by Christmas. The maize is not ripe till the end of March, and the gathering is not complete till the end of May. The culinary vegetables in Australia are numerous, and they thrive admirably in the climate. Potatoes, cabbages, carrots, parsnips, turnips, pease, beans, cauliflowers, lettuces, cucumbers, and in fact every species of vegetable known in this country, are produced in the colony. Many of them attain to greater perfection than in Europe, as the cauliflower and the brocoli, and the different varieties of the pea; and a few also degenerate, as the bean, for which the climate appears too hot, and the potato, which is not nearly of so good a quality as in this country. The colony is justly famed for the goodness and variety of its fruits. Peaches, apricots, nectarines, oranges, grapes, pears, plums, figs, pomegranates, raspberries, strawberries, and melons of all sorts, attain the highest degree of maturity in the open air; and even the pine-apple may be produced in a common hot-house. The climate at Sydney is not however so congenial to the fruits of the northern climate, as the apple, the pear, the currant, the gooseberry, and the cherry, which, though they are produced, do not equal in flavour those produced in this country. To the westward of the Blue Mountains, where the climate is colder, they attain to the same perfection as in Europe. Grapes of the finest quality are produced in New Holland; and some not wholly unsuccessful attempts have been made to manufacture wine, which might in time become a valuable export, and staple of commerce. Oranges, lemons, citrons, guavas, and other fruits, are so abundant that during part of the year swine are fed on peaches and apricots.

Animals.

The animal kingdom in New Holland is extremely curious and interesting. There are no large animals, such as elephants, lions, tigers, &c.; and there are few varieties. But the animals of New Holland are peculiar to the country, and are not found in any other quarter of the globe. The most remarkable animal found here is the kangaroo, of which there are very many varieties, from the kangaroo-rat to the forester, which stands from four to five feet high. The kangaroo, from its peculiar structure, the fore legs being so much shorter than those behind, does not run; but it advances by springs or bounds, the length of which is sometimes prodigious, exceeding twenty paces; at which rate they will proceed for some time, and outstrip the fleetest greyhounds. The abdominal pouch which this animal possesses, and into which, as in a burrow or nest, the mother shelters her helpless young, letting them out by day to graze on the tender herbage, or carefully conveying them across rivers and through forests when pursued by enemies, until they are able to provide for their own sustenance and safety, is extremely curious. The kangaroo is very timid, and it is only when it is hard pressed that it turns upon the hunters, when it will set its back against a tree, and boldly awaiting the dogs, will rip them up with its hard claws, or will give them such a hug with its fore-arms as to cause the blood to gush from the hounds' nostrils; and sometimes taking to the water, it will drown every dog that comes near it. These animals are fast disappearing before the progress of civilization; and it is a saying of the aborigines, "where white men sit down, kangaroo go away."[1] The opossum tribe are very numerous, and resemble those found in America. They take up their residence in the hollows of decayed trees, from which they are chased by the natives. The hyena opossum, or tiger, is very destructive among flocks. He sometimes measures six feet from the snout to the tail. He has a mouth like the wolf, with large jaws opening almost to the ears. The female carries its young in a pouch, like most of the other quadrupeds in the country. The native dog, which, next to the kangaroo and the opossum, is the animal most frequently met with, resembles the Indian jackal. It is about two and a half feet long, two feet high, with a head like a fox, and erect ears, and is of a reddish-brown colour. It preys on the sheep and poultry, making great havock among them; and is hunted without mercy by the settlers, who are fast extirpating the breed. The wombat is a kind of badger, weighing forty pounds; is good eating, and is in consequence quickly disappearing, as is also a species of sloth. The porcupine ant-eater is a small animal. A specimen mentioned by Mr Martin measured from the snout thirteen inches, the quills two inches long. It preys upon ant-eggs. There are varieties of the flying squirrel, fox, and mouse. The platypus is a singular animal, which it is difficult to know whether to class as a beast or as a bird. It has four legs like a quadruped, and a bill like a duck, and according to general belief lays eggs and suckles its young. It is about fourteen inches in length, and resembles an otter, though inferior in size; is covered with a very thick, soft, and beaver-like fur. It has a small flat head, and short legs terminating in a broad web. It has five claws; and in the male there is a perforated spur, through which is discharged a poisonous secretion. Of the domestic animals, there are those that are common in Britain, from which they have been imported. The breed of horses has been greatly improved, and is now excellent, insomuch that they are exported to India for the purpose of supplying the East India Company's cavalry and artillery. The horned cattle are in many instances of a gigantic size; and in this congenial climate and abundant pasture the sheep have an improved fleece, and are of a delicious flavour. Swine are abundant; goats are not numerous; and asses and mules are seldom reared, though a fine breed of the former has been introduced from South America. The camel would be a valuable addition to the domestic animals, as by his patience of thirst and fatigue he would be admirably fitted for long journeys in the interior of the country.

The ornithology of New South Wales is rich and various. The birds are numerous, and many of them of the most beautiful plumage. The emu, or cassowary, is one of the most remarkable of the feathered race, both for its great size, being six feet in height, and for its singular properties. Its covering is more like hair than feathers; it cannot fly, and being thus confined to the earth, has little of the character of birds. It is wonderfully fleet, outstripping the swiftest dog, and kicking with such violence as to break a man's leg. It is easily tamed, and becomes quite domestic. It is, like all the other wild creatures, fast disappearing before the progress of cultivation. The “gigantic crane,” or “native companion,” is a stately bird, about six feet high, of a pale ash colour, with a reddish tinge on the head. It is gregarious and carnivorous, and haunts the borders of rivers and lakes, where also the black swan is found. The bustard, or native turkey, is a large bird, weighing from fifteen to eighteen pounds, and is good eating. Eagles and hawks are to be found in all their varieties. Some are white and very large; the eagle-hawk measures nine feet from wing to wing, and is feathered to the toes. There are about thirty varieties of the pigeon; and the parrot species is in boundless variety, and of the most brilliant plumage. The cockatoos are easily domesticated, and taught to imitate sounds. Some of them are of milk-white; others black, richly variegated on the tail with red, and adorned with superb crests. The *lories*, green, red, crimson, and purple, are in great variety; and there are numerous birds not yet described by naturalists. The *spotted grosbeak* is of a light slate colour above, bill and tail deep crimson, throat black, and the sides are marked with snow-spots on the dark ground. The rifle-bird is nearly the size of a jay, its bill long and sickle-shaped, and colour a rich dark green, like velvet. The *ring oriole* is of a golden yellow and the deepest black, the feathers on the head resembling the softest velvet. The doves, in variety and beauty of plumage, surpass those in any other part of the world. The spur-winged plover is noted for a large spur upon the shoulder of each wing, with which it fights fiercely. There are two kinds of pheasants, and three of magpies. The common crow and the swallow are everywhere to be found; also the Australian sparrow, with varied plumage, in which a scarlet tinge is intermixed; the *butcher-bird*, or *laughing jackass*, which destroys snakes and other reptiles, so called from the resemblance of its note to a coarse and boisterous laugh; *the coach-whip*, a small bird, whose note resembles the crack of a short whip. Snipes, quails, king-fishers, and coots are abundant; also honey-suckers, woodpeckers, toucans, fly-catchers, warblers, cuckoos, and various species of small birds. Here are likewise to be found the pelican, penguin, goose, duck, teal, widgeon, frigate-bird, noddy, peterel, gull, and other sea-birds.[1]

---

[1] History of Australasia, by Montgomery Martin, chap. v.

Insects are numerous, and of every variety. Locusts are common in some parts of the colony. The butterflies are neither abundant nor beautiful. Of bees there are three kinds, all without stings. The flies are a great nuisance in summer, particularly one species, which taints and putrefies every thing it touches. The mosquitoes are disappearing with the progress of civilization. The spiders are very large; and caterpillars, at intervals of several years, swarm in incredible numbers, blighting in a few hours the finest fields of wheat. Measures have been taken to stop the ravages of this mischievous creature. Whence they come in such myriads, and almost in a single night, is unknown.

Reptiles are not at all in such numbers as they are in general in marshy countries. There are several varieties of the snake, some of them poisonous, namely, the *deaf adder*, which resembles the puff adder of America. It is thick, short, swelling out in the middle, with a flat head, and a cleft tail which opens and shuts like a forceps; its back is beautifully variegated with rows of red and white specks; and when irritated it seizes a stick as tenaciously as a cur dog. The diamond snake, which grows to the length of twelve or fifteen feet, is not poisonous. There is a small hazel-coloured snake, with two little flaps on its sides like fins; it darts along with great rapidity, and is termed the winged snake. Mr Martin saw a serpent at Paramatta, resembling the boa constrictor, fourteen feet long; its coat of a bright hue, but changing as the animal became irritated. Several water-snakes have been found, and at a considerable distance from the land. Scorpions, centipedes, tarantulas, and frogs are found. Lizards are numerous, but without the varied hues of those in the east. The guana is also found, of a dirty brown colour, and about four feet in length.

Fish are plentiful along the coasts; but they are not so plentiful in the rivers, especially in those in the eastern declivity of the Blue Mountains, owing to the rapidity of the currents. The fish called the *cod-fish*, though not the same as that known in Europe, is taken in the fresh-water rivers west of the Blue Mountains, in great quantities, of a large size, some weighing seventy pounds, and thirty pounds being very common. They are of a fine flavour; as are also the eels, which are caught of the weight of twelve or even twenty pounds. Perch, covered with scales and prickly fins, abound in the rivers on the eastern coast. In flavour and juiciness they resemble a sole. There are many varieties of other fish, with which the markets are well supplied; and of late sharks have been caught in Sydney Cove. Shell-fish are abundant. Fresh-water mussels have been found at Bathurst six inches long and three and a half broad, and shrimps are in great numbers. Oysters are found in great abundance around the Australian shores; every rock is covered with them; and though generally small, they are of a delicate flavour.

Minerals.

The country of New South Wales having been hitherto but imperfectly explored, its geology cannot be fully known. The line of coast, where the nature of the country has been chiefly ascertained, presents in its general aspect bold perpendicular cliffs of sandstone lying in horizontal strata, and interrupted occasionally by sandy beaches, behind which the country is low and flat. From the sea-coast to the river Nepean on the west, the sandstone seems to spread like a level platform; and although the country rises into hills and ridges, these seem to consist of a mass of clay, worn into inequalities on the surface by the action of the water, which accounts for the singular fact that the tops of the hills, which contain most of the original clay, are generally more fertile than the valleys, unless they contain alluvial deposits. Westward, or beyond Nepean river, the sandstone strata are forced upwards, and extend from north to south, forming the lofty ridge of the Blue Mountains. Towards the south the sandstone gives place in many parts to whinstone. On advancing farther to the south and west, granite and limestone are abundant, perforated in all directions with extensive subterraneous caverns, exactly resembling, in stalactitic decoration, those found in Europe and America. To the north-westward of Sydney occurs a fine limestone formation, which passes in some parts into a beautiful close-grained marble, affording materials to several skilful artisans in Sydney. In several other places other varieties of minerals are to be found. Hunter's river flows for a considerable distance over rocks of jasper, and beautiful agates, opal, and chalcedony; while innumerable petrifactions are found on its banks. Cornelian and agate have been found near the burning mountain of Wingen; some of the specimens crested with copper, and others presenting a beautiful auriferous appearance. For a more particular account of the mineralogy of New South Wales, the reader is referred to the work of Mr Montgomery Martin, which abounds in the most important information. We may add, however, respecting the coal formation, that this valuable mineral is found in several districts, especially in the country to the south of Hunter's river, about sixty miles north of Port Jackson, which is an extensive

---

[1] See History of Australasia, by Montgomery Martin, chap. iv.

Wales, New South.

coal-field. In this district is situated the town of Newcastle, so called from the produce in its neighbourhood. This district was originally the place of transportation for the most incorrigible class of offenders from Port Jackson, who are worked in chains from sunrise to sunset, in burning lime and in procuring coals and timber. In consequence of the fertility of the soil and the extent of water-communication, Hunter's river being navigable for 200 miles with boats, numerous emigrants reside in good farms along the shores of the river, and the country resembles the richest pastoral scenery in Devonshire.

Population.

An account of the aborigines of New South Wales will be found under the article AUSTRALASIA. That they will in the end gradually disappear, is no longer doubtful. In new settlements of the Europeans, they generally perish in the conflicts which take place between them and the intruders; but in New South Wales this enmity has subsided, and the most humane attempts have been made to reclaim them from their savage state. These efforts, however laudable, have been vain. Where the experiment has been tried under the most favourable circumstances, and they have been provided with every comfort, they have invariably relapsed into their primitive barbarity; so that in this respect New Holland will afford no exception to the general experience, that as the civilized inhabitants increase, the savage race invariably disappears. The British colony, when it was first established in Sydney, consisted of 1030 individuals, 700 of whom were convicts; and notwithstanding the discouragement of emigration by some of the authorities, the population, owing to the fineness of the climate and the number of convicts sent out, rapidly increased. A census has been taken at four different times, and the following is the result:

1810	8,293
1821	29,783
1828	36,598
1833	71,070

The following is a more particular account and classification of the inhabitants in the colony of New South Wales, according to a census taken on the 2d September 1836.

The total number of white inhabitants now in the colony is estimated at upwards of 100,000, of whom 25,000 are convicts, the residue of upwards of 90,000 who have been transported to the settlement since 1788. The population is divided into three classes: 1. the free settlers who have arrived in the colony, and their descendants; 2. those who have served their legal term, or who are free by pardon, the reward of good behaviour, and their descendants; and, 3. the convicts who are still in bondage. The convicts, when they arrive in New Holland, are conveyed, the male and the female prisoners, to different stations or barracks, which are surrounded by a high wall, and guarded by soldiers and several constables. The convicts are assigned as agricultural, manufacturing, or domestic labourers, to farmers and townspeople, who, in return for their services, are bound to provide them with food and clothing. Upwards of three fifths of all the prisoners in the colony are provided for in this manner. After serving a certain time with an unblemished character, the convict is entitled to a "ticket of leave," which makes him free within the district over which it extends; and if he does not forfeit this ticket by any crime for a certain number of years, he is then entitled to a conditional pardon, which makes him free within the precincts of the colony. And this system is found by experience to be attended with the most beneficial results. "On every side," says Montgomery Martin, in his account of this colony, "the traveller witnesses proofs of an industrious and prosperous community; he beholds ships, warehouses, steam-engines, farms, &c., the owners of which were transported from their natal soil, and who, after having paid the penalty demanded by the laws, have commenced a new life, setting an example of honesty, morality, and enterprise to those from whose abject condition they have emerged, and who are thus strongly urged to imitate their example." The second class consists of those who have been once prisoners, and are now free. They are termed *emancipists*, and by their industry are possessed of great wealth in land, houses, ships, and merchandise; and many of them are remarkable for probity, benevolence, and their enterprising spirit. The next and highest class consists of emigrants from Europe, either farmers, shopkeepers, merchants, or government officers and functionaries. Some individuals of this class refuse to associate in private with those who have been once convicted, though they be now free; and hence has arisen in the colony the distinction of the two opposite and hostile classes of *exclusionists* on the one hand, and *emancipists* on the other.

When the colony of New South Wales was first established, the whole powers of the government necessarily centered in the governor alone. In 1824, a council was appointed to aid and to control him in the exercise of his authority. Several alterations have since taken place, and the supreme authority is now vested, 1. in the governor; 2. in an executive council, which consists of the colonial secretary and treasurer, the bishop, and lieutenant-governor, which office has been recently abolished; and, 3. in a legislative council, consisting of the members of the executive council, with the addition of the chief justice, the attorney-general, the chief officer of the customs, the auditor-general, and seven individuals in the colony who are appointed by the crown for life. The legislative power is vested in the governor and in this legislative council, two thirds of which must concur before any law can be passed. The governor has the initiative of all laws, though any member of the council may request the governor to introduce a bill for the consideration of the council. If the governor decline, he must lay his reasons in writing, together with a copy of the bill, before the council; and any member disapproving of such refusal, may enter on the minutes the grounds of his disapprobation. Every bill passed by the council must be transmitted to the supreme court to be enrolled, when, if the judges represent that it is repugnant to the act 9 Geo. IV., or to the charter, or letters patent, or orders in council, or to the laws of England, it is again brought under the consideration of the council, and if again passed, proceeds into operation until the pleasure of her majesty be known. For the sole administration of the laws there is a supreme court, over which preside a chief and two puisne judges. The supreme court is a court of oyer and terminer, and gaol delivery; it is also a court of equity, and a court of admiralty for the trial of criminal offences within certain limits; it is empowered to grant letters of administration, and it is an insolvent debtors court. From the supreme court lies an appeal for all actions for less than L.500, to the governor or acting governor, who is directed to hold a court of appeals, from whose decision lies a final appeal to the king in council. There are courts of general and quarter sessions, which have the same powers as those in England. Courts of requests have been established for summarily determining claims not exceeding L.10; and their decision is final. Juries now sit in civil and criminal cases. A very vigilant police has been established throughout New South Wales. There are benches of stipendiary as well as unpaid magistrates in Sydney and other principal towns, aided by head-constables and a civil and military police-force at each station.

Internal intercourse.

The country of New South Wales, recently a pathless forest, is now intersected in all directions by excellent roads, some of them carried with equal labour and skill over lofty mountains, and bringing into close intercourse the remotest parts of the country by a daily increasing traffic. The royal mail proceeds from Sydney to all the different towns in the interior, and letters are delivered with punctuality and despatch. Stage-coaches with four horses also start from the same place daily, and from other places; so that there is every facility of internal intercourse by land; while numerous steam-vessels leave Sydney and ply along the coast to the different seaports.

Religion, education, &c.

There is here, as in the mother country, a variety of religious sects, a statement of whose respective numbers will be found in the population table already given. But different modes of faith here mingle in perfect harmony in all the duties of civil life. No religious distinctions are recognised; all classes, of whatever creed, enjoy equal rights, and are equally eligible to offices of honour or emolument; and the government provides equally for the maintenance of all sects. One seventh of the land was formerly appropriated to the support of the episcopal church: it is still applicable to the general purposes of religion and education, but without any distinction of sects, all of which participate equally in the government fund. Thus we find the principle of religious toleration more fully maintained in New South Wales than in the mother country, where there still exists a dominant religion fostered by the state. The episcopalian church was until very lately within the diocese of Calcutta. It is now subject to a bishop who resides in the country. There are, besides, fifteen chaplains of this church, who take charge of different districts in the country. There are four ministers of the established church of Scotland, and of the Roman Catholic clergy a vicar-general and six chaplains. The Wesleyan Missionary Society has four principal stations and upwards of sixty chapels, besides preaching stations, and five ordained missionaries, with several agents under them. There are also five Sunday schools, with 300 boys and 250 girls.

Great efforts have been made in Australia to promote education among all classes, and numerous excellent seminaries have been established. In the Australian College, instituted in 1831, are taught the ancient languages, English literature, and the sciences. This seminary consists of elementary schools, with a provision for the higher branches of education. Private establishments for education are numerous. Sydney College was instituted in 1830. It is under the control of a president and committee of management, consisting of emigrants and *emancipists;* those two classes joining amicably together in the promotion of knowledge. There are two excellent establishments, the male and female orphan schools, each containing 125 destitute children, who are reared from their infancy. There are several infant schools, thirty-three primary or parochial schools, in different parts of the colony; and two king's schools at Sydney and Paramatta, with classical teachers. There are a Mechanics School of Arts, an Australian Subscription Library, and various other societies connected with literature and science. The press, as usual, lends its aid to the diffusion of knowledge. It is not restrained by any law, nor by taxes of any description. The newspapers are numerous; some of them published every day, and others three times a week. In the town of Sydney there are six, and a New South Wales Magazine is published every month. The materials of these publications are chiefly supplied by local topics, though due attention is also given to the politics of Europe.

Finances.

The following is an abstract of the revenue of New South Wales, from 1826 to 1837.

HEAD OF REVENUE.	1826.	1827.	1828.	1829.	1830.	1831.	1832.	1833.	1834.	1835.	1836.	1837.

Miscellaneous.	1,661	1,018	762	968	776	2,172	786	688	876	3,549	*39,166	
Total	72,230	79,309	94,862	102,784	104,729	121,065	135,909	164,063	205,535	273,744	330,579	

* Water supplied to shipping from the dock yard, L.180 ; repayment of loans, including interest, L.292 ; ditto of advances to emigrants, L.96 ; the king's share of seizures by the customs, L.205 ; sale of property of convicted felons, chiefly stolen cattle, L.2459 ; surcharges recovered, L.127 ; miscellaneous, L.165 ; total, L.3549.

The revenue of the customs chiefly arises from a duty on the importation of spirits, of tobacco, and of manufactures ; of L.25 a year on licenses to distil spirituous liquors ; on auctioneers, L.2 per annum ; on butchers, carters, and carts ; on boatmen and boats ; on porters ; on dogs.

The following table contains the total expenditure in the colony for nine successive years, beginning with 1828. Expenditure in 1828, L.40,912 ; 1829, L.55,544 ; 1830, L.55,980 ; 1831, L.87,046 ; 1832, L.110,524 ; 1833, L.123,817 ; 1834, L.136,651 ; 1835, L.171,020 ; 1836, L.234,210. The revenue for 1837 amounted to L.460,217.

Commerce.

The trade of the colony has rapidly increased within the last few years, with the surplus produce of the country. The staple products of New South Wales are wool, whale-oil, cattle, and provisions. The first has become one of the most valuable articles of export, and now furnishes nearly one tenth of the foreign wool imported into this country. The origin and progress of this important branch of industry is remarkable. In 1810, only 167 lbs. of wool were imported into Britain from New South Wales and Van Diemen's Land ; in 1815, 73,171 lbs. ; in 1825, 323,995 lbs. ; in 1830, 1,967,309 lbs. ; and in 1836, 3,564,532 lbs.[1] The colony was indebted for the introduction of this article of wool to the enterprising spirit of Mr J. M'Arthur, who being convinced, so long ago as in 1793, that the climate and grasses of New South Wales would suit the Merino sheep, obtained a ram and two ewes from the Cape of Good Hope, which rapidly increased. Having afterwards explained his plans for the improvement of New South Wales to the privy council, he procured from the Merino flock of George III., two ewes and three rams, with which he returned to New South Wales, where these flocks are now increased to upwards of a million, of which the wool is highly prized in the London market, and has been sold as high as 10s. 4d. per lb. After wool, whale-oil is the chief staple of the colony. This article is also a recent product, which has been annually increasing. The number of ships employed in this trade in the year 1829, was 27 ; the value of the produce, L.94,101. In 1836, the number of ships amounted to 40 ; the value of the produce to L.126,085. The black whale is found in abundance along the coast of New South Wales. But the sperm fishing is the most valuable ; and in prosecution of this adventurous trade, forty vessels sailed out of Sydney in 1834. The value of the spermaceti and train oil exported in 1836 was L.141,532 ; namely, spermaceti, L.108,794 ; train oil, L.32,738.[2] The New Zealand flax (phormium tenax) is another article of export, which is yearly increasing in amount. In its appearance it is similar to English flax, and is chiefly dressed by the native women of New Zealand, who scrape off the outer part of the leaf with mussel-shells ; the inner fibres or filaments, resembling dressed flax, are then exported to Sydney, where it brings from L.15 to L.25 per ton. Timber, particularly cedar-plank, blue gum, and other timber, has been for some time exported. The value amounted in 1836 to L.14,385. Coals, which abound, and are worked in various parts, will prove a valuable staple of the colony ; and grain was exported in 1836 to the value of L.9306. The total value of the imports in 1836, according to accounts laid before parliament, was L.991,943 ; of the exports, L.599,893.

The shipping has increased along with the commerce, as will appear from the following account.

Vessels built and registered.

P or to 1817, the currency consisted principally of the priv e notes of merchants, traders, shopkeepers, publicans, and he amount was sometimes as low as sixpence. In this ear the Bank of New South Wales was established, with a ca tal of L.20,000, whose notes superseded this objectionable urrency. In 1825 the Bank of Australia was begun, with capital between L.300,000 and L.400,000, of which L.4 000 is paid up. The Bank of Australasia was establish in 1834, with a capital of L.200,000. There is also the ommercial Bank. All these banks have carried on a p sperous business, having paid a dividend from twelve to t enty per cent. The following is the amount of their resp tive circulation in 1836.

Bank of New South Wales	L.25,665
Bank of Australia	29,245
Commercial Bank	32,731
Bank of Australasia	11,846
	L.99,487

T e whole amount of British coin in the colony is estimat to amount to L.445,000.[1]

F m the preceding account of this prosperous and interest g colony, it will be seen that it has taken root in the cou ry, and that it will progressively and rapidly increase, unti he whole island be overspread with a civilized populatio At the same time, those who have explored the interi of New South Wales do not bring back a good report of t land. The general testimony is, that the good land is ch fly confined to the banks of rivers; and, with the excep n of these, it bears a small proportion to the poor and barr tracts. Many parts are but indifferently watered, and general water is not abundant; and during the long drou hts to which the country is liable, great distress must freq ntly ensue from this cause. To contend with these disa antages, which will be the lot of succeeding generation will require the full exercise of European skill and indu ry; and still the country, from its nature, will never supp rt a dense population.

A in all new colonies, there is a scarcity both of labour and pital, and consequently a high rate of wages and profits which, however inconvenient in some respects, must ope e nevertheless as a powerful stimulus to internal impro ment. The hire of mechanics is from six to eight shil gs per day, and of common labour in proportion. The olony thus presents a decided contrast to the mother cou y, where the market is overstocked, where the great diffi lty is to find employment for labour, and where, from he low rate of wages, the labourer can scarcely maintain imself and his family. The want of labour in New Sou Wales could be speedily supplied from the overcrow ed community of this country, to the great benefit of both but the expense of the voyage entirely prevents the emi ation of the poorer class. In this case, there cannot be wiser policy than to assist them with the necessary funds, and to this purpose rigidly to apply the sums that are received by government for the sale of lands in the colony. This system has been so far adopted; but the colonists complain that the emigration fund, as it is termed, which amounts to between L.100,000 and L.200,000 annually,[2] is diverted from this paramount object, to others less important. So essential is an adequate supply of labour to the improvement of the colony, that the whole sum received for the sale of lands, they insist, should be laid out in facilitating emigration. The time however is fast approaching when the internal administration of this country must be committed to a legislative assembly of its own inhabitants. They are the best judges of their own affairs, and have the deepest interest in the public welfare; and it is only by a free constitution that abuses can be corrected, and that the colony can possess any security for the upright and careful management of its concerns.

Of late years, British colonies have been established on the western coast of New South Wales, at Swan river, and on the southern shore, on the Gulf of St Vincent, at Port Adelaide; and farther west, a new settlement has been begun at Port Philip, opposite to Van Diemen's Land. It was in 1829 that a number of settlers left England for Swan river, and located themselves on the banks of the Swan and Canning; and by the end of the year, the new residents amounted to 850, and the non-residents to 440. The settlers received grants of land in proportion to the capital which they had to invest; and Mr Peel received 500,000 acres on condition of conveying a certain number of emigrants to the colony. Many difficulties and hardships were at first experienced. The land near the coast was found poor and sandy; but in the interior, fine pastoral and agricultural tracts have been discovered. Thus Western Australia seems to be of the same character as the eastern coast. A border of inferior land, diversified with rich tracts near the principal rivers, is bounded on the east by a range of primitive mountains, rising between 3000 and 4000 feet above the level of the sea, and occasionally showing the bare granite. Beyond these appears a level country, superior to the coast district, without however being anywhere highly productive, but covered with excellent pasture, where stock, and especially sheep, thrive well. The colony which has been established on this western coast, having overcome the first difficulties, now begins to prosper and to increase. Several townships have been established, namely, Freemantle, Perth, and Guildford, on the Swan river, and Augusta at the mouth of the Blackwood. There are several hotels, with excellent accommodations, and the state of society is well spoken of. Sir James Stirling was the founder, and is the governor. The coast abounds in excellent harbours, several of which are much frequented by sealing vessels. The temperature is warm and dry, and the climate salubrious. The governor has an executive and a legislative council to assist and to advise him, and there are about thirty magistrates in the colony. Several thousand sheep and fine cattle are depastured in different parts. Roads have been formed, and public buildings erected; and a newspaper, first published in manuscript, now issues every week from the press, which is in full operation on the banks of the Swan river. Wool of a superior quality, plaster of Paris, and timber, have been exported to England.

The coast of South Australia, deeply indented with various inlets and commodious harbours, presents several advantageous situations for a settlement; and accordingly a charter was granted in 1834, to a colony to be established between east longitude 132° and 141°, and 26° of south latitude from the Southern Ocean. An adventurous band of emigrants accordingly proceeded to take possession of the country along the shore of St Vincent's Gulf, where they founded a settlement and town, which they called Port Adelaide. They encountered the usual difficulties of new settlers, but the colony now prospers and increases. The inhabitants in 1839 amounted to between 8000 and 9000. In 1837, the land sales, at the rate of twenty shillings per acre, produced L.3300, in 1838 L.37,800, and in 1839 it was estimated that they would amount to between L.50,000 and L.60,000. Between February 1837 and September 1838, twenty-eight vessels arrived, with between 500 and 600 emigrants. The greatest care was taken to obtain a moral and industrious population. Schools are already established, every effort has been made to conciliate the natives, several of their tribes being settled within the colony, and located in fixed habitations, where there is a school, with an interpreter, who is endeavouring to train them to civilized habits.[1] On the 30th June 1840, the population of South Australia amounted to 14,000. In Adelaide there were eight churches and meeting-houses, houses built of brick or stone 816, of wood 1588. The wages for carpenters were from 12s. to 15s. per day, masons and bricklayers 12s. to 14s., labourers 6s. to 7s.; men servants L.25 to L.60 per annum, women servants L.12 to L.25. Of the live stock there were, sheep 180,000, bringing prices from 25s. to 40s.; cattle 15,000, L.12 to L.20; horses 1500, L.30 to L.150; pigs 3600, L.2 to L.6; goats 400, L.3 to L.6. Of the land selected, there were 1042 acres in the town of Adelaide, 1053 in the port of Adelaide; of rural lands there were 357,880 acres; total number of acres surveyed, 359,975; special surveys of 4000 acres each, 36. The number of ships which arrived in the colony was 104, tonnage 19,399; number of ships from Europe 18, now in the harbour 12, tonnage 3059.

[1] See Tables of the Revenue, &c. of the United Kingdom and its Dependencies, p. 85.

[2] It amounted in 1837 to L.120,427. See Account ordered by the House of Commons, 27th August 1839.

A settlement has more recently been formed at Port Philip, on the southern shore of New Holland, between 144° and 146° east longitude, to which settlers are resorting in great numbers; and the original locations have already greatly advanced in value. The comparative vicinity of this settlement to Sydney, with which there is a land communication, and to Van Diemen's Land, must give it a preference to Swan River settlement, with which the communication is by a long sea-voyage. Nor can the settlement at Port Adelaide communicate so conveniently with the parent colony. The sea-coast is also indented with deep and extensive inlets, which would afford accommodation, equally capacious and safe, for any number or size of shipping. These natural harbours are on so grand a scale, that the most magnificent works of art appear insignificant in the comparison. (F.)

WALKJ, a circle of the Russian government of Ukraine, extending in north latitude from 49° 33′ to 50° 2′, and in east longitude from 35° 9′ to 35° 48′. It comprehends 660 square miles, with one city, eighty-three towns, many scattered farms and houses, and 65,700 inhabitants. The chief employments are agriculture, breeding cattle, and distillation. The capital is a city of the same name on the river Moscha. It contains 1450 houses, five churches, and 9820 inhabitants, who subsist by trading in the produce of the soil. It is 1003 miles from St Petersburg. Long. 35. 50. E. Lat. 49. 50. N.

WALLACE, Sir William, the name of one well known to the readers of British history, as the heroic defender of Scotish independence against the aggressions of Edward I. of England. He was the second of three sons of Sir Malcolm Wallace (or Walays) of Elderslie and Auchinbothie, in the county of Renfrew, and not far from the town of Paisley. The earlier years of Wallace appear to have been spent at Dunipace, in Stirlingshire, in the society of his uncle, a wealthy priest, who gave him an education far above what was usual in those times, and whose strong love of liberty fostered his nephew's youthful enmity against the English. The early rudiments of education thus acquired were afterwards strengthened by the instruction which he received at Dundee. At this period of life he also acquired those hardy and warlike accomplishments, which inured his frame to fatigue, and gave him a ready command of the weapons of war. His early hatred of the English led him into many brawls and adventures;[2] but it was not till after the battle of Dunbar, when Scotland was completely overrun, that he first came prominently before his countrymen. In 1297, in a skirmish, in which several were killed, he slew with his dagger William de Hesilridge, the sheriff of Clydesdale. For this deed he was proclaimed a traitor, outlawed, and driven from home to the wilds and fastnesses of the country, where he joined himself to men whose fortunes were as desperate as his own, and his courage and higher rank made them choose him for their chief. From this time he was constantly engaged against the enemy with various results, but ultimately, as his adherents increased, and his plans became more matured, with decided advantage. This kind of guerilla warfare was of the utmost importance in his future proceedings. By it he became acquainted with the strongest passes and the best positions for defence in the country; his men were inured to a life of fatigue and privation, to feel the benefits of discipline and obedience, and to rest with the most perfect confidence in the abilities, courage, and great strength of their intrepid commander.

The success which attended his efforts induced him to undertake an enterprise of greater importance. By a forced march he surprised Ormesby, the English justiciary, at Scone, defeated his troops, nearly captured him, and took a rich booty. This exploit led Bruce and a number of the nobility to join him with their vassals; and the united forces, led by Wallace, cleared the country of the English. This intelligence reached Edward when about to embark for Flanders. An army of 40,000 foot and 300 horse was despatched into Scotland, under the command of Henry Percy, which on the 9th of July 1297 came up with that of the Scots, encamped at Irvine, consisting of nearly the same strength, and commanded by Wallace. Dissensions had however broken out among the leaders: the feudal barons, from pride and jealousy, would not submit to his orders, and they therefore entered into negociations with Percy, which ended in their submission to Edward. Sir Andrew Murray of Bothwell was the only man of rank who adhered to Wallace; and with a large body of tried and veteran followers, they retired indignantly to the north. Percy, considering that he had put an end to the revolt, retired to England; but Wallace and Murray, dividing their forces, carried on their operations against the English, and with such vigour, that in a short time all the strongholds north of the river Forth, except the castle of Dundee, were retaken. Wallace had just laid siege to that fortress, when his scouts informed him of the approach of a powerful force, under the command of the earl of Surrey, and Cressingham the treasurer. He instantly left the siege, to be continued by the citizens, and by a forced march took possession of the high ground on the river Forth, above Cambuskenneth, at Stirling, before the English forces reached the south side of the river. The Scotish army, consisted of 40,000 foot and 180 horse, while that of the English amounted to 50,000 foot and 1000 heavy armed horse. On the morning of September 11, 1297, against the advice of those who knew the nature of the ground, Surrey ordered his troops to deploy over the narrow bridge; but when only half their number had passed, and before their ranks could be arrayed on the narrow peninsula which formed the field of battle, Wallace attacked them with his whole force, and nearly every soldier that crossed the bridge was either slain or drowned. This decisive defeat was followed by the expulsion of the English from the kingdom. To lessen the severity of a dreadful dearth and famine which now spread over Scotland, Wallace resolved on an expedition into England, not only to procure subsistence for his numerous army, but also to retaliate on that country the injuries which Scotland had received. He therefore proceeded as far as Newcastle, wasting the northern counties with fire and sword, sparing neither age nor sex, and carrying off a large and valuable booty. Soon after his return from this successful expedition, he was elected governor of Scotland, and, strengthened by this high title, he proceeded to regulate the affairs of the kingdom, which its exigencies required. So firm and determined was his rule, so beneficial his measures, that the powerful nobility were compelled to submit to his authority, while the lesser barons willingly supported him. This state did not long continue. Edward, in July 1298, at the head of an army of nearly 100,000 foot and 8000 horsemen, entered Scotland, while Wallace retired before him as he advanced, wasting the country, so as to make Edward depend on his own supplies. This plan of warfare reduced the English army to such straits that the king had to order an inglorious retreat. At this critical moment, when the military skill of Wallace predicted the most complete success, the treachery of two Scotish nobles, Patrick earl of Dunbar, and the earl of Angus, revealed to the English monarch the dispositions of Wallace. Edward immediately ordered his army to advance, and by a rapid night-march, came up to the Scottish army at Falkirk; and Wallace, with not one third the number of soldiers, was compelled by his position to fight at disadvantage, and was defeated with great loss. Shortly after this defeat, he resigned his high office as governor, and proceeded to France, apparently with the consent of the regents, with the expectation of obtaining assistance for Scotland from its sovereign. In this he was deceived, as, on arriving at Amiens, he was thrown into prison, and a letter was written by Philip to Edward, offering to send him to London. In this however there was more policy than sincerity; for Wallace was secretly released from prison, and furnished with letters, dated November 3, 1298, to the French agents at the court of Rome, ordering them to solicit Pope Boniface to give Wallace an attentive hearing regarding the affairs of Scotland. There is no proof that Wallace went to Rome, but certain it is that Boniface, in his bull to Edward, exhibited a knowledge of its history and affairs which he could only have derived from such a source as Wallace. This noble-minded patriot remained on the continent until late in the year 1303, when he returned into Scotland, and immediately commenced active operations in assisting those who still defended the liberties of their country. By his resolute career, he rendered himself so obnoxious to Edward, that when mercy was extended to the few remaining patriots on certain conditions, Edward excluded this great man, and set a reward of 300 merks on his head. By the treachery of a servant who waited on him, of the name of Jack Short, he was at length betrayed to Sir John Monteith, a Scottish baron, who captured him at night in bed in the house of a certain Ralph Rae, at Robroyston, in the neighbourhood of Glasgow, and for which he received from the English privy council a grant of land of the annual value of one hundred pounds. Wallace was conveyed to London, where he arrived upon Sunday the 22d of August 1305. On the following day he was tried in Westminster Hall, with mock splendour and ceremony, by the form of English law, but without the least regard to its justice. In accordance with the predetermined resolution of Edward, he was condemned to suffer death, and the sentence was executed the same day, with disgraceful and revolting cruelty.

[2] See Henry's Wallace, by Dr Jamieson; and Carrick's Life of Wallace.

Thus ended the career of this noble-minded patriot, but not without leaving a name which will ever be revered. He found his country overpowered and disorganized, her people disheartened, her nobles and leaders in prison, or in the pay of one of the ablest monarchs that ever swayed the English sceptre, himself without wealth or influence, and an outlaw; yet under all these disadvantages, his love of freedom and hatred of oppression, his fearless courage and perseverance, which nothing could subdue, his military skill, his political sagacity, his natural eloquence, and the ardour with which he animated his companions and followers, all conspired to restore confidence in his countrymen, and to free them from the invaders; and had it not been for the pride, jealousy, and treachery of her nobles, the measures that he pursued for organizing the strength and extending the commerce of the kingdom would have given it a stability, which the warlike power of the English, aided by the experience, military tactics, and judgment of her monarch, would not have been able to overpower. As it was, both he and his country suffered from the venality of those who by birth and power were her natural protectors.

His person was of the most perfect form, and of a stature approaching the gigantic. In strength he was superior to the strongest men of his day; and his frame was such, that it was capable of bearing the greatest fatigue. At his execution it is probable that he was not above thirty-five years of age.

WALLER, Edmund, a conspicuous improver of English versification, was born at Coleshill in Hertfordshire, on the third of March 1605. He was the son of Robert Waller of Agmondesham in Buckinghamshire, and the nephew of John Hampden, whose name has been transmitted to posterity by means very different from those employed by his kinsman. Waller's mother was the cousin of Oliver Cromwell; and he could trace his pedigree from Richard Waller of Spendhurst, the sheriff of Kent, who took the duke of Orleans prisoner at the battle of Agincourt. While he was yet an infant, his father died, leaving him three thousand five hundred pounds a year, which in those days was a splendid fortune. He was sent by his mother first to Eton, and then to King's College, Cambridge; but we find him converted into a senator, and frequenting the court of James the First, in the sixteenth, or, as others say, the eighteenth year of his age.

About the same period of life he is supposed to have written his first poem, "On the danger his Majesty (being prince) escaped in the road at St Andero." The prince landed at Portsmouth in 1623, when Waller was in his eighteenth year; but, whenever the poem was begun, it could not have been finished until two years afterwards; for he predicts the marriage of Charles with Henrietta of France, and it belonged to the bards of a more remote age to prophecy any events but such as had already happened, or never afterwards occurred. The numbers of this production are as musical as those of his last; and if the sense had always been completed in every couplet, few rhymes of the present day could better satisfy the public ear. "We have our lineal descendants and clans," says Dryden, in the preface to his Fables, "as well as other families: Spenser more than once insinuates that the soul of Chaucer was transfused into his body, and that he was begotten by him two hundred years after his decease. Milton has acknowledged to me that Spenser was his original; and many besides myself have heard our famous Waller own that he derived the harmony of his numbers from the Godfrey of Bulloign, which was turned into English by Mr Fairfax." Waller's second poem was written on the occasion "Of his Majesty receiving the Duke of Buckingham's Death." The duke was assassinated by Felton in 1628, and "the steadiness," as Johnson observes, "with which the king received the news in the chapel deserved indeed to be rescued from oblivion." There are few persons, however, who have not had frequent occasion to admire the philosophic composure with which some of their friends can listen to the calamities of others. There is sufficient internal evidence to demonstrate that this poem has no better pretensions than its predecessor to be considered a hasty effusion of fancy. He was indeed incapable of producing any thing on the spur of the occasion. The duke of Buckinghamshire told Fenton, that he spent the greater part of a summer in composing and correcting ten lines to be written in a copy of Tasso belonging to the duchess of York.

Waller now pursued an earthly mistress, who suffered herself to be more speedily overtaken than the Muse. When still very young, he obtained the hand of Miss Banks, a rich city heiress, in opposition to the addresses of Mr Crofts, whose suit was backed by the influence of the court. By this lady he had two children, a son, who died in infancy, and a daughter, who afterwards became the wife of one Mr Dormer of Oxfordshire. When Waller was about twenty-five years of age, his wife died in giving birth to a child, whether the one last mentioned does not appear. A rich young widower is more easily reconciled to the loss which he has sustained, than one who is left in solitary indigence to pine away the evening of his days. Looking about for another wife, or perhaps only for a poetical mistress, Waller fixed his eyes on the Lady Dorothea Sidney, the eldest daughter of the earl of Leicester. He began to celebrate this lady in verse under the absurd name of Sacharissa; but his tuneful gallantry is said to have been rewarded with contempt, for which he took a severe though late revenge. Meeting accidentally with Waller after she had become a wrinkled widow, she asked him, with senseless and indelicate jocularity, when he proposed to write some more verses to her? "When you are as young, madam," he answered, "and as handsome as you were." After this disappointment, Apollo laid the following injunction on the slighted bard:

On yon aged tree
Hang up thy lute, and hie thee to the sea.

Fenton supposes it possible that he may have diverted his chagrin by accompanying the earl of Warwick to the Bermudas; and the knowledge of whale-fishing as practised by the inhabitants of that archipelago, displayed in his Battle of the Summer Islands, lends some strength to this conjecture. This poem, whether a record of experience, or an effort of imagination, is so unhappy both in the design and execution, that it is difficult to determine whether the poet is in jest or earnest. From 1629 to 1640 no parliament was assembled, and Waller spent a great part of that interval in prosecuting his studies, which were directed by Mr Morley, afterwards bishop of Winchester. He continued to produce various pieces; but to ascertain the precise order in which they were written, is of as little interest or utility as to be informed which was the third, fourth, or fifth bullet that was cast in some particular mould. In other poets it is curious to watch the progress of excellence; but Waller's powers arrived at sudden maturity, and remained unimpaired to the last; his first poetical essays exhibit none of the tasteless crudities of youth, and it is not easy to believe that his latest efforts were the children of decrepitude.

Having forgotten the cruelty of Sacharissa, he married a lady of such inferior celebrity that it is not known whether her name was Bresse or Breaux. It is however certain that she made him the father of thirteen children, five sons and eight daughters. In the parliament of 1640 he stood up in his place and opposed the king's demand of a supply. In his speech, which still remains, Johnson remarks that he quotes Hooker in one passage, and copies him in another, without acknowledgment; a proceeding resembling that of one who should borrow a sum of money from a man, and afterwards pick his pocket. Notwithstanding the vehemence of this harangue, the king is said to have sent to him to second his demand of some subsidies for the payment of the troops. Waller was not sufficiently flattered by this distinction to decline undertaking the prosecution of Sir Francis Crawley, one of the twelve judges who had declared that ship-money might be legally and equitably exacted from the subject. This was an employment worthy the nephew of Hampden, and he executed his task with great dignity and vigour. The most brilliant passage of a very eloquent speech, which he delivered upon that occasion, is the one in which he compares the atrocious villany of enslaving and beggaring the nation, under pretence of supplying the navy, to the barbarity of seething a kid in his mother's milk; an act of inhumanity which the Mosaic law forbids, and which is understood to mean the employing for the destruction of any creature what was intended for its preservation. Crawley escaped unpunished; but Waller's speech was so much admired that twenty thousand copies were sold in one day. Though a friend of reform, both civil and ecclesiastical, Waller was no enemy either to the church or the king; for he spoke in favour of episcopacy, and when Charles took up arms against his subjects, he sent him a thousand broad pieces. But in times like those, the loyalty or patriotism of timid contemplation could be of small service either to a tyrant or a mob; and it was of little consequence whether a faltering voice muttered prerogative or privilege.

We have seen Waller perform the part of a public accuser; he has now to appear in the character of an abject criminal. In an evil hour he turned plotter against the parliament. Being one of the commissioners appointed to treat with Charles at Oxford after the battle of Edgehill, the king said some kind things to him, which are supposed to have melted his heart, and given rise to the abortive scheme called Waller's Plot; or perhaps his loyalty, wavering as it was, was transmitted to him by his mother, who, although the sister of Hampden, was so zealous a royalist, that her kinsman Cromwell, half jesting and half serious, made her a prisoner to her own daughter in her own house. This plot of Waller's, which, as Hume says, might with more propriety be called a project, was a secret association of persons disgusted with the violence of the commons, to communicate with those of their own principles, who, when their strength was united, might, as they hoped, be enabled to make a stand against the progress of treason, by petitioning for peace, and refusing to contribute to the support of the parliamentary forces. The probability of success in this undertaking Waller was in the habit of discussing with his brother-in-law Tomkyns, who was clerk of the queen's council. Lord Conway, who had served in the army, was one of their confederates, and, as Clarendon supposes, might possibly have harboured some ulterior design of an appeal to the sword; but, as far as Waller was concerned, the scheme was of a nature purely civil, and such as might have been attempted with perfect safety at any other period. Infant anarchy however is still more jealous and malignant than superannuated despotism. About the same time that Waller's plans were discovered, there came to light an enterprise of a more martial aspect, projected by Sir Nicholas Crispe, who had obtained from the king a commission of array, transmitted to London by Lady Aubigney. Of these two unconnected schemes it was not difficult to make one direful confederacy.

Of the discovery of Waller's plot two distinct accounts are given. Clarendon relates that a conference between Waller and Tomkyns was overheard by a servant of the former, who carried the information thus obtained to Pym. One of Waller's relations, who lived in his family, left behind him a manuscript, in which it is stated that "he was betrayed by his sister Price,[1] and her presbyterian chaplain Mr Good, who stole some of his papers; and if he had not strangely dreamed, the night before he was seized, that his sister had betrayed him, and therefore burnt the rest of his papers by the fire left in his chimney, he had certainly lost his life for it." Whether discovered by the unnatural perfidy of a sister, or the ordinary rascality of a domestic, the plot was published, with every embellishment that could excite surprise and terror. On Wednesday the 31st of May 16, when a solemn fast was held in St Margaret's church, Westminster, a breathless messenger rushed among the congregation, and delivered a letter to Pym, who read it, looked aghast, whispered to some of the members of the congregation, and left the church, accompanied by those to whom the awful secret was divulged. On the night of that day Waller and Tomkyns were apprehended. Nature had withheld from these associates one quality, without which a detected conspirator cuts a figure truly despicable. Perhaps the old adage, that the greatest rogue is the first to turn king's evidence, is susceptible of some amendment. Experience has proved that in desperate coalitions the blood of his comrades is more frequently sold by the greatest coward, than by the greatest villain of the gang. In the hope of meriting a pardon, Tomkyns was willing to sacrifice the life of Sir Nicholas Crispe, that famous London merchant, who raised a hundred thousand pounds for the king at his utmost need, and fought at the head of a regiment which his own indefatigable loyalty had embodied. The commission of array Tomkyns had been sent with the appointed token to receive from Lady Aubigney, who knew nothing of the nature of the document with which she had been intrusted. He had buried it in his garden, where, in consequence of his information, it was found, and thus was the daring enterprise of Crispe identified with the tame cabal of Waller. As for him, he was seized with the most acute paroxysms of terror, under the influence of which he blabbed out all, and perhaps more than he knew. No malapert urchin in a dark room, the chosen residence of ghosts and goblins, ever petitioned with more frantic importunity for enlargement. He confessed not only his own delinquencies in thought, word, and deed, but all that he had seen, heard, or suspected of others; he divulged even the confidential prattle of women; and, for the privilege of passing the remainder of his days in penury and shame, would doubtless have consigned the whole of his associates to perdition. Lord Conway and the earl of Portland were his confederates in this disastrous scheme; and, to complete the sum of his degradation, he wrote a letter to the earl, imploring him, with all the eloquence of fear, to secure their mutual safety by becoming as mean a traitor as himself. To the honour of the peerage, his lordship treated this proposal with contempt. Being unable to find a partner in ignominy, Waller now endeavoured to excite compassion and gain time by counterfeiting madness, as Clarendon says, or, according to May the historian of the parliament, the deepest remorse of conscience. To the ghostly counsel of the ministers he listened with every appearance of edification, and rewarded their spiritual services with profuse liberality. No corruptible person who had the smallest influence on his fate went without a bribe. These desperate struggles were at length successful. In the pitiful palinode which he spoke before his expulsion from the house, among many other moving things, he said, "I am of a stock which hath born you better fruit." But this touching appeal made little impression on his hearers, and he owed his deliverance, not to his eloquence, but to his purse. Nor could he reasonably expect much favour at the hands of the commons. He had remained in parliament against his own inclination, by the express command of the king, and was in the habitual practice of exasperating the members by venting the most distasteful sentiments. Clarendon and Whitlocke are at issue on the mode of his deliverance; the former stating that he was tried by the parliament, according to the earnest prayer of a speech contained in his works, and the other that he was delivered over to the council of war, by which he was condemned to death, but reprieved by Essex, the leader of the parliamentary forces, and was suffered, after one year's imprisonment, to depart into another country, upon paying a fine of ten thousand pounds. However his release was effected, it cost him the whole of his honour, and more than a moiety of his estate.

Waller now proceeded to France; and, judging that the best way to stop the mouth of ridicule was to fill it full of dainties, he kept open house, and gave sumptuous entertainments. His favourite daughter Margaret, who afterwards acted as his amanuensis, was born at Rouen in Normandy. Soon after his exile commenced, he received a letter from an English lady, whose name has not been discovered, desiring him to collect his poems and send them to her from France. With this request he complied, and they were published in London in 1648. The splendid ostentation in which he lived terminated in humiliating embarrassments, to which he had been very little accustomed. He was compelled to part with his wife's jewels; and having nothing left, as he said, but the rump-jewel, he desired his brother-in-law, Colonel Scroope, to solicit permission from Cromwell to return. This boon was granted; and when he arrived in England, he went to live upon the remains of his fortune at Hallbarn, a place near Beaconsfield, where his mother resided. The protector recognised him as a relation, and, according to Waller's own account, used to lay aside the mask of hypocrisy in his society. His condescension was not thrown away, for Waller testified his gratitude by producing in 1654 the celebrated "Panegyric to the Lord Protector," which has always been considered his masterpiece.[2] The panegyric was followed by a poem on the war with Spain, in which he advises the nation to decorate the head of Cromwell with a crown made of Spanish gold. When that crafty head was laid low, Waller was ready with an epicedium. Cromwell could now neither benefit nor injure him; but the verses were probably produced before his son Richard withdrew into that obscurity which was his natural element. If this poem is a labour of love, it is valuable on that account alone; it is very short, begins with common-place, and ends with hyperbole. Nature is always supposed by poets to be convulsed when great spirits pass away, and it happened to be rough weather when Oliver died, a circumstance of which Waller has taken a very feeble advantage; but that the goddess should heave one tremendous sigh, that should despatch the waves as messengers of woe to distant climes, is the conception of frigid extravagance. When Charles appeared, Waller's song of triumph was not withheld. The verses "to the King upon his Majesty's happy Return," Charles told Waller that he thought inferior to the panegyric upon Cromwell. "Poets, Sir," replied he, "succeed better in fiction than in truth." During the whole of this reign, Waller represented different places in parliament, and his moments of relaxation were passed in the most brilliant society. His colloquial powers must have been great; for although he never tasted wine, his approach was hailed with delight by the most debauched wits of the court. Saville said that no man in England should keep him company without drinking but Ned Waller. "It is thought," says Percival Stockdale, "that St Evremond returned to England for the sake of Mr Cowley's company and Mr Waller's."

---

[1] This is probably the woman whom Cromwell appointed to stand sentry over her mother.

[2] The panegyric on Cromwell is partly translated into French verse in Hennet's *Poetique Anglaise*, tom. iii.

His life passed thus agreeably away, until, in 1665, he was urged, by the desire of augmenting his income, now reduced to L.1300 a year, to petition the king for the provostship of Eton College. His application to Charles was successful; but Clarendon refused to affix his seal to the patent, upon the ground that none but clergymen were eligible to the office. Waller had no idea of private friendship being sacrificed to public duty, and this declaration of Clarendon's dissolved an intimacy of ancient date. Two years afterwards, when the chancellor was impeached, Waller's animosity was as fresh as ever, and he rushed among a crowd of assailants to strike an eager and superfluous blow at falling greatness. After Clarendon's banishment, the provostship was again vacant, and Waller again applied for the office; but the highest legal authorities declared that laymen were excluded by the act of uniformity, and the king said that he could not reverse a law of his own making. Some trifling dramatic efforts of Waller's have yet to be noticed. He wrote anew the last act of Beaumont and Fletcher's Maid's Tragedy, altering the catastrophe, and distinguishing his work from that of the confederate dramatists by rhyming verse. Southerne stated to Fenton, that he had seen the Maid's Tragedy acted about the end of Charles's reign, but without Waller's alterations. This is not to be wondered at; for in the heterogeneous condition to which he reduced it, the play was unfit for representation. A mean version of the first act of Corneille's Pompey, of which Lord Buckhurst translated the remainder, is attributed to Waller; and he is said to have been associated with Cowley in the original concoction of that overpraised performance, the Rehearsal.

When James ascended the throne in 1685, Waller was chosen member for Saltash in Cornwall. Being now eighty years of age, he wrote "A Presage of the Ruin of the Turkish Empire, presented to his Majesty King James the Second, on his Birth-day." From the perusal of Tasso, Waller had been inspired with great veneration for the champions of the cross, and feasted his imagination with the childish whimsey of a new crusade. His last poems are on sacred subjects. The chief of these are, "Of Divine Love, a poem in six cantos;" "Of the Fear of God, in two cantos;" "Of Divine Poesy, in two cantos." Having completed this pious task, he began to prepare for death, whose approach he contemplated with a serenity that could not have been expected from him. When life was worth preserving, Waller clung to it with the energy of despair; but when the scene grew dark and comfortless, he quitted it with decent grace. Observing that his legs began to swell, he asked Sir Charles Scarbrough, the king's physician, what that symptom portended. "Why, Sir," said he, "your blood will run no longer." By the appalling disclosure thus abruptly made, Waller was so little terrified that he repeated some lines from Virgil, and went home to await his dissolution, which happened on the 21st of October 1687. He was buried at Beaconsfield, where a monument was erected by the executors of his second son Edmund, who inherited the family estate, his elder brother being a sort of changeling. Besides these, Waller left other three sons.

Waller's character may be partly discovered in his poems. He inquires what ancient bard would not have deduced the pedigree of the first Charles from heaven; the power and piety of Cromwell he traces to the same source. The rising sun, in compassion to the weakness of mortal eyes, "first gilds the clouds," but the full majesty of the merry monarch burst upon his dazzled vision all at once. When this orb of glory is obscured, he pays James the Second the original and appropriate compliment of having restored the golden age. Irritable men are often good-natured, but Waller was equally peevish and malignant. His resentment of contradiction was not found by his associates to be a mere passing cloud; and his conduct to Clarendon demonstrates that revenge was welcome to him, even at the eleventh hour. Atterbury has accused him of literary envy; and the following passage in one of his letters must have been dictated either by malice or stupidity. "The old blind schoolmaster, John Milton, hath published a tedious poem on the fall of man; if its length be not considered as merit, it has no other." Of his shameful timidity enough has been already said. To counterbalance these defects, Waller was a good orator, an elegant poet, and an agreeable companion. It is said that he wished every verse of his expunged that did not imply some motive to virtue. His writings, in that case, would be very much defaced; but he cannot be denied the praise of having written with decorum in a licentious age, and with elegance and smoothness, when the numbers of most of his brother poets were nearly as vicious and irregular as the mode of life which they delighted to illustrate.[1]

WALLINGFORD, a market and borough town of the county of Berks and hundred of Moreton, 46 miles from London. It stands on the river Thames, over which is a fine stone bridge of 19 arches, 300 yards in length, with drawbridges to admit the passage of barges. It is an ancient town, once consisting of twelve parishes, now reduced to four. The corporate body consists of a mayor, four aldermen, and eleven councillors. One member is returned to the House of Commons by the borough. The little trade there is depends principally on the river-navigation. There is a well-endowed free school, four churches, and several chapels for dissenters; also a county-hall, in which the assizes were occasionally held. The markets are on Tuesday and Friday. The population amounted in 1821 to 2493, and in 1831 to 2467

WALLINGTON, a hamlet in the parish of Beddington and hundred of its own name in the county of Surrey, eleven miles from London. It is only remarkable for the printing and bleaching grounds within it, on the banks of the river Wandle. The great rivalry from the calico-printers in the north has suspended the progress of the manufactures of this place. The population amounted in 1821 to 847, and in 1831 to 933.

WALLIS, John, a distinguished mathematician, logician, and grammarian, was born on the 23d of November 1616, at Ashford in Kent, of which parish his father was then minister. Having been previously instructed in the Latin, Greek, and Hebrew languages, he was in 1632 sent to Emanuel College, Cambridge, where he applied himself with great success to various branches of learning. He afterwards removed to Queen's College, of which he was chosen fellow. Having been admitted to holy orders, he left the university in 1641 to act as chaplain to Sir William Darley; and in the following year he accepted of a similar appointment from the widow of Sir Horatio Vere. It was about this period that he displayed surprising talents in deciphering the intercepted letters and papers of the royalists. His adherence to the parliamentary party was in 1643 rewarded by the living of St Gabriel, Fenchurch-street. In 1644 he was appointed one of the scribes or secretaries of the Assembly of Divines at Westminster. During the same year he married Susanna Glyde, and thus vacated his fellowship; but the death of his mother had left him in possession of a handsome fortune. In 1645 he attended those scientific meetings which led to the establishment of the Royal Society. When the Independents obtained the superiority, Wallis adhered to the Solemn League and Covenant. The living of St Gabriel he exchanged for that of St Martin's, Ironmonger-lane; and, as minister of that church, he in 1648 subscribed the remonstrance against putting the king to death. Notwithstanding this act of opposition, he was in June 1649 appointed Savilian professor of geometry at Oxford. In 1654 he there took the degree of M.D. In 1658 he succeeded Dr Langbaine as keeper of the archives. After the restoration, he was confirmed in both his academical offices, and was named one of the king's chaplains in ordinary. He complied with the terms of the act of uniformity, a legislative measure unwise, unseasonable, and unfeeling; but he seems always to have retained moderate and rational notions of ecclesiastical polity. "It hath been my endeavour all along," says this excellent person, "to act by moderate principles, being willing, whatever side was uppermost, to promote any good design for the true interest of religion, of learning, and of the public good." He died at Oxford on the 28th of October 17[illegible]3, in the eighty-seventh year of his age. He "was happy in the enjoyment of a vigorous constitution of body, and of a mind which was strong, serene, and calm." His son John Wallis, who was a barrister, acquired a good estate by his marriage with Elizabeth Harris; and we likewise hear of two daughters, who were both married.

---

[1] The best edition of his works bears the following title, "The Works of Edmund Waller, Esq. in Verse and Prose: published by Mr Fenton." Lond. 1729, 4to.

Dr Wallis was eminently distinguished by the superiority of his talents, as well as by the variety, extent, and solidity of his learning. His works are numerous, and relate to a multiplicity of subjects. Of his scientific genius he has left a conspicuous monument in the collection of his "Opera Mathematica." Oxon. 1697-9, 3 tom. fol. In this collection he did not think it necessary to insert the tracts which he published against Hobbes; because, as he has himself stated, he had no inclination to trample on the ashes of the dead, although it was his duty to expose the fallacious reasoning of that writer when alive. His "Institutio Logicæ," published in 1687, exhibits his proficiency in another department of science. In his "Grammatica Linguæ Anglicanæ" we likewise find many indications of an acute and philosophic intellect. Of this grammar, originally printed in 1653, there are six editions, but the best is that published by Bowyer in 1765. Among various other works, he produced some theological tracts; among which are three dissertations on Melchizedek, Job, and the titles of the Psalms. He was engaged in controversies relative to the doctrine of the Trinity, and to the observance of the Christian Sabbath. In the latter controversy, his antagonist, Thomas Bampfield, a barrister at law, maintained that the Sabbath ought to be observed, not on Sunday, but on Saturday. Nor must the editorial labours of Dr Wallis be overlooked. He published several reliques of the ancient Greek writers on science, and thus established another claim to the regard of his learned contemporaries.

Wallis's *Island*, a small island near the north-east coast of New Ireland, at the entrance of Gower's Harbour, called Isle de Marteaux by M. Bougainville, nine miles north-west of Cape St George. There are other islands of this name, discovered by Captain Wallis in 1767, surrounded by a reef of rocks. Long. 177. W. Lat. 13. 18. S.

WALLSEND, a large village, situated between Newcastle and North Shields, in the county of Northumberland. It is noted for the excellent quality of the coal so abundant in its neighbourhood, as well as for its connection with the celebrated Roman wall built by the emperor Severus, which, as the name of the place indicates, terminated here. There are several building-yards for ships on the banks of the Tyne, and likewise extensive lime-kilns. In addition to the established church of St Peter's, there are several dissenting places of worship. The population of the parish amounted in 1821 to 5103, and in 1831 to 5510.

WALLUBGHUR, a hill-fortress of Hindustan, in the Mahratta territories, in the province of Bejapore and district of Darwar. It was long in possession of the Mahratta chief Purseram Bhow. On his death it was occupied by the Colapoor rajah, in whose possession it remained until 1804, when, by the interposition of the British, it was restored to the peshwa, and is now held by one of his feudatories.

WALMER, a neatly-built village, containing many respectable private dwelling-houses, in the hundred of Cornito in the county of Kent. It is noted for the castle of the same name, built close on the sea-shore, and used as the residence of the lord-warden of the cinque ports. The castle commands an extensive view of the Downs, the Straits of Dover, and the French coast. The population of the parish amounted in 1821 to 1568, and in 1831 to 1779.

WALPOLE, Sir Robert, Earl of Orford, was born at Houghton in Norfolk, September 6th, 1674, and was educated on the foundation at Eton school. Thence he was elected to King's College in Cambridge; but on the death of his elder brother, he resigned his scholarship. He was elected member for Castle-Rising, and represented that borough in the two short parliaments assembled during the last two years of William's reign. In 1702 he was elected for King's Lynn, and represented that borough in several succeeding parliaments. In 1705, he was nominated one of the council to Prince George of Denmark, lord high admiral of England; in 1707, was appointed secretary at war; and in 1709, treasurer of the navy. In 1710, upon the change of the ministry, he was removed from all his posts, and held no place during the remainder of the queen's reign. In 1711 he was expelled from the House of Commons for what they called notorious corruption in his office as secretary at war. The borough of Lynn however re-elected him in 1714; and though the house declared the election void, yet they persisted in the choice. In the well-known debate relating to Steele for publishing the Crisis, he greatly distinguished himself in behalf of liberty, and added to the popularity which he had previously acquired.

On the death of the queen, a revolution of politics took place, and the Whig party prevailed both at court and in the senate. Walpole had before recommended himself to the house of Hanover, by his zeal for its cause, when the commons considered the state of the nation with regard to the Protestant succession; and it is not surprising that his promotion soon took place after the king's arrival. In a few days he was appointed receiver and paymaster-general of all the guards and garrisons, and of all the other land forces in Great Britain, paymaster of the royal hospital at Chelsea, and likewise a privy counsellor. On the opening of a new parliament, a committee of secrecy was chosen to inquire into the conduct of the late ministry, of which Walpole was appointed chairman; and, by his management, articles of impeachment were read against the earl of Oxford, Lord Bolingbroke, the duke of Ormond, and the earl of Strafford. The eminent service which he was thought to have rendered the crown, by the vigorous prosecution of those ministers who were deemed the chief instruments of the peace, was soon rewarded by the extraordinary promotions to the offices of first commissioner of the treasury, and chancellor and under treasurer of the exchequer.

In two years time he resigned all his offices, on account of a misunderstanding which took place between him and the rest of the ministry about certain supplies demanded for the support of his majesty's German dominions. On the day of his resignation he brought in the famous sinking-fund bill, which he presented as a country gentleman, saying that he hoped it would not fare the worse for having two fathers; and that his successor Mr Stanhope would bring it to perfection. His calling himself the father of a project, which has since been so often employed to other purposes than were at first declared, gave his enemies frequent opportunity for satire and ridicule; and it has been sarcastically observed, that the father of this fund appeared in a very bad light when viewed in the capacity of a nurse. In the next session of parliament, Walpole opposed the ministry in every thing; and even Wyndham or Shippen did not exceed him in patriotism. Upon a motion in the house for continuing the army, he made a speech of above an hour long, and displayed the danger of a standing army in a free country, with all the powers of eloquence. Early in 1720 the rigour of the patriot began to soften, and the complaisance of the courtier to appear; and he was again appointed paymaster of the forces, and several of his friends were found soon after in the list of promotions. No doubt now remained of his entire conversion to court-measures; for before the end of the year, we find him pleading as strongly for the forces required by the war-office as he had before declaimed against them, even though at this time the same pretences for keeping them on foot did not exist.

It was not long before he acquired full ministerial power, being appointed first lord commissioner of the treasury, and chancellor of the exchequer; and when the king went abroad in 1723, he was nominated one of the lords justices for the administration of government, and was sworn sole secretary of state. About this time he received another distinguished mark of the royal favour; his eldest son, then on his travels, being created a peer, by the title of Baron Walpole of Walpole. In 1725 he was made knight of the Bath, and the year after knight of the Garter. The measures of his administration, during the long time he remained prime or rather sole minister, have been often canvassed with all the severity of critical inquiry. It is difficult to discern the truth through the exaggerations and misrepresentations of party. He has indeed been accused of employing the sinking fund for the purposes of corruption, of which it was long the fashion to call him the father; but the man who reflects on the transactions of Charles II. and his infamous cabal, will acquit him of the latter part of this charge. He was an enemy to war, and the friend of commerce; and because he did not resent some petty insults of the court of Spain so suddenly as the fiery part of the nation thought he should have done, a formidable opposition was formed against him in the house, which had influence enough to employ in its cause almost all the wit of the nation. Pulteney and Pitt were the great leaders of the party in the House of Commons; while Bolingbroke, and Pope, and Johnson, and almost every man of genius, exerted themselves without doors to enlighten, by pamphlets in prose and verse, the minds of the people, and show the necessity of a Spanish war. This he strenuously opposed, because he knew that the foreign settlements of that power are very remote, and in a climate destructive to Englishmen; and that such of them as we might be able to take, we could not possibly retain. The opposition however prevailed. The nation was indulged in a war of which it surely had no cause to boast of the success; and it is now universally known, that the greater part of those who with honest intentions had, either in parliament or out of it, been engaged to run down the minister, lived to repent of their conduct, and do justice to the man whom they had so pertinaciously vilified.

In order to encourage commerce and improve the revenue, Walpole projected a scheme for an extension of the excise, as the only means of putting a stop to the frauds of merchants and illicit traders. This was another ground of clamour to the orators within and the wits without doors; and while the opposition represented it as a measure big with public mischief, Swift and Pope occasionally alluded to it as an oppression calculated to deprive private life of all its comforts. The minister was therefore obliged to abandon the scheme; but in a succeeding administration it was partly carried into execution, at the express solicitation of the principal persons concerned in that article of trade which it was suggested would be most affected by it; and afterwards the most popular minister that ever directed the councils of this country declared in full senate, that if a time should ever arrive which was likely to render the project feasible, he would himself recommend an extension of the excise laws, as a measure of the greatest advantage to commerce, to the revenue, and to the general interests of the kingdom.

In 1742 the opposition prevailed; and Walpole, being no longer able to carry a majority in the House of Commons, resigned all his places, and fled for shelter behind the throne. He was soon afterwards created earl of Orford; and the king, in consideration of his long and faithful services, granted him a pension of L.4000 per annum. The remainder of his life he spent in tranquillity and retirement, and died in 1745, in the 71st year of his age.[1]

He wrote the following pamphlets. 1. The Sovereign's Answer to the Gloucestershire Address. The sovereign meant Charles duke of Somerset, so nicknamed by the Whigs. 2. Answer to the Representation of the House of Lords on the State of the Navy, 1709. 3. The Debts of the Nation stated and considered, in four Papers, 1710. 4. The thirty-five Millions accounted for, 1710. 5. A Letter from a Foreign Minister in England to Monsieur Pettecum, 1710. 6. Four Letters to a Friend in Scotland upon Sacheverell's Trial; falsely attributed in the General Dictionary to Mr Maynwaring. 7. A short History of the Parliament. It is an account of the last session of the queen. 8. The South Sea Scheme considered. 9. A pamphlet against the Peerage Bill, 1719. 10. The Report of the Secret Committee, June 9th, 1715.

Walpole, *Horace*, the third son of Sir Robert, was born in 1717, became fourth earl of Orford in 1791, and died on the 2d of March 1797, in the eightieth year of his age.

After having been educated at Eton and Cambridge, Horace Walpole passed two years on the continent, the greater part of the time being devoted to Italy, where he acquired that taste for art which afterwards furnished the main employment of his life. In the autumn of 1741, he returned to England; and he took his seat in the parliament which, meeting in the end of that year, drove his father from power before the close of its first session. He continued to be a member of the House of Commons for twenty-six years, retiring at the age of fifty-one. His political career was by no means distinguished. We do not hear of his having delivered more than three speeches in all, and of these the two that have been preserved exhibit no great talent for oratory. For political business he possessed neither industry nor ambition; and the character in which he appeared throughout was little more than that of a spectator, who took greater pleasure in watching the acts of others, and recording his own impressions in regard to them, than in endeavouring himself to act either for his own benefit or for that of others.

As an observer of public men, however, he never allowed his attention to flag; and his observations were most diligently set down in a multifarious correspondence with friends, and, for a part of his life, in political memoirs, avowedly intended for publication when the writer and his contemporaries should have quitted the scene. Politics, however, like all things else, were for Horace Walpole nothing more than an amusement. Literature, art, and antiquities ministered by turns to the same end, although all these pursuits were followed in the same careless and Epicurean spirit. But his pen never lay long idle; few themes that demanded but little study for their treatment proved alien to it; and among his works there gradually accumulated, not only an immense mass of letters, as evidently calculated for publication as any thing else he ever wrote, but specimens of his aptitude for the composition of novels, of dramas serious and comic, of political tracts and satires, of grave historical disquisitions, of memoirs for the history of English art and of English aristocratic literature, and of those light verses which may be written by gentlemen having but slender pretensions to the name of poets.

---

[1] Coxe's Memoirs of the Life and Administration of Sir Robert Walpole, Earl of Orford. Lond. 1798, 3 vols. 4to. An admirable view of the character and policy of this illustrious statesman will be found in the Edinburgh Review, No. cxliii.

Walpole's circumstances however allowed him to indulge, in a more dignified fashion, his taste for art and literature. One who was ashamed of writing plays and poems, had no need to be ashamed of collecting books and antiques, or of building baronial castles, and designing romantic gardens. Although Sir Robert Walpole himself left his affairs exceedingly embarrassed, he had carefully provided for the younger branches of his family by grants of public posts. Several sinecure offices conferred on Horace made up his income, during the greater part of his life, to L.4000 at least or perhaps considerably more. To a bachelor, sufficiently methodical and cautious in money-matters, a sum like this offered no inconsiderable facilities for the indulgence of one or two expensive tastes. Walpole began to collect a few antiques while in Italy; but his passion for collecting did not arrive at its height till much later. In 1747, when he was thirty years old, he purchased a cottage and piece of ground at one end of the village of Twickenham. Subsequent purchases increased the domain to an extent of several acres, the whole of which was laid out as pleasure-grounds; and the "little plaything house," incessantly altered and enlarged, grew at length into the Gothic castle of Strawberry Hill. Its owner's taste had received, partly perhaps from his friend Gray, an early direction towards this style of architecture, as well as to the branches of antiquarian study connected with it.

In the erection and decoration of his mansion, in desultory study and composition, in the enjoyments of society which embraced many of the aristocracy, and a very few of the literary men of the country, and in several excursions to Paris, which introduced him to the philosophical precursors of the revolution,—in employments such as these, varied only by his retirement from parliament, passed the life of Horace Walpole, till he had attained his seventy-fourth year. The death of his unfortunate nephew then gave him his father's earldom, an honour unaccompanied by any substantial accession of fortune. He had for many years been a victim of gout, and the short remainder of his life was spent in utter helplessness of body. But the mind was unshaken to the last.

The works in which Walpole exhibits most characteristically all his qualities of mind, both moral and intellectual, are his Letters, especially those in which the politics of the country are the matters chiefly handled. Accordingly his correspondence with Sir Horace Mann (which was prudently suppressed till the present generation) may be most advantageously studied as a likeness of the writer; and to this interesting series other sets of letters, such as those to the Conways, and even the posthumous Memoirs, may be regarded as little else than supplementary. The dissection of motives, which is the task undertaken with the greatest readiness, is that which is performed least satisfactorily. The analysis of the springs of action is often evidently just; but as often it is clearly performed by one who was incapable alike of believing that men whom he disliked could act patriotically or nobly, and of even conceiving that any party or any individual could be actuated by motives of a higher class than those by which, unconsciously in part, he himself was led. The selfishness of Strawberry Hill, though not its refinement, was indeed a fair enough measure by which to estimate such statesmen as the Pelhams: but both the selfish indolence and the confined though acute intellect were utterly alien to the mind of Pitt, and utterly incapable of estimating him and the few other spirits which in that age of intrigue and detail possessed real strength and elevation. Akin to this temper of universal censoriousness, and indeed springing from the same source, is another distinctive peculiarity of all Walpole's political sketches; namely, his incapacity for determining the relative importance either of principles or actions. An intrigue which substitutes in the ministry a Holdernesse for a Pelham, possesses in his eyes equal consequence with the agitation which decides whether the foreign policy of the nation is to be swayed by strength and patriotism or by weakness and corruption—by William Pitt, or by the creatures who, during the greater part of his life, thwarted and crippled his exertions. Nay, the politics of the day themselves appear, in Walpole's eyes, as standing on the same level with the amusements, the family history, the debauchery of the fashionable world: Lady Orford is satirized in the same breath with the Chancellor Hardwicke, and the king of Prussia is not less a theme of merriment than "Prince Pigwiggin" or the duchess of Kingston.

These very qualities, which at once bear unfavourable witness to the state of the writer's mind, and diminish the value of the writings as historical documents, do nevertheless give a peculiar attraction to them as literary compositions of a certain class. The class is not a high one, but in it the best parts of this Correspondence occupy the very foremost place. The Letters are inimitable pictures of society and of human character, drawn by the hand of one who was a master in the delineation of scenes from familiar life; not, it is true, inspiring his figures with poetic truth or serious significance, but shedding over all of them a gaily comic light. They are a kind of satires, and few compositions claiming that name are equal to them in lively wit, in striking grasp of character, in picturesque colouring of incidents, and in apposite, epigrammatic, vigorous language. They have been criticised at great length, and with consummate talent, in the Edinburgh Review, vol. lviii.

WALSALL, a town of the hundred of Offlow and county of Stafford, 116 miles from London and fifteen from Stafford. It is a place of great antiquity. It stands on the side of a hill, and consists of several regular and spacious well-built streets, which are well paved, and lighted with gas. The parish church is a spacious building, in the form of a cross, with an octagonal tower. There is also a handsome chapel, called St Paul's, erected in 1826. The town has a well-supplied market on Tuesday, and three annual fairs. The trade is very extensive, chiefly in various kinds of hardware, but especially in what consists in horses' furniture, usually called saddlers' ironmongery. The government is vested in a corporate body, consisting of a mayor, six aldermen, and seventeen councillors. The suburb, called the Foreign, is now the largest portion of the place, or at least contains the greatest number of inhabitants; and by the late act the whole is made one borough for the purposes of election, and has received the power of returning one member to the House of Commons. Walsall contains many dissenters, who have their respective chapels. The population amounted in 1821 to 11,914, and in 1831 to 15,066.

WALSH, **William**, an English critic and poet, the son of Joseph Walsh, Esq. of Abberley in Worcestershire, was born about the year 1660. He became a gentleman commoner of Wadham College, Oxford, but left the university without taking a degree. His writings are to be found among the works of the Minor Poets, printed in 1749. He was

Walsham || Walsingham.

made gentleman of the horse in Queen Anne's reign, and died in 1708. He was the friend of Dryden and of Pope, the former of whom esteemed him the best critic then living; and Pope has celebrated his character in the Essay on Criticism.

WALSHAM, North, a market-town of Norfolk, in the hundred of Tunstead, 124 miles from London, and twelve from Norwich. It is about six miles from the sea-shore, and consists of three streets, diverging from a central area, in which is built the church. It has a well-supplied market on Tuesday, and two annual fairs. There is an endowed free school, and several dissenting places of worship. The population amounted in 1821 to 2303, and in 1831 to 2615.

WALSINGHAM, a market-town of the county of Norfolk, in the hundred of North Greenhoe, 117 miles from London, and four miles from the sea. It was formerly a large place, when the abbey, whose ruins remain to attest its former magnificence, contained an image of the Virgin Mary, much venerated, and visited by numerous pilgrims, and to which Henry VIII. once repaired barefooted, with the present of a valuable necklace. The reformation caused the town to decline. It has now a handsome church, and a good market on Friday. The country around it is highly fertile, and especially yields abundance of saffron. The population amounted in 1821 to 1067, and in 1831 to 1004.

Walsingham, *Thomas*, an English Benedictine monk of the monastery of St Alban's, who lived about the year 1440. He applied himself to the history and antiquity of his country, in quality of historiographer to the king, and composed the History of King Henry VI., with other works.

Walsingham, *Sir Francis*, secretary of state during the reign of Queen Elizabeth, was descended from an ancient family in Norfolk, but was born at Chislehurst in Kent, in the year 1536. After having made great progress in his studies at Cambridge, he was twice sent ambassador to France, and at his return to England was employed in the most important affairs, became secretary of state, and was one of the commissioners for the trial of Mary queen of Scotland. Sir Francis was undoubtedly one of the most refined politicians and most penetrating statesmen that any age has produced. He had an admirable talent, both in discovering and managing the secret recesses of the heart. He had his spies in most courts in Christendom, and allowed them a liberal maintenance; for it was his maxim, that knowledge cannot be bought too dear. In 1587, the king of Spain having made vast preparations, which surprised and kept all Europe in suspense, Walsingham employed his utmost endeavours for the discovery of that important secret; and accordingly procured intelligence from Madrid that the king had informed his council of his having despatched an express to Rome, with a letter written with his own hand to the pope, acquainting him with the true design of his preparations, and begging his blessings upon him; which design for some reasons he could not disclose till the return of the courier. The secret being thus lodged with the pope, Walsingham, by means of a Venetian priest, whom he retained at Rome as a spy, got a copy of the original letter, which was stolen out of the pope's cabinet by a gentleman of the bed-chamber, who took the key out of the pope's pocket while he slept. After this, by his dexterous management, he caused the Spaniards' bills to be protested at Genoa, which should have supplied them with money for their extraordinary preparations; and by this means he happily retarded this formidable invasion for a whole year. In short, he spent his whole time and faculties in the service of Queen Elizabeth, on which account her majesty was heard to say, " that in diligence and sagacity he exceeded her expectations." However, after all his eminent services to his country, this man gave a remarkable proof at his death, which happened on the 6th of April 1590, how far he preferred the public interest to his own; he being so poor, that, excepting his library, which was a very fine one, he had scarcely effects enough to defray the expense of his funeral.

WALTHAM ABBEY, a market-town of the county of Essex, in the hundred of Waltham, eleven miles from London. It takes its name from the stately abbey erected there by Harold, son of Earl Godwin, and afterwards further endowed by Henry II. The present church was formed out of a part of the ancient building. The town has a market on Tuesday, and three annual fairs. An establishment has been formed by government for the manufacture of gunpowder. The population amounted in 1821 to 1883, and in 1831 to 2013.

WALTHAMSTOW, a large parish, with a town of the same name, in the county of Essex, in the hundred of Becontree, five miles from London. It is situated near the river Lea, in a rich district, and consists mostly of country houses belonging to the rich class of traders of the metropolis. There is a large church, an endowed school, and several dissenting chapels. The population amounted in 1821 to 4304, and in 1831 to 4258.

WALTON, Isaac, an early writer of great popularity, was born on the 9th of August 1593, in the parish of St Mary and town of Stafford. The condition of his father is not mentioned, but his mother is described as the daughter of Edmund Cranmer, archdeacon of Canterbury, and the niece of the archbishop. His own occupation was that of a shopkeeper; but his love of literature, as well as his upright and amiable simplicity of character, recommended him to the favour and friendship of many individuals distinguished by their talents and station. In 1624 we find him residing on the north side of Fleet-street, two doors west of Chancery-lane; and in 1632 he had removed to a house in the lane. The tradition of his family represented him as a Hamburg merchant, or wholesale linen-draper; but, according to Anthony Wood, he followed the occupation of a sempster. He married Anne the sister of Thomas Ken, afterwards bishop of Bath and Wells. While an inhabitant of St Dunstan's in the West, he was a regular attendant on the ministrations of Dr Donne, then vicar of the parish; and with this witty poet and divine he contracted a friendship, which was only terminated by death. Walton visited him in his last sickness, and wrote a circumstantial account of his life, which in 1640 accompanied a collection of the dean's Sermons. Another of his distinguished friends was Sir Henry Wotton, whose life he also undertook to write, and finished it about the year 1644. It was prefixed to the " Reliquiæ Wottonianæ," which he edited in 1651. It is to be regretted that he did not execute his design of writing the lives of other two individuals connected with Eton, Sir Henry Savile and John Hales, both very eminent in their generation. About the year 1643, we are informed, he left London, and, with a fortune very far short of what would now be called a competency, seems to have retired altogether from business. While he resided in the metropolis, angling had been his favourite recreation, and in that art he arrived at great skill and proficiency. The result of his experience he embodied in a very pleasing volume, entitled " The complete Angler, or contemplative Man's Recreation." Lond. 1653, 8vo. This work was so favourably received, that other four editions were published during the author's lifetime, namely, in 1655, 1664, 1668, and 1676. To this last impression a second part, containing instructions how to angle for trout or grayling, was added by his friend Charles Cotton. Of both parts there are many subsequent editions, and the popularity of the work continues unimpaired. An elaborate edition, with a life of the author, was published by Sir John Hawkins in the year 1760. Walton having resumed his biographical labours, published the life of Hooker in 1662, that of Herbert in 1670, and that of Sanderson in

167 His Lives were afterwards collected together, and in this form have repeatedly been printed. An edition, containing an account of the author, together with annotations, was published by Dr Zouch. York, 1796, 4to. The work, thus illustrated, reached a third impression. York, 1817, 2 vols. 8vo. These specimens of circumstantial biography are rendered very interesting by the native kindness of the author's disposition, and by the garrulous simplicity of his narrative. In 1680 he published, but without his name, "Love and Truth: two modest and peaceable Letters, concerning the Distempers of the present Times: written from a quiet and conformable Citizen of London, to two busie and factious Shopkeepers in Coventry." Lond. 1680, 4to. This tract was reprinted in Dr Zouch's edition of the Lives. At the age of ninety, he edited "Thealma and Clearchus; a Pastoral History in smooth and easie verse: written long since by John Chalkhill, Esq^{r}. an acquaintant and friend of Edmund Spencer." Lond. 1683, 8vo. As to the author, he states "that he was in his time a man generally known, and as well beloved; for he was humble, and obliging in his behaviour, a gentleman, a scholar, very innocent and prudent; and indeed his whole life was useful, quiet, and virtuous." Of this poem there is a recent edition. Chiswick, 1820, 12mo. The name of Chalkhill is otherwise so entirely unknown, that Mr Singer, who published this edition, is inclined to doubt whether the poem may not have been a youthful production of its first editor. Having attained to a healthful and happy old age, he died on the 15th of December 1683, at Winchester, in the prebendal house of his son-in-law Dr Hawkins, and was interred in the cathedral of that city. His wife died in 1662. Their son Isaac Walton having been educated at Oxford, became rector of Polshot, and canon residentiary of Salisbury. He died unmarried, in the year 1716. His only sister Anne was married to William Hawkins, rector of Droxford, and prebendary of Winchester. Their only son, William Hawkins, was the author of a well-known "Treatise of the Pleas of the Crown." (x.)

WALTON, *Bryan*, a very eminent biblical scholar, was born in the year 1600, at Seymour in the district of Cleveland in Yorkshire. He is said to have been admitted a sizar of Magdalene College, Cambridge, in the month of July 1616. In 1618 he became a sizar of Peter House. He took the degree of A. B. in 1619, and that of A. M. in 1623. He left the university for a curacy and the mastership of a school in Suffolk. He next removed to the metropolis, as an assistant at the church of Allhallows Bread-street; and in 1626 he was collated to the rectory of St Martin's Orgar. On the 15th of January 163[illegible]-6, he was instituted to the rectories of St Giles-in-the-fields, and of Sandon in Essex. The former he does not appear to have retained. About this time, he is supposed to have been chaplain to the king, and to have been collated to a prebend of St Paul's. In 1639 he took the degree of D. D. at Cambridge; and in the public act, he maintained a thesis against the infallibility of the pope. His wife, Anne Claxton, died in the course of the following year.

Dr Walton was involved in the troubles which ensued; and in 1641 he is supposed to have been dispossessed of both his rectories. Towards the close of the year 1642 he was ordered into custody as a delinquent. Like many other members of his order, he afterwards sought a place of refuge at Oxford; and on the 12th of August 1645 he was incorporated doctor of divinity. Here, among the learned fugitives, he met with Dr Fuller, dean of Ely, whose daughter Jane became his second wife. On his return to London he resided in the house of his father-in-law. Undismayed by the change of his circumstances, he planned and executed one of the greatest, if not the very greatest, literary enterprise of which his country can boast. This was the famous Polyglott Bible, of which the plan appears to have been brought to considerable maturity in the year 1652. The design was approved by the Council of State, who exempted from duty all the paper to be employed in the edition; and to the credit of the age it must be recorded, that in the month of May 1653 subscriptions had been obtained to the amount of L.9000. Dr Walton had various coadjutors, but the very laborious task of editorship devolved upon himself. As a precursor, he published "Introductio ad Lectionem Linguarum Orientalium." Lond. 1654, 8vo. This introduction was reprinted at London in 1655. The great work itself was completed in the space of about four years, and made its appearance under the title of *Biblia Sacra Polyglotta*, &c. Lond. 1657, 6 tom. fol. In this edition, nine languages are employed, but not a single book is printed in so many. The four evangelists are in six, the other books of the New Testament only in five, and those of Judith and the Maccabees only in three. The Prolegomena have been repeatedly printed in a separate form, and are allowed by the most competent judges to be a work of great erudition, as well as of great value. The last edition is that of Wrangham, published at Cambridge in 1825, in 2 vols. 8vo.

Among those who assisted Walton in his very arduous undertaking, we must first of all mention the venerable Archbishop Usher, who not only aided and directed him by his counsel, but likewise furnished him with a collation of sixteen manuscripts. His learning was so variegated and so profound, that it was of no small importance for the editor to have access to him on all occasions of doubt and difficulty. Another able coadjutor was Dr Lightfoot, and a third was Dr Pocock. The services of Abraham Wheelock, Patrick Young, Dudley Loftus, Herbert Thorndike, Thomas Hyde, Thomas Greaves, and several other individuals, are likewise commemorated. Selden, who possessed a great fund of oriental learning, was a zealous promoter of the design; and he joined with Usher in signing a recommendation, which was printed with the prospectus. He was one of those to be consulted in the progress of the work, and his valuable library was open to the editor.

One fellow-labourer, Edmund Castell, demands a more particular notice. He not only rendered important assistance to Walton, but likewise compiled a most learned and elaborate work, which is always regarded as a necessary accompaniment of the Polyglott. It was published under the title of "Lexicon Heptaglotton, Hebraicum, Chaldaicum, Syriacum, Samaritanum, Æthiopicum, Arabicum, conjunctim; et Persicum separatim," &c. Lond. 1669, 2 tom. fol. This Lexicon is a work of stupendous labour; and, according to Dr Clarke, it "is probably the greatest and most perfect work of the kind ever performed by human industry and learning." He was aided by Dr Lightfoot, and by some other orientalists, one of whom was Beveridge, and another Golius. In the preparation of this work, and in labouring at the Polyglott, Dr Castell spent seventeen years, and generally sixteen or eighteen hours a day. In the progress of his work, he maintained in his own house seven Englishmen, and seven foreigners, in the capacity of copyists. He spent the large sum of L.12,000, and contracted debt to the amount of L.1800; and the recommendations of the king and the archbishop of Canterbury only procured him contributions to the amount of L.700. "Though I perish," said this learned and excellent person, "it comforts me not a little to see how holy writ flourishes." He was not however left to perish. At the time of his death, which occurred in 1685, he was professor of Arabic in the university of Cambridge, prebendary of Canterbury, rector of Higham Gobion in Bedfordshire, and chaplain in ordinary to his majesty.

Dr Walton's next publication bears the title of "Dissertatio, in qua de Linguis Orientalibus, Hebraica, Chaldaica, Samaritana, &c. et de Textuum et Versionum quæ in Complutensibus, Regiis, Parisiensibus et Anglicanis Polyglottis Bibliis habentur, Antiquitate, Authoritate et Usu, breviter disseritur." Daventriæ, 1658, 12mo. This is followed by Wower's "Syntagma de Græca et Latina Bibliorum Interpretatione." His meritorious labours were not duly appreciated by some of his contemporaries; and he was very unadvisedly attacked by Dr Owen, in "Certain Considerations on the Prolegomena and Appendix to the late *Biblia Polyglotta*." The writer was himself a man of learning; but the dangers which he contemplated were imaginary, and he ventured upon ground which he could not maintain against such an antagonist. His work was very ably refuted by Dr Walton, in "The Considerator considered." Lond. 1659, 8vo.[1]

At the period of the Restoration, his great and conspicuous merits could not be disregarded. He was speedily restored to his former preferments, and was nominated to the bishopric of Chester. On the 2d of December 1660, he was consecrated in Westminster Abbey. In March following he was one of the commissioners at the Savoy conference; a conference which so strikingly displayed the unmitigated bigotry of the triumphant churchmen. The bishop of Chester however appears to have acted with sufficient moderation. His new honours were very short and fleeting. He reached his episcopal seat on the 11th of September 1661; and having soon afterwards returned to London, he died there on the 29th of the ensuing November, in the sixty-second year of his age. (x.)

WALTON-ON-THAMES, a town of the county of Surrey, in the hundred of Elmbridge, eighteen miles from London. Its name denotes its situation; and there is a bridge over the river, near to which are the remains of an ancient bridge, said to have been erected by Julius Cæsar, who is reported to have passed the stream by it. There are many fine seats in the parish and vicinity, especially Oatlands, the residence of the late duke of York. The population amounted in 1821 to 1891, and in 1831 to 2035.

WALURU, a town of Hindustan, province of Mysore. It consists of 500 houses, and is one of the richest and best built towns on this frontier, above the Ghauts. It is defended by a citadel, and has a manufacture of cotton cloth, and another of blankets. There are also distilleries of country rum, in which the bark of the mimosa is an ingredient. A Hindu chieftain, who formerly held this town and the adjoining territory, is allowed to inhabit the citadel, and has a pension from the Mysore government. It is situated a few miles from Bangalore.

WAMAR, a small island in the Eastern Seas, near the west coast of Aroo. Long. 134. 57. E. Lat. 5. 30. S.

WANDIA, a town of Hindustan, province of Cutch, district of Wagur, situated on the northern side of the Runn, immediately opposite the fortress of Mallia. It was subdued by the British in 1809, when the chief was laid under tribute. Long. 70. 43. E. Lat. 23. 3. N.

WANDICOTTA, a town and large district of the Balaghaut ceded territories, situated principally between the fourteenth and fifteenth degrees of north latitude, and now mostly comprehended in the Cudapah collectorship. The chief towns are Wandicotta, Tadimery, and Anantapooram, and the principal river is Pennar. The town was formerly a very strong fortress, and remarkable for the vicinity of a diamond mine. It is fifty miles north-north-west from Cudapah. Long. 78. 20. E. Lat. 14. 42. N.

WANDIPOOR, a town and fortress of Hindustan, province of Bootan, in the territories of the rajah. It is a place of great strength, being situated on the narrow extremity of a rock, between three rivers, the confluence of whose streams takes place at its sharpened point, and forms a river of considerable magnitude, called the Chantchieu, which falls into the Brahmapootra. At Wandipoor there is a curious bridge of fir, without the least iron in its construction, of 112 feet span, which is said to have lasted 150 years, without exhibiting any symptoms of decay. The climate here is excessively cold, and subject to high winds. The town is consecrated, and is the residence of a considerable number of gylongs or priests of the grand lama.

WANDIWASH, a town and fortress of the south of India, in the province of the Carnatic. In 1759, the British were repulsed in an attack on this place; but in November following, it was taken by Sir Eyre Coote, with scarcely any loss. It was the scene of a decisive battle, in January 1760, between the French under M. Lally, and the British under Colonel Coote, with their respective allies, in which the former were totally defeated. The fortress was demolished, by order of General Stuart, in 1783. The town, with the adjoining territory, is now included in the Arcot collectorship. It is sixty-four miles south-west of Madras. Long. 79. 40. E. Lat. 12. 20. N.

WANDSWORTH, a town and large parish in the county of Surrey, in the hundred of Brixton, six miles from London. It stands at the junction of the river Wandle with the Thames, and contains corn-mills, distilleries, breweries, and boat-building yards upon a large scale, as well as silk and printing works. There are two churches, one of recent erection, some dissenting places of worship, and some charitable establishments founded by Henry Smith, who was buried here in 1627, having left vast sums for benevolent purposes. There are many fine houses within the parish. The population amounted in 1821 to 6702, and in 1831 to 6879.

WANKANEER, a town of Hindustan, province of Gujerat, situated on an angle formed by the conflux of the rivers Muchoo and Patalia. It contains about 5000 houses, and a very handsome mosque, and belongs to a petty chief, who is tributary to the Guicowar. Long. 70. 55. E. Lat. 22. 27. N.

WANLOCKHEAD, a village in the parish of Sanquhar and county of Dumfries, nearly 1500 feet above the level of the sea. It is famed for the lead mines which have been worked there from the middle of the sixteenth century to the present time, with various success, but which are now on the decrease. Gold was at one time worked for, and it is still collected by the miners in small particles. Between the years 1831 and 1835, two specimens were found which weighed respectively ninety and sixty grains. The quantity of lead raised in 1829 was 596 tons, and in 1830, 461 tons, which was sold at L.13 per ton. The number of persons employed in the works in 1835 amounted to 208. The miners have established a subscription library for their own use. The population amounted in 1821 to 706, and in 1831 to 675.

WANNY, an extensive district in the island of Ceylon, situated on the north-east quarter, in the vicinity of Trincomalee. It is a flat country, well adapted for the cultivation of rice.

WANSTEAD, a parish of the county of Essex, in the hundred of Becontree, six miles from London. It is a scattered place, containing many fine residences belonging to the richer class of the inhabitants of the metropolis. It was chiefly remarkable for the magnificent mansion recently destroyed, to the great regret of the public. The church is a modern elegant edifice. The population amounted in 1821 to 1354, and in 1831 to 1403.

WANTAGE, a market-town and parish of the county of Berks, and in the hundred of the same name, sixty miles from London. This place is celebrated from King Alfred having been born in a royal residence which it once contained. The town stands in the vale of the White Horse; a name given to it from the figure of a gigantic horse cut in the side of a chalk-hill, to commemorate Alfred's victory over the Danes. It is in a galloping position, and covers nearly an acre of ground. Near to the horse are some stones set on edge, said to be the burial-place of the Danish leaders who fell in the battle, which, according to the tradition, was fought near it. The peasantry in the neighbourhood are accustomed to assemble yearly at midsummer for what is called *scouring the horse*, when they remove every weed and obstacle that may have obscured the figure, and afterwards spend the day in various rural sports. It is now a place of little trade, except that of making flaxen cloth for sacking. There is a market on Saturday, and four annual fairs. The population amounted in 1821 to 2560, and in 1831 to 2507.

---

[1] This work forms the second volume of Todd's Memoirs of the Life and Writings of Brian Walton, D. D. Lord Bishop of Chester. Lond. 1821, 2 vols. 8vo.

WAPENTAKE is the same with what is called a *hundred*, especially used in the north counties beyond the river Trent. The word seems to be of Danish original, and to be so applied for this reason: when first the kingdom, or a part, was divided into wapentakes, he who was the chief of the wapentake or hundred, and who is now called a *high constable*, as soon as he entered upon his office, appeared in a field on a certain day on horseback with a pike in his hand, and all the chief men of the hundred met him there with their lances, and touched his pike; which was a sign that they were firmly united to each other by the touching their weapons. But Sir Thomas Smith says, that anciently musters were made of the armour and weapons of the several inhabitants of every wapentake; and from those that could not find sufficient pledges for their good bearing, their weapons were taken away and given to others; from whence he derives the word.

WAPPING. See LONDON.

WAR.

That portion of military science which falls to be treated under this term, may be conveniently discussed, in a work like the present, under the two main and obvious divisions of War by Land, and War by Sea. We shall accordingly view the subject with reference to these divisions.

PART I.—WARLIKE OPERATIONS BY LAND.

Referring generally to the articles ARMY, ARTILLERY, FORTIFICATION, and GUNNERY, for much that, in a large view belongs to the science of war, we shall under this division of the present head direct our attention to the great principles of war; and shall endeavour to give as full a view of their applications and combinations as our limits will allow.

Jomini has demonstrated that the art of war reposes upon one governing principle, or what may be termed the fundamental maxim; by the application of which all the combinations are good, and without which they are all faulty. This maxim consists in effecting, with the greatest mass of forces, a combined operation upon the decisive point. To illustrate the subject, it may be observed, that the decisive point in war, or what has been termed the primitive objective point, is obviously that in which resides the principle of strength in an enemy; and it follows, that to be able to destroy it in the shortest and most effectual manner, must be the fundamental principle adopted by his antagonist. The mode of effecting this purpose is however the difficult part of the question, because of the infinite variety of circumstances to which it is subjected. But the theory of war may nevertheless be divided into three primitive combinations; because the practice is composed of as many branches, each of which depends upon particular principles: therefore, a great operation, to be perfect, ought to include the three primitive combinations; because then they produce the complete application of the fundamental maxim. The first of these relates to what is commonly termed forming the plan of a campaign, and consists, either in an offensive or defensive view, in the art of embracing the lines of operations in the most advantageous manner. The second is the art of moving the mass of forces, in the most rapid manner possible, upon the objective point of the primitive or accidental line of operations. This is the method of execution, or strategy. The third is the art of combining the simultaneous application of the mass of forces on the most important point of a field of battle. This branch is usually designated by the term Tactics.[1]

I.—PLAN OF CAMPAIGN.

A plan of campaign depends upon six essential considerations: 1st, the political situation of both parties; 2d, the situation of the moment; 3d, the relative force and military means; 4th, the location and distribution of the armies; 5th, the natural line of operations; 6th, the most advantageous line of operations. In forming the plan, it is not necessary to have regard solely to the exact balance of the relative means of war between the parties, but to view them only as they are important. Territorial and manœuvring lines of operations are the principal object; and though they are subject to many accessory considerations, the rules of the art must nevertheless form their basis. Originality and great boldness are not incompatible with their application; such, for instance, as the plan which Napoleon, in 1800, executed in Italy. No enterprise could be more daring, none more rich in great and decisive combinations, or more prudent and cautious; since, while it menaced the enemy with ruin, no greater misfortune could occur, in case of check, than the sacrifice of the extreme rear-guard.

Before we proceed, it may be useful to fix, by definitions, several terms, upon the comprehension of which the most important military reasoning depends.

By *a base or basis of operations* is meant a frontier, the course of a river, a coast, a range of mountains or fortresses, or any topographical or political extent of country, upon the imaginary line of which the corps of an army assemble, offensively, to take their departure from thence into the enemy's country, and towards which, in case of failure, it is intended to retreat; defensively, to counteract all the measures which an invading force may pursue.

Lines of operations are divided into territorial and manœuvring lines. By *territorial lines* are understood those which nature or art has traced for the defence or invasion of states. Frontiers covered by fortresses, or defended by nature with chains of mountains, great rivers, or other obstacles, form their constituents. *Manœuvring lines* are the dispositions of the general to traverse them offensively, or cover them defensively. Both these lines of operations are intimately connected. In offensive war, the line is an imaginary perpendicular upon the base, along which an army operates against the enemy; in defensive war, it is often the same, but still oftener parallel to the territorial line. *A line of communication* is either the same as that of operations, or any other by which the army receives its supplies, and communicates with the base.

---

[1] For the sake of perspicuity, when this term is applied to the instruction of troops, it should be distinguished by the qualifying adjective, *Elementary Tactics*. Thus also the phrases, science, and art of war, are used as synonymous, while we should understand by the science of war the knowledge of the theory of all its elements; and by the art of war, the skilful application of that knowledge.

Some examples will render the definitions more intelligible. France and Austria have three great lines of operations against each other; by Italy on one side, Switzerland and Tyrol in the centre, and by Germany on the other. In these the Po, the Maine, the Danube, or a principal road, constitutes the *matériel* of lines; which are amenable to only a few rules prescribed by their nature. Between Prussia and Austria again are three lines, through Moravia, Lusatia, and Saxony. Lines of operations are divisible into collateral or separate points. Frederick entered Bohemia by his central line, upon four points. The French invaded Germany in 1796 and 1799 upon two subdivided lines. Napoleon always operated upon one principal line, as did the duke of Wellington in Spain.

Thus far no great variety of combinations seems to perplex the view; but in the selection of the particular line, the problem becomes difficult, because a great multiplicity of circumstances, many of them not purely military, interpose. The political situation of the belligerents; their relative resources; character and situation of the fortresses; accidental strength of their forces; distance by sea; course of a considerable river; direction of a chain of mountains; nature of the country; political state of either party; jealousy of a neutral, or apprehensions of an ally; all in their turn claim consideration. In general, however, the initial application of military masses should be, when the belligerents are neighbours, upon some part of the frontier which projects into the hostile state, as Bohemia with regard to Prussia, or Silesia with regard to Austria. But it is a maxim that lines of operations have their key as well as fields of battle: in the former, the great strategical points are decisive; as, in the latter, the points which command the weak part of a position constitute the key. Where there exists a vast superiority of force on one side, the key, or great strategical point, may be sought at a considerable depth in the line of operations; but where the masses are nearly balanced, it is necessarily reduced to a relative proportion with the breadth of the base. Thus, for instance, the destruction of a French army on the frontier of the Netherlands, would not immediately produce the consequence of the victors marching to the capital, unless they had sufficient superiority to mask the principal fortresses which cover her line of defence in that quarter, or some other accidental circumstance rendered such a measure practicable. As further proofs of the relative proportion between the depth and base of a line of operations, that of Napoleon in Russia failed on both its pivots, before the summit was defeated; and those in Spain, although they were supported by intermediate fortresses, immediately contracted, when the battle of Salamanca produced consequences which endangered the western communication with the base.

Although it is absolutely necessary to move with a mass of force near the enemy, it is more advantageous to march in separate corps while still at a distance from him, if he has not a concentrated mass ready to act, and there be several roads leading concentrically towards the point intended to be occupied. It is evident that five corps, of twenty thousand men each, will move forward more rapidly towards any point, than a hundred thousand men, marching on the same road, who can only advance with the tardiness inherent in large bodies, and besides are encumbered with the immense train of their subsistence. Celerity of movement, multiplying the force of an army by enabling the mass to be carried alternately upon every point of the line, is an advantage of invaluable consequence; but this is not the only reason for recommending this method. There are two others, viz. the increased facility of subsistence, and the uncertainty into which it throws the enemy.

An army of 20,000 men can find subsistence, in central Europe, on every part of their march, by merely causing the country within some leagues to contribute to their wants; and if they convey with them biscuit for eight or ten days, that is, during the first period, while corps are in position, or manœuvring in a contracted area with other columns, they will be enabled to subsist till the magazines are formed. Thus military operations are in a great degree emancipated from the necessity of pre-arranged magazines, and the regular encumbrance of field-ovens.

The army which commences offensive operations takes the lead in all the movements, and those of the enemy are necessarily subordinate to them. If therefore it occupies with a corps each of the great avenues leading to the enemy, he will be in a state of uncertainty along his whole line of defence or operations, and remain in suspense as to the point upon which he ought to collect his masses to oppose them. Upon these facts, the following series of maxims is founded

1. When an army undertakes an invasion, or acts offensively, it takes the lead (or, as the French term it, *l'initiative*) in the movements.

2. This advantage precludes the necessity of marching in mass, until near the point where the enemy is to be found and attacked. Until then it is preferable to move in several strong corps, in proportion to the collective strength of the army, and to direct them upon the communications which lead concentrically to the point.

3. The general direction can only be upon the centre, one of the extremities, or the rear, of the hostile line. An extremity will usually be found most eligible, because from that point the rear is easily attained; the centre only in the case where the enemy's line is scattered, and his corps separated by great intervals.

4. In this case the greater number of the corps should advance upon one of the isolated parts, and endeavour to surround it, while the remainder should occupy a central point to keep the rest of the hostile army in check.

5. When the principal mass of these corps is directed into the rear of an enemy, by passing one of the extremities of his line, one corps should remain upon that extremity, in order to keep open the communication with the line of operations, while the opponent is cut off from his. This corps serves likewise to attack him in flank, and to prevent him from withdrawing out of a faulty position by a secret movement.

6. These operations are most advantageous when the enemy is at a great distance from his own base. The principle may however be applied to positions less distant (two or three marches), provided the different corps have no greater distance to traverse to the point of reunion, than that which separates them from those of their own advanced posts which face the enemy. But this rule should not be understood as applying to isolated divisions upon an extended front of ninety or a hundred miles, unable to unite on a day of action, and whose movements cannot be simultaneous upon the decisive point. The difference is easily perceived between such operations and those of several corps concentrated in a position the depth of which equals the extent of front, and whose simultaneous co-operation is certain before the enemy can make an attempt upon their line.

7. By means of this system, the army, occupying a

greater space, marches more rapidly, and is enabled to subsist on the roads. Cattle and biscuit alone will be required to follow each corps, in sufficient quantity to subsist it when in the vicinity of the enemy, where the other corps having likewise arrived, they are obliged to live within a smaller periphery. The stock of provision will be sufficient if equal to the time required for collecting another.

8. Magazines are then formed in the rear as the army advances. They are collected by means of regular requisition made on the neighbouring provinces, and enforced by a few troops; contracts are entered into with the local administrations, and precautionary convoys follow from the frontiers. Cattle, rice, and biscuit are the most useful provisions; the easiest to be transported.

In this view of the theory of initial operations, such as Jomini and other authorities consider them, no great regard is paid to the waste of human life, by the frequent want or irregularity of the issue of provisions, or notice taken of the indiscipline which naturally arises when famine drives the soldier to marauding. A relentless conscription system may indeed supply recruits; but they are a very inadequate instrument when compared to formed soldiers.

It remains to examine the art of forming a plan of campaign or operations in reference to insular expeditions. In the application of masses on the base line of operations by sea or by an insular force, much difficulty occurs, especially if that base is to be obtained by force on a hostile coast; because the line of communication from the port whence an expeditionary army proceeds to the point where debarkation takes place is lengthened, uncertain, and broken. The point of debarkation becomes a secondary base; and unless a friendly fortress, or a naturally advantageous point, left unguarded by the enemy, can be occupied, the difficulties are nearly insurmountable. It is again difficult to despatch a large force in one fleet; it is dangerous to keep it together, and dangerous to allow great intervals; the elements affect the time, connection, and order of the convoy; an independent and separate service (the navy) influences the primary organization and execution; debarkation absorbs much invaluable time, particularly that of the artillery, horses, and stores. From these causes, a practice has arisen of fitting out expeditions not sufficiently formidable, with a view of ascertaining the practicability of an object, but which by that very system is often rendered impossible; for the first landing having been effected, the enemy's attention is no longer divided; he assembles his means of defence while the second convoy is expected, and the delay becomes decisive of the event. Yet if, in any military operation, the effect of masses simultaneously employed be of consequence, it is in those which commence on the sea-shore; for the troops have not only to debark and act offensively, but also to construct their means of security and retreat in case of failure. If we examine the primary operations of this class, from the wars of King William to the present period, we shall find that, with the exception of such as were favoured by chance or particular circumstances, the success or failure was dependent upon one or more of the following maxims, especially as applied to continental expeditions.

When an army is directed to make a descent upon an enemy's coast, with the object of penetrating into the country, a point of debarkation should be selected, where the enemy possesses no local means to arrest the progress, such as a fortified city or a defensible peninsula. If however circumstances compel the descent near or upon such a spot, immediate measures should be taken to mask or capture it, and secure the success of ulterior operations.

If the expedition is intended to be confined solely to the coast, the point of debarkation should possess the indispensable qualifications of facility of communication with the fleet, security of retreat and reimbarkation. A point possessed of these advantages is a fit spot for a temporary base of operations.

3. An expedition intended to operate ulteriorly should be *ab initio* superior to the probable immediate force of the enemy, so that the success of the landing and march into the country be not problematical.

4. No combinations of invasion should be made depending on the co-operation of corps expected from distant or opposite quarters. It is important to have them collected, as much as possible, on or near one point of embarkation, to proceed from thence in mass to execute the enterprise.

5. In the plan of an expedition, no combinations should be admitted which include two or more lines of operations from separate bases. Armies transported by sea are, from that circumstance, not numerous; division renders them still weaker, and if on one point a misfortune occurs, the other division must reimbark.

6. In colonial and insular expeditions, it is only necessary to combine the means in proportion to the strength of the object, and with attention to the season and climate. But on all occasions where the reduction of a fortress is in contemplation, the engineer department should possess an adequate *matériel* as well as the artillery.

All these maxims are in unison with the leading principles of the art of war, or constitute mere modifications to adapt them to maritime affairs. As examples of the importance of the first rule, may be quoted the landing of the emigrants at Quiberon: being confined to a narrow peninsula, they were immediately blocked in by the enemy. The Helder expedition, though victorious in two battles, could not penetrate beyond the neck of the Haerlemmer Meer, which makes a peninsula of North Holland. At Aboukir, again, a peninsula, similar results would have ensued, but for the circumstance that a communication could be opened on the side of Rosetta, which rendered the position central against the two exterior lines of the enemy, namely, those of Cairo and Alexandria, and enabled the British to carry their mass alternately upon each, and ultimately, with inferior numbers, to reconquer that province.

In the second maxim, the causes are pointed out which allowed the expedition to Cherbourg, in 1758, to reimbark in safety, although no regular precautions insured the measure; and those which produced the disaster at St Cast, under General Bligh, notwithstanding every precaution. The Ostend expedition had the same defects, though perhaps on this occasion the object was considered of sufficient magnitude to allow a disregard of the consequences.

Inattention to the third had a preponderating influence at the Helder. The first division, having landed, was obliged to wait behind the intrenchments of the Zyp for the arrival of the main body. Meantime the enemy, now certain of the point in danger, collected his means, and arranged the plan of defence. After three battles he was only thrown back upon stronger ground, in a position where he could neither be turned nor attacked in front with probability of success. In Egypt, the expeditionary force was likewise inferior to the enemy, and if the hostile commander had sacrificed the establishments and *Institut* at Cairo, to collect his forces on one line, he could have resisted the invasion with success. The Walcheren expedition, considered in its primary combinations and preparatory measures, was a model; as also that of the French for the invasion of Egypt. Both were wrong in the choice of the point of debarkation; but the results were different, and, from an unconquerable propensity in man, by the results they have been judged.

The expedition to the Helder again furnishes the proofs of the fourth maxim. Had the two British and the Russian divisions arrived in time to act in mass, within a few hours after the first landing, the enemy could not have matured an effectual plan of defence. But the combinations required easterly winds for the Russians and westerly for the British reinforcements, and both were nevertheless to arrive if possible simultaneously on the same spot. The Egyptian expedition was to be sustained by a corps from India and the Cape, by the Red Sea, which could scarcely by any chance arrive in proper time. At Copenhagen indeed the two divisions from Rugen (an island in the Baltic, where a British corps lay in transports) and from England did arrive without accident; but the successive divisions sent to the river Plate, to be successively defeated, are a further corroboration.

The fifth maxim is sufficiently obvious. Sir John Moore's division was off the coast of Portugal when the battle of Vimiera was fought; had it sailed conjointly with Sir Arthur Wellesley's, the result of that battle would have brought the British into Lisbon *without* a convention. If the division engaged had been defeated, a corps on board of ships could not have rendered the least assistance. In the next campaign, Sir John operated on several lines from Portugal, and Sir David Baird from a different base (Corunna), with the view of uniting at the distance of more than 200 miles on a point in possession of a formidable enemy. Such combinations produced their natural consequences; the hard pressed retreat of the army to Corunna ensued; and, as if another proof were wanting, no sooner were the troops compelled to fight a battle, than another division appeared to witness the conflict from the ships, and return to England.

To the deficiency of a proper establishment of sappers and miners, with the *matériel* required to enable the engineers to act with effect, many delays and failures may be ascribed. It has necessitated the severe system of bombardment, and repeatedly rendered the British arms odious, without thereby insuring success. Carcasses and rockets ruin the defenceless inhabitants, but have no decisive influence upon the defence of a regular fortress.

If we examine the wars in America by the rules of art, we find Lord Amherst operating by the line of Lake Champlain upon Montreal, and Wolfe by the St Lawrence upon Quebec, both successful, and yet two years without connection. Next appear isolated expeditions traversing a vast continent, deficient in numbers, and therefore always inferior to the local militias on the spot, terminating their career in defeat or capture; or else dispersed along the coast, occupied in landings for trivial purposes, and when reimbarked, leaving the enemy to boast of successful resistance. In the Canadas we behold the key of defensive operations left without a fortress. True indeed it is that a fortress does not defend a state, that an army must be looked to for that purpose; but an army is a frail instrument, and if armies defend nations, fortresses defend armies.

Reflecting on the miscarriages produced by dispersing the forces, it appears that in British military combinations it should be a maxim, never to act offensively on more than one point at a time. This rule, a fundamental principle of the Roman policy in her best days, should have been acted upon in the wars of the Spanish succession, when that question ought to have been decided in the Netherlands. The consequence of pursuing a multiplicity of offensive combinations at the same time, was never better exemplified than in the failures of the simultaneous expeditions to Buenos Ayres, Constantinople, Alexandria, and Rugen. It follows that small expeditions, hovering along hostile coasts, produce no beneficial effects. The local garrisons and militia of the country are generally superior; and a momentary debarkation produces in the mind of the enemy, not only national union, but also the ideas of victory. The debarkations at St Malo and St Cast, that under Sir James Pulteney at Corunna, most of those in America, were fraught with risks not counterbalanced by any prospects of real advantage. Those on the east of Spain were of a different character; they had a political object of importance, and served as a diversion which fixed a whole hostile army in that quarter.

It is a general rule, liable indeed to occasional exceptions, that the operations of the land forces should be confined to fixed important points, where the object is not only to land, but to conquer and maintain themselves. There is no instance in the history of the nation where a British mass of forces met with disaster, when that mass acted by itself, or with sufficient preponderance among its allies. From the nature of the sea-line of operations, expeditions, like other military enterprises, must be liable to miscarriage; but a right use of the forces will at least increase the chances of success. In the selection of the points, much must be left to the circumstances of the case, but their importance should always be in relation to the risk, expense, and time.

As these observations apply to great operations only, it is unnecessary to advert to flying corps, or such expeditions as are merely intended to alarm a coast or distract an enemy; because these, in most cases of problematical utility, should be very sparingly resorted to, and, at all events, never consist of more than a few frigates, with troops on board. The geographical extent and insular position of Great Britain afford equal facilities for defence and attack. Defence, however, when passive, is allowed to be the very worst that can be adopted in the military policy of a state; and when the national superiority at sea is considered, it becomes evident that British operations ought to be offensive. With a great number of garrisons stationed in every quarter of the world, the land forces form nowhere a considerable body; those in Britain being scarcely adequate to the local duties, and the relief of such as return from abroad. At the commencement of a war, although the militia is called out, the reinforcements required to place distant garrisons on the war-establishment absorb nearly all the infantry, and leave not only no disposable force, but even no sufficient elements to create new corps in an efficient manner. Hence three or four years of war pass in preparations on one side, and in conquests on the other. Millions are spent, and vast sacrifices made, to arrest the progress of the enemy; humiliating offers are made, which the opponent, blinded by success, has the imprudence to reject. Then, forced to still greater expense, other campaigns follow, to recover what was lost in the first. By a rational system of preparation, wars might be terminated in a short period, or altogether prevented; and yet long wars, the real cause of the prodigious national debt, are occasioned by an ill-judged prejudice against a standing army, backed by still weaker ideas of economy. Since regular armies have been maintained in Europe, the obvious utility of having at least some disposable force to give weight to negotiation, requires scarcely an argument. Instead of three battalions, the only applicable troops in 1792–3, which were sent to Willemstadt, had Great Britain possessed 25,000 disposable troops, the National Convention would have paused before it declared war, or this force would immediately have influenced the reconquest of Belgium. Even a year later, such a national force could have averted the consequences of the action of Hooghlede, the retreat from Dunkirk, and the final evacuation of the Netherlands. In the late war, the inability of Great Britain to act from the first with vigour, compelled her to fight twenty-one years, with incalculable waste of blood and treasure, merely to restore the balance of power; and the nation, which at first had only three battalions for service, ended, in 1814, with a mass of more than a million of men in arms.[1]

---

[1] According to authentic documents, this mass amounted to 1,116,813, including navy, East India, and local militia force, but exclusively of yeomanry and volunteers.

In a military point of view, the economical system has been productive of immense losses to the nation; but if, under given circumstances, in time of peace, the army must be very generally reduced, care should be taken not to destroy the elements of regeneration. On a war breaking out, all the troops in the kingdom should be brigaded, with their generals, staff, field train of artillery, commissariat, and medical officers, and concentrated as much as possible, for the purpose of rapidity of execution, and creating habits of duty in large bodies, which the staff and commissariat generally begin to learn when before the enemy, at a period when all parties should be fully acquainted with them, and when mistakes may be fatal. The orders of government are thus executed as soon as issued, and that species of confusion is obviated which all who served in the beginning of the late war must have witnessed.

Till the beginning of the present century, plans of operation were usually arranged in the cabinet, by superannuated officers, on obsolete principles, or by ministers without professional knowledge, upon combinations entirely political. The Austrian government was particularly unfortunate in this system. Plans, calculated with the precision of summer manœuvres, where every march, battalion, and detachment were prescribed, without adverting to the measures of the enemy, tied the hands of the generals, who were never successful against a formidable enemy but when they disobeyed their instructions, as Eugene did at Zenta. But when Frederick traced his own plans of campaign, although even he was not fully sensible of the laws which should regulate territorial and manœuvring lines of operations, still circumstances and superior *tact* soon led him into the true system. Jomini blames, with sagacity, some of his initial operations; but he does not sufficiently consider his circumstances and his era. He compares the operations of Napoleon, with all the resources, fortresses, population, and revolutionary excitation of France, together with the adventurous gambling of his hero, to the conduct of a sovereign who had his native throne to defend, without a military frontier, with a scanty population, a barren soil, and no pecuniary means but such as arose from his economy; and yet he rose superior to all the difficulties of his situation, though under circumstances more unpromising than those which ultimately hurled Napoleon from his throne.

II.—MANŒUVRING LINES OF OPERATIONS.

The connection between manœuvring lines and those which nature has marked out, and the views of the general-in-chief, form separate classes, each named after the nature of the connection.

1. *Simple lines of operations* are those when an army operates in a single direction from a frontier, without forming detached corps.

2. *Double and multiplied lines*, when an army acts upon the same frontier with two or three isolated corps, towards one or several objects.

3. *Interior lines of operations* are formed to oppose several hostile lines, and are so directed as to possess internal connection, and enabled to move and approach each other, without allowing the enemy to oppose a superior mass to them.

4. *Exterior lines*, on the contrary, possess the opposite qualities. They are such as an army may form at the same time upon the two extremities of one or several hostile lines.

5. *Lines upon an extended front* are those which are arranged upon a great contiguous development by isolated divisions, but still belonging to the same mass of forces, and operating upon the same object. Under this head are comprehended, likewise, lines formed by two separate corps upon one given extent. They are then double lines upon a great front.

6. *Deep or lengthened lines* are those which, commencing at their base, pass over a great extent of country before they can attain their object.

7. *Concentric lines of operations* are either several or a single line subdivided, moving from distant points in order to arrive at the same object, in front or in rear of their base.

8. *Eccentric lines* designate a single mass starting from one point, and dividing itself in order to form several diverging lines upon isolated objects.

9. *Secondary lines* are those in the great combinations of two armies, which designate their relative connection while operating upon the development of the same frontier.

10. *Accidental lines* are produced in the original plan of campaign, when unexpected events necessitate a new direction for the operations. They are of the highest importance, and rarely adopted but by generals of the first abilities.

Formerly lines of operations were considered only as they effected the *matériel* of armies: it was even advanced, that armies encamped near their magazines had no lines of operations; but an example will prove the fallacy of this opinion. Supposing two French armies encamped, one on the Upper Rhine in front of Brisac, and the other on the Lower Rhine in front of Dusseldorf, with both their magazines in the safest place, that is, behind the river. These armies must have either an offensive or defensive object, and therefore have territorial as well as manœuvring lines of operations. 1st, The territorial defensive line will extend from the point of their position to the point which they are to cover; therefore they would both be cut off if the enemy occupied that point before them. If Melas, with his army, could have subsisted near Alessandria in Lombardy after the battle of Marengo, he was no less cut off from his line of operations as long as his victorious opponents occupied the line of the Po. 2d, Their manœuvring lines would be a double against a simple one, if the enemy concentrated his masses to crush one of the armies: it would be a double external line against a double internal, if the enemy formed also two corps, but so directed that they could be united most readily.

The article in the Edinburgh Review on the work of Jomini makes the following able remarks on lines of operations. "Among all these lines, the simple and interior are the best, particularly when combined, as being most congenial to the great principle of carrying a mass of troops upon the decisive point. A few remarks will make the truth of this apparent. If an army advances from its base of operations upon one line, it is clear that the general commanding will have but two important dangers to provide against; first, that of his troops being attacked unawares; and, secondly, that of being turned and cut off from his communications with his base. The most effectual method of guarding against either is, to attack the opposing enemy first, or, as the author calls it, *prendre l'initiative;* and if, in so doing, the assailants can place themselves in such a position that a victory will give them the means of utterly destroying their adversary, while a defeat will not be of material detriment to themselves, the manœuvre must be considered as a perfect one. Now, a single and interior line has a manifest advantage over every other in aiding such an operation. An army which moves upon double, exterior, or multiplied lines, must be weakened in proportion to the number of its divisions. The general has many combinations to attend, and many dangers to guard against; his columns being on many roads, and unconnected, must also be dependent upon many persons and many orders. Obstacles will be multiplied at every step; and errors cannot be known or corrected without much loss of time. The success of his plan must depend upon the exactness and concert between the different divisions; a misfortune attending any one vitiates or destroys the whole project, and yet each column, separately, will be too weak to strike an important blow if a favourable opportunity should occur. They will suffer severely from mishaps, and they cannot well take advantage of misfortunes.

"An army that manœuvres upon simple and interior lines gets rid of all these incumbrances; the troops will be together and well in hand, with the general upon the spot, ready to rectify errors, and to superintend every movement; and upon whichever road he marches against an enemy acting upon double or multiplied lines, his combinations must be more simple, and his numbers must be superior; he will have the power of overwhelming whatever division of his adversary he may meet with, and, by thus disorganizing his opponent's plan of campaign, enable himself to cut off their communications, or to attack their columns in detail. We will suppose however that, finding their line penetrated, they might, by great exertions, unite the remainder of their scattered corps by a retrograde movement; but they will hardly be able to cover their communications, which must be nearly as numerous as their divisions, and the attacking army will give battle in the execution of a preconcerted plan, while they will be in the confusion of a baffled one. If the great principle, however, of carrying a mass upon the decisive point has governed the general who advances upon the simple line, he will, by a victory, deprive his foe of retreat, and utterly destroy him; while, if he fail, his communications are still open, and, from want of a plan, the pursuit cannot be very vigorous."

These remarks upon manœuvring lines are well illustrated in modern military history. In the seven years' war, Frederick had the choice of attacking Austria, on his left by Silesia into Moravia, in the centre through Lusatia, and on the right by Saxony, both into Bohemia. His natural territorial line was undoubtedly the first of these three; because, while his own flank was covered by the fortresses of Silesia, he could penetrate at once into the vitals of the Austrian dominions, and masking Olmutz, threaten Vienna. He did not feel the advantage of this line until the third campaign, when he was everywhere outnumbered by the enemy; and yet even then he might have had signal success, if his besieging train, &c. had been in more efficient order and better applied. From this period he became sensible of the superior utility of central lines, and from 1758 he operated successively with his principal mass in Saxony, Silesia, and Brandenburg; the same troops were victorious in all these quarters, by alternately reinforcing each corps so as to attain a superiority. Having missed the opportunity in 1757, of deciding the war by a successful invasion, he at last gloriously saved his kingdom by this new system. All these successes belong to the three first classes of simple, double, and interior lines of operations. Those of his adversaries, on the contrary, were always of the fourth and fifth exterior lines, and lines upon an extended front. For, on looking at the map of the seat of war, it will be readily observed that he operated within the triangle formed by Dresden, Breslau, and Custrin, while the enemy manœuvred outside of that figure. After the battle of Hochkirch, indeed, when this area was broken in, he made a master-stroke, by uniting his three armies in Saxony, and thus wresting from Daun the advantages of his victory. The operations of that crisis belong to the tenth or accidental lines, in which Frederick has never been surpassed. To this class belong, likewise, his invasion of Bohemia, after raising the siege of Olmutz; his march into Silesia, and manœuvres before and after the battle of Liegnitz, in 1760; and his central position at Buntzelwitz, by which he kept the enemy divided, in 1762.

The French operations in Hanover were not more successful. In 1758 they formed two lines of operations, in Hessia and on the Wezer, upon a development of 300 miles. Prince Ferdinand, manœuvring upon their extreme left, had only isolated corps to contend with, and drove them across the Rhine. Marshal Contades, after the battle of Crevelt, felt the advantage of the line of the Rhine, all the fortresses being in his hands; but while he acted without vivacity on his right, Prince Ferdinand took a central direction, and broke the concert between the two hostile armies, who, at the end of the campaign, lost nearly all they had gained, having spent their time in disjointed marches, and in writing *projets* and counter *projets*. After the battle of Bergen in 1759, the French, grown wiser, united all their forces in Hessia; they made conquests, which even the defeat of Minden did not wholly repair. In 1760, Marshal Broglie, persisting in operations in mass, made a respectable campaign; but in the next two, armies were again formed at a great distance; Prince Ferdinand again was beforehand with them everywhere. At length they approached each other to attack, but, for want of concert, were defeated at Fellinghausen.

In comparing the constant difference of the lines of operations which the Austrians, Russians, and French adopted, with those of the Prussians and Hanoverians, their opposite results are at once discovered.

During the wars of the revolution, the duke of Brunswick's march into Champagne was a simple line, but wanted corps to cover the flanks, and activity in the execution. The recovery of Belgium by the Austrians was also effected by operating in mass; but on the French frontier they wasted their time in sieges, and acted upon exterior and eccentric lines. The French operated in a similar manner, but having a line of fortresses and numerical superiority, they were at last successful, and expelled the allies from Belgium. This worthless system was then cried up, and denominated Carnot's. Accordingly, in 1795, the French persisted in acting on double lines. They manœuvred on the Rhine, by Dusseldorf and Manheim. Clerfait operating centrally, carried his masses alternately from right to left, gained the decisive victories of Manheim and the lines of Mayence, and threw the French army of the Sambre and Meuse back across the Rhine to cover the Mozelle, and Pichegru under the cannon of Landau.

In 1796, the French, in their lines of operations on the Rhine, still copying Frederick's faulty system of 1757, and their own of 1794 and 1795, were not more successful than in the preceding campaign. The armies of the Rhine, and of the Sambre and Meuse, moved from the extremities of their base to take a concentric direction on the Danube. As in 1794, they formed two exterior lines. The Archduke Charles opposed his own in an interior direction, to be more readily concentrated, and seized the critical moment, while the corps of Count Latour was covered by the Danube, to steal some marches unperceived by Moreau, and to throw his mass upon Jourdan, who was routed at Würtzburg. This decided the fortune of the campaign in Germany, and compelled Moreau's deep lines to retreat into France.

Meanwhile Napoleon commenced his extraordinary career in Italy, as Frederick had recommended half a century before. His system was to divide the enemy, and force the Austrians and Piedmontese to take two exterior lines. They fell into the snare, and he defeated them separately at Mondovi and Lodi. An army had assembled in the Tyrol to relieve Mantua; it was led on in two lines, separated by a lake (Guarda). The French general, raising the siege, hurried with the mass of his forces to meet the first column at Brescia, and routed it; the second column arrived soon after on the same ground, and was likewise driven back upon the Tyrol. Wurmser determined to cover the two lines of Roveredo and Vicenza; Napoleon, After defeating the first and driving it into the Lawis, changed his direction to the right, passed through the gorges of the Brenta, upon the left line of the enemy, and forced the wrecks of this fine army into Mantua, where it ultimately capitulated.

In 1799, the system of Carnot again prevailed. France, twice punished for operating with two exterior lines, now adopted three. An army on the left observed the Lower Rhine; one in the centre was on the Danube, and a third occupied Switzerland. These armies could not unite till they reached the valley of the Inn, eighty leagues from their base. The archduke uniting his forces in the centre, gained the victory of Stockach, and the Helvetian army was constrained to evacuate the Grisons and Eastern Switzerland. In their turn the allies committed the same fault. Instead of pursuing the conquest of this central bulwark of Europe, they formed a double line in Switzerland and on the Lower Rhine. The army in the former country was ruined at Zürich, while that in the latter was trifling about Manheim. In Italy a double line was formed by the French; one towards Naples, where 32,000 men were employed to no purpose; while the other, on the Adige, was too weak, and suffered severe loss. At length, when the army of Naples returned towards the north, it committed the fault of taking a direction from that of Moreau. Suwarow took an able central position, marched against the first of these armies, and defeated it within a few leagues of the other.

In 1800 the scene changed again. Napoleon, having returned from Egypt, displayed a new combination of the lines of operations: 150,000 men filed off on the flanks of Switzerland, opening on one side on the Danube, and on the other upon the Po. This masterly combination secured immense advantages. Modern Europe had not as yet presented such operations. The French armies, forming two interior lines, which reciprocally sustained each other, forced the Austrians to take a contrary or exterior direction, which disabled them from communicating together. By this arrangement, the reserve army cut off the communications of Melas with the base, while it preserved all its own with the army of the Rhine,[1] which constituted its secondary line. A reference to the map of that seat of war will show Moreau posted at Stockach and Zürich, and Kray facing him on the north side of the Danube; in Italy, Napoleon on the Po, at Pavia, and Tortona, with a corps at Vercelli, completely insulating Melas at Alessandria; while the French commander, in case of check, had all the gorges of Switzerland, the St Bernard, Simplon, St Gothard and Splugen open. The events of that period offer convincing proofs of the decisive effect of a proper choice of lines of operations.

In the subsequent campaign, Napoleon, breaking up from Boulogne, and directing several corps through Central Germany to approach the Danube, suddenly turned the position of Mack at Ulm, and, placing himself upon his communication, forced him to surrender. But in this campaign his fortune began to blind him. Forgetting that he had no base of operations nearer than the Rhine, he hurried forward to Vienna, and thence to meet the Russians in Moravia. Prussia was in arms, a British corps had reached the west of Germany, Bohemia had risen in mass, the Tyroleans made a successful resistance, and the Archduke Charles, after crippling the French army of Italy, had advanced to the vicinity of Vienna. At this moment, with only a small reserve at Frankfort, the Austro-Russians, who had every interest to temporize, hazarded the battle of Austerlitz; and his good fortune and the imprudence of the allies saved him from a dilemma from which that victory would not have relieved him, but for the pusillanimous feelings which signed the peace.

Similar manœuvres towards the sources of the Saale produced the disasters of the Prussians at Jena and Auerstadt. But in this war Napoleon became still more enamoured of deep and baseless lines of operations, the baneful effect of which he was not destined to feel till the campaign of 1812, when he invaded Russia without a true base nearer than the Rhine. His secondary base on the Vistula bore no relation to the depth of his line of operations, intersected by the Niemen, the Dwina, and a solitary waste of endless woods and heaths. Although he operated on a simple line, the immense distance from his base left him without communications. The extremes or pivots of the secondary base were already turned and broken, when Kutusoff moved to the rear of his flank upon Kaluga, towards the Berezina, and destroyed the greatest army recorded in modern history. The next year, though his lines were shorter, circumstances were totally altered; he operated with ability in mass; but being greatly inferior in horse, and the allies manœuvring likewise in mass, the first battles were indecisive, till his adversaries, operating upon double exterior lines,—on this occasion applicable from their great superiority in numbers and in cavalry,—moved again round the flank, and decided the question at Leipzig.

Meantime, the duke of Wellington, in the peninsula, *cunctando restituit rem.* Opposing a single line against a single line, he saved Portugal by his masterly position of Torres Vedras, without a battle. Next he drove the enemy from the frontier fortresses, by alternately carrying his masses across the Tagus. His line was shorter from north to south than that of the enemy, and he caused them to increase theirs by the destruction of the bridge of Almeras. Thus he forced his opponents to operate exteriorly. After the victory of Salamanca, his march into Spain was by two interior lines; and though this operation has been blamed, because it ended in a retreat, we forget that the enemy was obliged to abandon the south, or one half of Spain, to produce it. The next operation was upon a single and decisive line. The enemy was encountered at Vittoria before he could concentrate his forces, cut off from his base, and driven headlong into Pampeluna.

Advantageous and disadvantageous lines.

This comparison of the combinations and results of the most celebrated campaigns shows, that all the lines of operations that have been crowned with success depended on general principles, of which the following are the principal heads.

1. A double line of operations is advantageous if the enemy has likewise a double line, provided theirs be exterior, and at a greater distance than yours, and unable to unite without first risking a battle.

2. An army possessing interior lines more connected than those of the enemy, can, by strategical movements, destroy them successively, by carrying the mass of forces alternately upon each point; as was exemplified in the campaign of 1758, and subsequently at Manheim and the lines of Mayence, at Würtzburg and Emmendingen, at Lonato and Castiglione, Trente and Bassano, at Stockach and Zürich, Abendsberg and Eckmuhl, &c.

3. In order to effect this movement, a corps should be left before the army which it is intended to keep in check, with orders not to engage, but merely to retard the march, by taking posts behind defiles or rivers, and retreating towards the army.

4. From the above premises, it follows that a double line of operations against an enemy whose corps are in closer connection, will always be unfortunate with equal numbers, if the enemy profits by the advantages of his situation, and manœuvres with rapidity within it.

---

[1] Army of the Rhine, of the Sambre and Meuse, were names given to French armies, although they were not always on these rivers.

5. A double line of operations becomes still more dangerous when its parts are separated by several days' march.

6. Simple and interior lines, on the contrary, are always most safe; because they admit the action of the mass of forces against the isolated divisions of the enemy, if he be so imprudent as to venture an action.

7. A double line of operations, however, may be adopted with success, if the forces employed are so much greater, that superior masses can be presented to the opponents on both its parts.

8. Two anterior lines, mutually sustaining each other, and facing two exterior lines at a certain distance, must avoid being compressed into a small area; for the exterior hostile lines might thereby act simultaneously.

9. Again, they should not operate at too great intervals; for the enemy might have time to crush one of these divisions, while it is weakened by detaching to the other, and thus gain a decisive advantage.

10. It being the interest of a commander to divide and isolate the opponent's forces, his manœuvring lines should never have the object of drawing the whole hostile forces upon him; as Tempelhoff boasts Frederick to have done in the campaign of 1760.

By reference to the preceding sketch of the operations in late wars, the value of these rules is everywhere observable. When the details in history are examined, such as they are presented by authors acquainted with the art of war, they form a key, which opens an unerring way into all the causes of success and misfortune. Thus, in what has been said on accidental lines of operation, it might have been added, that Napoleon did not know how to avail himself of them, when he was advised to operate by the right bank of the Elbe, and change his direction upon the pivot of Magdeburg, instead of risking the battle of Leipzig, and suffering, in violation of the eighth rule, the enemy to place him between two fires; nor in Champagne in 1814, when he operated at too great a distance, overlooking the ninth rule, which gave the allies time to force the gates of Paris, thus employing the just system of throwing the mass of their forces upon the most important point. The duke of Wellington's defensive campaign in Portugal hinged upon a prudent application of the second rule; and Napoleon, in 1814, could not have resisted so long as he did in France, but by the same system. Although the allies at that moment conducted their operations on the seventh rule, perfectly applicable under the then existing circumstances, yet the vast superiority of internal lines remained evident. But when his eccentric movement placed him out of the sphere of real operations, the allies applied the third rule with perfect success, and effected his fall.

In order to complete the view of territorial and manœuvring lines, it is requisite to consider them as they are affected by the configuration of frontiers.

1. In order to operate with advantage, there should not be two different armies upon the same frontier; because,

2. Double lines will always fail, with equal chances, against a single line, as has already been shown.

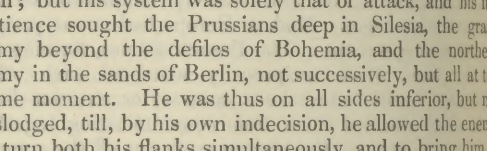
3. Interior lines resist with advantage against exterior lines, either upon the same or upon two different frontiers. The objection that Pichegru proved successful in 1794 is not valid; because Prince Coburg did not avail himself of his interior line, but acted by detachments, while he remained inactive with his mass, inferior in strength, and unsupported by fortresses on the flanks.

4. When the hostile fortresses are scattered upon a line of great extent, the most advantageous manœuvring line is upon their centre; as the Russians experienced to their cost in the beginning of the campaign of 1812: but on all other occasions, the best direction is upon one of the extremities, and from thence on the rear; as exemplified in 1800 in Italy, in 1805 in Bavaria, and the next year at the sources of the Maine and Saale, &c. When central masses are moved with ability against scattered corps, all other things being equal, they must always be successful, often even without a battle; as when Moreau, making demonstrations against the left of Kray, near Huningen, moved rapidly into Switzerland, whereby the greater part of Swabia fell into his hands without an action. The march of the duke of Wellington upon Madrid and Burgos produced the immediate evacuation of the south of Spain; and the movement of Kutusoff upon Kaluga forced the French from Moscow and out of Russia.

5. The configuration of a frontier may have important influence on the direction of lines of operation. Central positions, forming salient angles towards the enemy, such as Bohemia forms towards Prussia, Switzerland towards Austria or Saxony, as it was circumstanced in 1813, are the most advantageous; because they are naturally interior, and lead to the flanks and rear of the opponent's defensive line. The sides of these salient angles are therefore so important, that all the resources of art should be added to those of nature to render them impregnable. Switzerland and Bohemia are sufficiently proved to possess these natural advantages; but Saxony appears more doubtful, because Napoleon was at length defeated at Leipzig. Yet it was his conviction of these central advantages that made him neglect to change the line of his operations upon the pivot of Magdeburg; and if we examine the character of the operations, though the allies were numerically, and especially in excellent cavalry, superior, we discover that when his defensive manœuvres were confined to a moderate distance from the Elbe, and the ridge of the mountains of Bohemia, no impression could be made upon him; but his system was solely that of attack, and his impatience sought the Prussians deep in Silesia, the grand army beyond the defiles of Bohemia, and the northern army in the sands of Berlin, not successively, but all at the same moment. He was thus on all sides inferior, but not dislodged, till, by his own indecision, he allowed the enemy to turn both his flanks simultaneously, and to bring him to action between two fires at Leipzig. We may take occasion to revert once more to the double exterior lines of the allies here, and in 1814 in Champagne. When each of the armies operating exteriorly amounts to 120,000 or 150,000 men, they possess a consistency which obviates all need of co-operation; for, admitting the enemy to be even stronger, there is not a great disparity of force between the parties, which can be deployed and brought into action on the same field of battle: hence the weaker army can decline a battle, and in both these cases, where the allies had great superiority of cavalry, they could begin and break off a battle at their pleasure; as they proved at the first battle of Leipzig or Lützen, and at Bautzen.

6. Where no such central position or territorial projection exists, the same effect may be produced by the relative direction of the manœuvring lines, as exemplified in fig. 1. CD, manœuvring on the right flank of the army AB, and HI moving upon the left flank of FG, form two interior lines, CK and IK, upon the extremities of each of the exterior lines AB and FG, both of which may be destroyed by carrying the mass of forces alternately upon them. This combination presents the effect of the French campaigns of 1800 and 1809. It is also the spirit of the duke of Wellington's defence of Portugal; for, by his

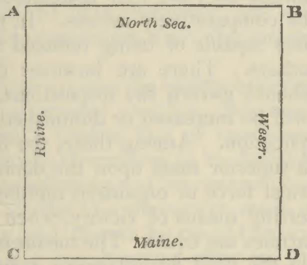
Fig. 1.



ridge on the Tagus, he had a direct and interior communication on both his lines north and south of the river, while the enemy, being placed on the segment of a circle, had only the precarious connection by the bridge of Alme[illegible]s, which being destroyed, he could not advance from either Andalusia or Salamanca, without immediately placing himself in the disadvantageous position here described.

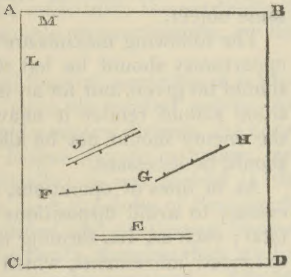
7. The configuration of the theatre of war may possess the same importance as that of a frontier; for, in fact, every theatre of war may be considered as a quadrilateral figure. To elucidate this idea, the scene of operations of the French army from 1757 to 1762, and the operations of Napoleon in 1806, may be cited. In fig. 2, the side AB being enclosed by the North Sea, the side BD by the river Weser, base of the army of Prince Ferdinand; CD representing the river Maine, base of the French, and AC the Rhine, likewise in possession of the French; their armies operating offensively on the sides AC and CD, had the third AB the North Sea in their favour, and therefore BD was the only side which they were to gain by their manœuvres to have possession of the four sides, and consequently of the base of all the communications of their adversary.

Fig. 2.



This is more clearly exemplified in fig. 3. The French army E, proceeding from the base CD, to gain the position FGH, cuts off the allied army J from the side BD, its only communication and base. It would thus be driven into the angle LAM which is formed near Embden by the line of the Rhine, the Ems, and the sea; while the army E could always communicate with CD or the Maine.

Fig. 3.

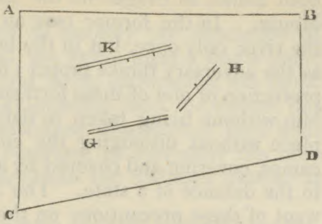


The manœuvre of Napoleon on the Saale, in 1806, was combined on the same principles. He moved upon Jena and Naumburg in the position FGH; and then advancing by Halle and Dessau, he threw the Prussian army J upon the side AB, formed by the sea. The fate which attended that army at Erfurth, Magdeburg, Lübeck, and Prentzlow, is well known. The great art therefore consists in combining the marches so as to arrive upon the communications of the enemy without sacrificing one's own. Now the lines FGH, by means of the prolonged position, and the angle formed towards the extremity of the enemy, always preserves the communication with the base CD. This constitutes the application of the manœuvres of Marengo and Jena.

When the theatre of hostilities is not near the sea, it will be still circumscribed by some great neutral power, which guards the frontier, and encloses one side of the quadrangle. No doubt this barrier is inferior to the sea, but, in a general view, it must nevertheless be considered as an obstacle, upon which it is dangerous to be driven after a defeat, and advantageous to push an enemy. A state with 200,000 men will not suffer its neutrality to be violated with impunity; and if a beaten army ventured so to do, still it would be cut off from its base. But if an inferior power forms the limit of the theatre of war, the square of operations may then be considered as extending over it to the next great neutral power, or the sea.

To give a still more convincing proof of the justness of the preceding ideas, let us examine the scene of the campaign of 1806-7 in Poland. The Baltic and the frontier of Austrian Gallicia formed the two sides AB and CD of the above square. It was of great consequence to both parties to avoid being driven upon either of these obstacles. The configuration of the frontiers may modify the sides of the square, and convert them into a parallelogram, or a trapesius, as in fig. 4.

Fig. 4.



In this case, the army GH, being in possession of the sides AC and CD, would be still more favourably situated, because the base of the opponent being contracted at BD, would be more difficult to keep open. The front of the base BD having less extent, offers fewer resources for manœuvring, and affords to the army GH the means of operating with more success; because the direction of the line CD naturally leads upon the communications of the enemy, and because the space to be occupied in order to cut him off is shorter, and therefore more easily held with concentrated forces.

The theatre of war in Prussia and Poland, previously mentioned, was precisely of this figure. The frontiers of Austrian Gallicia, extending to the Narew, formed, by the line of the Vistula, the contracted side BD; and the manner in which Napoleon embraced that line at Pultusk and Eylau was similar to the figure here shown. This operation had however its unfavourable chances; the first depending upon the doubtful trust to be reposed in the neutrality of Austria, and the second upon the great distance from the base of operations, which exposed the communications of the armies with the Oder to the mercy of the cabinet of Vienna. It depended even then upon Austria (as indeed it had the year before depended on Prussia) to put a stop to these endless invasions. The manœuvre of the French general was good, but the operation of the statesman was only daring. These examples are sufficient to demonstrate that the manner of embracing a theatre of war is amenable to the two following principles.

1. To direct the masses upon the decisive points of the line of operations, that is, upon the centre if the enemy has been so imprudent as to scatter his forces, or upon an extremity if he is in a contiguous line.

2. To make the great effort in the latter case upon that extremity which has its back against an insurmountable obstacle, or which leads upon the communications of the enemy without sacrificing our own.

Defensive operations.

Defensive operations, in a great measure already examined in the preceding discussions, require, nevertheless, some further remarks. Passive defence offers no security to a state, nor fortresses without an army; it is confiding in a shield without a sword. Reason and experience alike prove that defensive system to be the best, which embraces the greatest number of offensive facilities; for these we refer, in particular, to interior and simple lines, and those directions of lines which best anticipate or counteract the most effectual offensive ones. But as defensive measures imply inferiority of forces, they must in a considerable degree depend upon local means to counterbalance the superiority of the enemy. Rivers and chains of mountains are the natural obstacles; fortresses, intrenched camps, and well selected positions upon the most advantageous lines of defence, the artificial means in a territorial front. Fortresses, with *têtes de pont* upon a river parallel to the frontier, are very advantageous; but upon a river perpendicular to the frontier they are still more useful, particularly if fortified upon both banks, as Prague on the Mulda, or Maestricht on the Meuse. In the former case an offensive army must cross the river only once, but in the latter it must cross as often as the adversary thinks proper; for, placing his camp under protection of one of these fortresses, the enemy cannot pass him without being taken in flank or rear, nor besiege the place without dislodging the enemy. Hence intrenched camps, covering and covered by a fortress, add considerably to the defence of a state. The Austrians felt severely the want of these precautions on the Danube in the late wars. Thus the operation of Mack upon Ulm would have been good had he moved in time to attack from thence either on the right or left of the river; but to have rendered it secure, there should have been fortified positions on the Schellenberg at Donauwerth, Ingolstadt, and Ratisbon: for then he could always place the river between him and the enemy; and if the latter operated on both banks, he could attack with his whole mass that part which was most convenient, before the other could cross to assist it. Fortifications are also eminently useful in the defence of passes in chains of mountains. The insignificant fort of Bard, with 600 men, arrested the progress of the principal column of Napoleon, when descending the Great St Bernard into the valley of Aoste in 1800; and if the fort had been better secured, the whole plan of campaign would have failed, for Melas would have had time to arrive and defeat the enemy in detail. Again, the French emperor having constructed the fine roads into Italy, neglected to secure them by any fortifications, and the first military use that was made of them was by the Austrians in the two successful invasions of France, where the old fort of L'Ecluse, near Geneva, was the only point that could, and actually did, retard them some days.

Fortresses likewise secure the magazines, stores, and hospitals of an army, and save the *matériel* and broken troops after a defeat. Pampeluna saved what did escape of the French after the battle of Vittoria, as Prague did the Austrians in 1757. But in order to make them capable of producing the share of security to a state which reason can expect from them, fortresses should not be too numerous, because they absorb too great a proportion of troops for garrisons, and cost immense sums; nor small, for then they are easily embraced and overpowered by artillery; nor all on the frontiers, for if the enemy penetrate beyond them, the great arsenals, depots, founderies, &c. of the nation are no longer within reach of the defensive army, which is also deprived of the *appui* for a position to cover the capital, and turn the flank of the invader. In the last campaigns, France felt the want of intermediate fortresses. If such had existed about Soissons, on the Marne, and about the junction of the Seine and Aube, the avenues to Paris would have been more easily defended. Intrenched positions are often eminently useful, provided they intersect or flank the most direct lines of operations; but as they do not contain arsenals, &c. they are less so than fortresses, and the selection of their site is extremely difficult. Those of the Russians at Drissa, upon the line of Moscow, were abandoned. The intrenchments of the French on the frontiers of Spain and at Toulouse were forced; but those on the Isla near Cadiz, and at Torres Vedras, both saved kingdoms. A position ably chosen has sometimes the same effect. That of Dumouriez, near the wood of Argonne, arrested the advance of the duke of Brunswick in 1792; and that of Kutusoff at Malojaroslaf, near Tula, forced the French to retire by the road they came. Both were on the flank, and menaced the rear of the enemy. Dumouriez, in the north-east corner of the French frontier, presented a salient angle upon a simple line of operations towards the German and the Netherland fronts of defence, and was near the fortresses of Lorraine. Napoleon, in 1814, endeavoured to recover a similar line after the battle of Brienne; but it was then beyond the sphere of operations, and his march occasioned him the loss of his empire. To conclude, defensive war does not consist in covering every part of a state, but in preventing an enemy from obtaining any advantage which may enable him to accomplish his main object.

III.—BATTLES.

Between a battle won and a battle lost there is an immense distance, said Napoleon, the day before the conflict at Leipzig—empires lie between them; and indeed the plan of campaign, and the strategical movements, are only so many preparatory dispositions to arrive at the great crisis of a battle. The rules applicable to battles, therefore, form the most important branch of the science of war; because, unless they are well understood, all other knowledge will be comparatively useless. In many respects this branch is less capable of being reduced to fixed principles than the others. There are however certain general rules which should govern the dispositions, and the chance of success will be increased or diminished in the ratio of their due application. Among these, the first is that of operating with a superior mass upon the decisive point, because the physical force of organized numbers in arms furnishes the unerring means of victory, when the moral qualities in both armies are equal. The means of bringing this force to bear in the most advantageous manner is the art of fighting; consequently, courage and fortune being nearly balanced, that general who can operate with the largest mass upon the most decisive point must be successful. But to effect this purpose, the combinations must be such as to produce a unity of movements, conducing simultaneously to the same object.

The following maxims are of general application: 1. No opportunity should be left till the morrow. 2. No battle should be given, but for an important object, unless the position should render it unavoidable. 3. After a victory, the enemy should not be allowed to recover—the pursuit should be incessant.

As in lines of operations, so on fields of battle, it is necessary to avoid dispositions which have generally proved fatal; such as, 1st, forming isolated divisions; 2d, ordering extended movements, which deprive the army of a part of its strength, and enable the enemy to ruin either the main body or the detachment; 3d, positions with too great an extent of front; 4th, allowing obstacles to separate the wings, or obstacles which prevent the connection of columns, and expose them to separate defeats.

The finest combinations are those which produce an oblique order of battle, those with a wing reinforced, those which out-flank the enemy, and those which form a perpendicular upon a hostile extremity, or upon a scattered centre. These are almost always successful, because they present a whole line to an extremity, and therefore a greater mass than the enemy. Thus the fundamental principle of all military combinations, namely, to effect with the greatest mass of forces a combined attack upon the decisive point, is applied; and it is easy to understand how a general of ability, with 60,000 men, may be able to defeat 100,000, if he can bring 50,000 into action upon a single part of his enemy's line; for battles are decided, not by troops upon the muster-rolls, nor even by those present, but by those alone who are simultaneously engaged. Numerical superiority of troops not engaged, so far from being useful, only increases the disorder, as was fully exemplified at Leuthen.

There is not a great variety of measures applicable to this maxim.

I. The first is evidently that of taking the lead in the movements. The general who is enabled to have this advantage, can employ his forces wherever he thinks them applicable; while, on the contrary, he who is obliged to await the enemy, is no longer master of a single combination, because his movements must be subordinate to those of his adversary, and it is too late to arrest them when they are already executing. The general who takes the lead knows what he intends to perform; he conceals his march, surprises or overpowers an extremity or a weak part of the hostile line, while the waiting army is defeated on one of its points, before the knowledge of the attack has reached its commander. Hence the following are corollaries.

1. An army taking the lead in a movement can conceal it until in full execution; therefore, when the manœuvre takes place in the interior of its own line of operations, the commander may gain several marches of the enemy.

2. To judge soundly of military operations, it is highly important to banish all calculations which suppose that the hostile general will be informed of a movement, and will oppose it by the best possible manœuvre, from the instant that the movement is begun.

3. When two armies combine to place the enemy between two fires, from the distance of several marches, they must group the disposition upon a double line of operations against a simple one, and expose themselves to be defeated separately if the enemy takes advantage of his central position. Such a manœuvre is similar to a movement made at a distance against the flanks, and should be ranged among those which cannot produce a simultaneous effect at the moment required.

II. The second consists in directing the movements against a weak point of the enemy, when that point offers the greatest advantages.

An attack to the front is always to be avoided, if a concentrated effort can possibly be made upon the extremity of an enemy's line, for which simple demonstrations on the front are sufficient.

Against double and scattered lines of operations, it is preferable to direct the attacks upon the central points; for the mass of forces having ruined a central division, the corps to the right and left can no longer operate in unison, and are forced to retreat eccentrically; as was proved in the disasters of Wurmser, Mack, and the duke of Brunswick. Against simple lines of operations, and contiguous lines of battle, the weak points are the flanks, because they are liable to be crushed before they can be sustained. Albuera offers perhaps the only positive example to the contrary in modern history; for here the right wing of the allies was turned and routed, and yet the battle gained by the centre forming an echellon to the rear.

A deep column being attacked on the head, is in a similar condition as an extremity of a line; both the one and the other are engaged in succession and defeated, or what is termed rolled up. This was proved at Rosbach and Auerstadt. It is however more practicable to make a fresh disposition from a column than with the extremity of a line, when attacked by the enemy.

In executing a general strategical movement against an extremity of an enemy's line of operations, or of position, a mass is not only brought to bear against a weak point, but also from that extremity, it becomes easy to gain the rear and communications, either of the base or of the secondary line of the opponent. Napoleon's manœuvre in 1805, by Donauwerth and the line of the Lech, turned the line of communication of Mack with Vienna, which was his base; and it intercepted his connection with Bohemia, which was his most important secondary line, by which he expected the assistance of the Russians. Such were also the views of Soult when he turned the allies at Albuera, and of Junot in his attack upon the flank and rear of the British at Vimiera. Napoleon performed the same manœuvre against the Prussians in 1806 by Saalfield and Gera. Kutusoff in 1812 by Kaluga and Krasnoi, the grand allied army in 1813 when it debouched from Bohemia upon Dresden and Leipzig, and Napoleon finally attempted it in 1815 by Wavre.

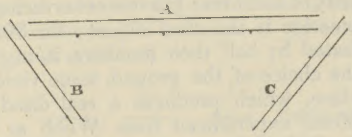
1. But if it be intended to remedy the deficiency of numbers, by acting with all the forces upon a single point of the enemy's line, that line being contiguous, the point selected should be as far as possible from the centre, because the centre can be sustained immediately from both the wings; while, on the contrary, an extremity can only receive succours by degrees from the divisions nearest at hand.

2. An attack upon the centre is never advisable excepting when the hostile line is very extensive, and scattered into separate divisions: then indeed the result must be successful from the same causes, and the consequences even more brilliant, because the enemy's corps will thereby be totally separated, and disabled from re-uniting; whereas an attack upon the flank can produce similar success only under particular circumstances.

III. The result of the preceding truths leads to the maxim, that as it is better to attack the extremity of a line, yet that both the extremities should not be attacked at the same time, unless there be a very great superiority on the part of the assailant. An army of 60,000 men forming two corps of 30,000 each, for the purpose of attacking an enemy equally numerous, is deprived of the power of striking a decisive blow; because it enables the adversary to take equal measures, or even, if the movement be extended and unconnected, to assemble his mass against one of the divisions, and destroy it by his momentary superiority. Multiplied attacks by means of a greater number of columns are still more dangerous, more repugnant to the best principles of war, particularly when they cannot commence acting at the same moment and upon the same point. But when there is a very great superiority of force on the side of the assailant, then indeed both the extremities of the hostile line should be attacked, because thus a greater number of troops is brought into action on both his wings; whereas if this great superiority were kept in one mass upon a single point, the adversary might deploy as many as the other party could bring into action, and thus engage with equal numbers. In this case it is only requisite to collect the greatest mass upon that wing where the greatest success is expected. Daun manœuvred in this way at Hochkirch, and the whole allied forces at Leipzig.

To illustrate this maxim more fully, it is necessary to enter into some detail, and fix a few particular principles. If 50,000 men, intending to attack 60,000, should form two corps of nearly equal force, and, with a view to embrace both the extremities of their line, should extend and isolate the attacks, it is clear that the 60,000 will have the facility of moving more rapidly within the interior of their line, than the assailant's corps with such a mass between them, as fig. 5 demonstrates. The two corps B and C might gain momentarily some ground, but the enemy A, leaving a corps to check C upon the most advantageous ground for defence which its position might offer, could throw the remaining mass of forces on the front, flank, and rear of B, which must consequently be destroyed. If B and C should have a third detachment on the centre, the result would be still more disastrous, for then separate corps would attack without union a force everywhere imposing, which could not fail to overpower them. This took place at Kollin, from inattention to the orders of the king; at Neerwinden in 1793; and at Stockach in 1799, where Dumouriez and Jourdan were defeated by Prince Coburg and the Archduke Charles. At Krevelt

Fig. 5.



a similar result would have occurred if the French army had been ably commanded, and exercised in great manœuvres. At Blenheim, all Eugene's efforts were unavailing, even when he had gained the flank, until Marlborough's success decided the victory.

The truth of these observations is so manifest, that it may be applied to an army superior in numbers: 50,000 attacking in this manner an army of 40,000, would still incur all the same risks; and if the inferior force, after leaving a corps to mask one attack, should take a rapid offensive measure, and overtake the enemy in his preparatory dispositions, which would necessarily be calculated upon the principle of finding the opponent in his position, the heads of his columns might be turned and completely routed. But if the two hostile attacks should have between them some difficult object, a wood or river, they might each in their turn be destroyed. Examples of this kind occurred at Lonato, Castiglione, Abendsberg, Eckmuhl, and Ratisbon.

When however the attacking army is double the force of the enemy, the principle no longer holds as stated in the cases of Hochkirch and Leipzig; but, to avoid the danger of divided forces, it is requisite to have the lead, and to conceal it in such a manner that both attacks may commence nearly at the same moment. Thus two maxims, in appearance contradictory, are derived from the same principle.

1. An army intending to attack another of equal or superior force cannot insure success but by a concentrated effort upon a single point of a weakened line, which is not in a condition to be timely supported.

2. But when a superior army attacks one much weaker, two or three divisions should be formed, in order to bring all its masses into action against the inferior masses opposed; for if the attack were confined to a single point, the whole of the forces could not be brought into line, and the enemy might deploy an equal number; but it is necessary that the whole combinations centre on the same ground, and at the same instant, to produce unity of execution, and avoid partial and successive defeat.

3. As every front of operations and each position of battle contains a decisive point, it is important that the repartition of forces insure not only a general superiority over the enemy, but also that a strong reserve be appropriated to support the attack upon that principal point.

These maxims are more especially applicable to battles than to strategical operations; for with these no necessity demands that corps acting at the distance of several marches from each other should engage exactly at the same hour, and it would be impossible to do so on the same ground. But if the principle is to be enforced differently, it is still of full efficacy. It may appear that in these ideas the main stress of the argument rests upon the local superiority of numbers; but it is nevertheless true, that their combination is the chief object; for 30,000 men may be defeated by half their numbers, if, in the disposition and in the choice of the ground, some vicious arrangement take place, which produces a real disadvantage; such as La Motte experienced from Webb at Wynendael, Chevert from Imhoff at Meer, and the Austrians from Moreau in the defiles of Hohenlinden.

IV. In the strategical movement of a great mass in a combined effort upon one point, it is advisable to keep the forces concentrated within a space approaching to square, so as to have them perfectly disposable; or, in other words, that the depth of the disposition be nearly equal to the front, enabling the battalions to arrive with promptitude from all quarters towards the point attacked. Extensive fronts militate as much against good principles, as great detachments and isolated divisions deprived of the means of being sustained. The inattention of Napoleon and Ney to this maxim gave Benningsen the advantage at Eylau; and the care of the allies in 1815, notwithstanding the difficulty of guarding an open frontier, enabled them to concentrate their masses at Waterloo.

V. One of the most efficacious means of applying the above general principles, is to induce the enemy to take contrary measures. By means of small corps of light troops, jealousies may be created for some important points of his communications. If he can be persuaded that they are formidable, he will be tempted to detach strong divisions against them, and, scattering his forces, be disabled from acting with vigour himself, and be exposed to an attack from superior forces. Operations by detachments have nevertheless been in fashion. To divide and subdivide, till the main army was reduced to the secondary character of mere observing, was considered as the very summit of strategical science. In the Hanoverian campaigns, the French, with two great armies, acted upon this system; nor could they ever be undeceived, although Prince Ferdinand, with less than half their force, contrived not only to reconquer the country, but afterwards to keep them constantly at bay, and even to attack them with superior numbers. The Austrians, and the army of the empire, operated similarly in Saxony, and reaped similar fruits. But Mack, trained in the Turkish wars, was the great patron of cordons and scattered posts, with inert positions to sustain them. The Austrians have however little reason to exult in the success of their system. The least mischief which they have derived from it was, that they fought on accessory points, while the main armies, reduced in strength, were unable to do more than menace the principal objects of the campaign, wasting their time until they were attacked by superior forces.

Nor are hostile armies destroyed by merely taking positions upon their communications, and remaining inactive within them. Had Napoleon halted upon the Lech in 1805, or on the Saale in 1806, he could neither have prevented the escape of Mack by Donauwerth, nor the retreat of the duke of Brunswick to the Elbe. The art of war does not consist in incursions upon communications, but in placing the mass upon them, in order to attack the enemy with decided advantage. Detachments upon the communications of the adversary are only accessories of secondary utility.

VI. When the lead is taken in a decisive movement against the enemy, great importance is attached to an exact knowledge of the positions and movements which he may undertake. Spies are then of the utmost consequence, but partisans, thoroughly versed in watching the enemy, are of still greater utility. For this purpose the general should scatter small parties in all directions, and multiply them with as much care as he would show to restrain them in great operations. Some divisions of light cavalry, expressly organized for this service, and not included in the order of battle, are the most efficient. To operate without such precautions is to walk in the dark, and to be exposed to the disastrous consequences which may be produced by a secret march of the enemy. Generally speaking, these measures are too much neglected. The *espionnage* is not sufficiently organized beforehand; and the officers of light troops have not always the requisite experience to conduct their detachments.

The Cossacks under Platoff, Chernicheff, Tettenborn, &c. in Russia and Poland; these, with the Prussians under Lutzow, in Germany and France; and the Guerillas of Mina, the Empecinado, and others, in Spain and Portugal, have shown the immense advantages to be derived from such services. While they were few in number, their real importance was not fully understood; but when 15,000 or 20,000 of them appeared in the field, especially in a friendly country, they became the most formidable enemy, with respect to the combinations, which a general could encounter, because those were always liable to be disjointed by the uncertainty of the timely arrival of orders. Every convoy demanded a numerous and well-conducted escort, and every march was endangered by the want of real information relative to the hostile positions. The duties, greatly multiplied, exhausted a great part of the army; and the irregular cavalry was soon rendered unserviceable by their excessive fatigue.

VI. It is not sufficient for a good operation of war to convey with ability the mass of forces upon the most important points; they require moreover to be brought into action. If they remain inactive when arrived upon those points, the principle is forgotten, for the enemy may make counter-movements to defeat the project; and it is therefore indispensable that, from the moment his communications or his flank are gained, the mass of forces must march up to him and attack. This is the moment when a simultaneous employment of the troops must take place. Masses of troops present do not decide battles, but the acting masses alone have effect; the former indeed produce that consequence in strategical movements, but the latter determine the success of the action.

To insure this result, a general of ability will seize the proper moment to force the decisive point of the field of battle, and combine the attack in such a manner that all his forces will be brought into action, with the exception always of the reserve. But if the efforts emanating from this principle fail of the desired success, no other combination remains than a simultaneous general onset, in which the reserve is to be brought forward, to make a last and decisive effort.

VII. We now come to battles proper, all the combinations of which are reducible to three systems.

The first includes defensive battles, where the enemy is expected in a strong position, with the simple object of maintaining the ground. Such were the positions of Tallard at Blenheim, Villeroy at Ramillies, Marsin at Turin, Daun at Torgau; and the events are sufficient to show their general disadvantage.

The second is the opposite system, wholly offensive. It consists in manœuvres of attack wherever the enemy may be found, such as those of Marlborough at Blenheim, Ramillies, and Oudenarde; Frederick at Leuthen, Zorndorff, and Torgau; Napoleon at Jena and Ratisbon; Wellington at Vittoria, and the allies at Leipzig.

The third offers, in some measure, the middle term between the other two. It consists in selecting a field of battle, carefully reconnoitred beforehand in its strategical capabilities and advantages of ground; then to wait the enemy's attack, and to fix upon the proper moment of passing from the defensive into offensive measures with the best chances of success. In this class must be reckoned the combinations of Napoleon at Rivoli and Austerlitz, of Blucher at the Katsbach and Laon, and of Wellington at Salamanca and Waterloo.

It is difficult to prescribe fixed rules by which the choice of any of these systems should be guided. The circumstances of the moment, the moral character of the troops, considered as affecting their courage, discipline, and inclination, their national temper, and the conformation of the ground, must be taken into account.

1. Under these general considerations, it may be fixed, that the best mode is to act offensively on all occasions, when the troops are inured to war, and the ground presents no extraordinary features.

2. Where the locality of the field of battle is difficult of access, either from natural or artificial causes, and the troops of different nations not having the same unity of feeling and of discipline, it will be preferable to receive the attack in a position previously selected, with the determination of assuming the offensive when the enemy shall be exhausted by the first efforts.

3. When the strategical circumstances of the parties are such, that one is obliged to attack the other without considering localities; as, for instance, to prevent the junction of two hostile armies, or to crush an isolated corps, &c.

4. When particular circumstances, as the extreme inferiority of numbers, forbid any other than strictly defensive measures; such as Eugene took at Chiari, Abercromby on the Zyp, and Moore at Corunna.

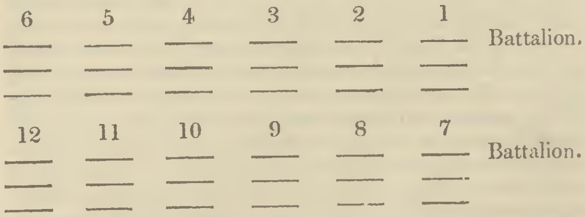
Battles in general, whether offensive or defensive, notwithstanding all the varieties of ground and changes of position, may be classed into three systems of disposition, or what are termed *orders*, each subject to some modifications.

First, the simple parallel order, or that in which hostile armies are drawn up in parallel lines, to advance or receive the attack. Jomini justly observes, that accident or superior valour alone decides the contest in this class of orders, and that the soldier is entitled to all the credit; because such a disposition being the fruit of ignorance and incapacity, the general can have no part in it. Notwithstanding this censure, it is somewhat singular that the only battle in which a considerable British corps was severely handled was of this description, when Berwick defeated Lord Galway at Almanza. Accident, it must be owned, had a great share in this battle; for it is asserted that the statue of St Antonio, the nominal commander-in-chief, was shattered by a cannon ball, which instantly caused the Portuguese to retreat, and leave the British and Dutch to their fate.

The second order is the parallel, reinforced upon one or several parts of the line. In this class, especially if dispositions with an angle to the front or rear are included, most of the great victories of ancient and modern times may be reckoned. For although it is not the most perfect in theory, it is the most constantly applicable in practice, under almost every possible character of ground, or counter-disposition of the enemy.

The oblique order of battle is the third and the best class of tactical dispositions; but in the application, great simplicity of combination is necessary, and great prudence in the execution. Against a manœuvring army ably commanded, it will always be very difficult to apply it; but when produced, the effect is instantaneous and decisive: it is the triumph of discipline and of grand manœuvre.

IX. Orders of battle, or the most appropriate disposition for leading troops into action, should possess the inherent qualities of mobility and solidity. To attain these two objects, troops which are to remain on the defensive should be partly deployed and partly in columns, as the allied army was at Waterloo, or the Russians at Eylau; but the corps destined to attack a decisive point should be disposed into two lines of battalions, formed into columns of more or less density. Jomini proposes columns of grand divisions (according to the French formation of a battalion of six companies, making three grand divisions).



Three grand divisions would thus form three lines, and the second line three more. This order, according to his view, offers much more solidity than a deployed line, which waves too much, retards the impulse necessary for attack, and prevents the officers from managing their men. In order to facilitate the march, obviate the great density of the mass, and procure a greater front, the divisions should be formed only two deep; for thus the battalions will be more moveable. The march in front, three deep, is always fatiguing to the centre rank, which, being pressed between the first and third, produces fluctuation, and consequent faintness in the onset. In this manner all the desired strength will be produced; the three grand divisions giving a depth of six ranks, which is more than sufficient; and the front being one third longer, augments the quantity of fire, if it should become necessary to use it. The enemy likewise will be awed by a display of greater numbers, and the artillery will have less effect than upon more solid masses.

If the proposal of Jomini were applied to the British system of battalion, the same effect would be obtained by fronts of wings of battalion, each three deep. What is said of fluctuation in the march is indeed true; but the lock-step is never, and cannot be, observed, in a charge or rapid advance to the front in action. The ranks open in those cases sufficiently to allow freedom of step. Firing three deep, though practised at drill, is, in truth, when applied in battle, not more efficient, perhaps less, than in two ranks. If therefore the expedient of forming battalions only in two ranks be resorted to, still the fronts of wings covering each other, and producing only a depth of four men, would be sufficient for troops so eminently qualified for battle as the British. This proposal of Jomini is an avowal of the inefficiency of dense columns, as they are usually formed by the French and other continental armies, in attacks and charges. If that general had been engaged against the British, he would have been still more convinced of this. During the late wars, not an instance occurred where a hostile *column, au pas de charge*, broke through a British *line*. And the charge at Maida by a brigade of light infantry, at Barossa by the 87th and three companies of the guards, at Vimiera by the 50th, and at Waterloo by the whole line, all in deployed order, two deep only, against lines or columns, demonstrates the error of supposing that a mass of human beings, possessed of individual will and feelings, can be subjected to the laws of mechanical action.

Rogniat, general of engineers, in the dispositions of the legion which he proposes, instead of battalions, contends for three ranks deployed, and the second line in columns, at quarter distance, ready to form squares when required; but both he and Jomini agree in the unprofitableness of fire from a third rank, in which they only maintain opinions that were long ago held by Folard, Saxe, and Lloyd.

Another system may be suggested, which would obviate many inconveniences under which the present labours. The present system of the infantry might be left such as habit, founded on experience, has framed it; with the exception of arming a third rank with rifled fusils, and spears about ten feet six inches in length: the fusil, when not used, to be slung on the shoulder in the manner of riflemen; and the spear with a spike to fix in the ground, and a hook about four and a half feet from the bottom, to serve for a rest in firing.[1] As light infantry now form nearly one third of the foot in armies, this species of troops should perform all their duties, and be exercised accordingly. When scattered in front, their fire from a rest would be more destructive; the spear would give them more confidence and security against light cavalry. When called back into line, they would give it solidity; and in a charge, their spears, reaching beyond the bayonets of the first rank, would render it doubly formidable. Being drilled to form in front or rear, they would be the first rank when the battalion forms square to resist cavalry. In pursuits, they alone should be let loose upon the enemy. By their institution, every battalion, every detachment, would have its proportion of light infantry. Intrenchments would be more obstinately defended, and breaches more easily stormed. If a rivulet were to be forded, their spears would sound for a passage on a whole line in a moment. On the outposts, three spears and two great-coats would form a tent. The idea is not new, for the Austrian militia in Hungary have a corps (Granitzer Schutzen) thus armed. Should the cuirassiers in the armies again resume the lance,—an event of some probability, since it is asserted that the Polish lancers of the guard of Napoleon, now in the Russian service, changed their small Ukraine horses for a larger breed about two years ago, with the intention of being converted into cuirassier lancers,—it may be foreseen that the spear will again be resumed in the infantry.

X. On the extensive subject of position we can only give some particulars.

1. The best military positions cannot cover a state merely by being occupied and maintained.

2. Every position has its key or decisive point, as before observed; but this point is not difficult to find. In a scattered line, it is in the centre; in a contiguous line, it will be found on that point where the nearest connection lies with the base of operations.

3. When an army occupies a position upon a height, or any other ground fit for a field of battle, it is important to have the front and flanks most carefully reconnoitred and watched, to prevent the enemy gaining either extremity of the line by a secret movement.

4. But as it is admitted, that to employ strong corps for that purpose, causes a useless waste of force, attracts the attention of the enemy, and does not, after all, secure the army from surprise, it is preferable to place small posts of observation in all the sinuosities of the ground, with orders to communicate with each other and with the army, or the nearest intermediate corps. These two latter rules were demonstrated by the surprise and attack of the Prussian army at Hochkirchen, of Korsakoff at Zürich, and Murat at Tarutina, but especially on the first-mentioned occasion; for, next to the battle of Leuthen, no instance produces more ample proof of the terrible effects of an army being surprised and taken in flank. The whole mass of Daun's forces was actually upon both flanks before they were discovered.

5. On ground of difficult access, such as vineyards, enclosures, gardens, steep heights, &c. the defensive order of battle should be in lines deployed two deep, covered by swarms of skirmishers. But the corps destined for attacks, and the reserves, are best in columns, formed on their centres, in the manner above described (IX.); for the reserves, being destined to fall upon the enemy at the critical moment, must advance with resolution and rapidity, that is, in column. If however it be desired to awe the enemy by a greater display of forces, the reserve may be deployed until the moment of attack.

6. A superior army should never wait to be attacked, still less wholly deploy into line, if compelled by circumstances to remain in its post. In this case no more troops should form line than are necessary to check the enemy. The remainder, formed into three or four heavy columns, should be placed ready to strike a decisive blow upon the most important point. A great army wholly deployed can no longer manœuvre with the same facility as columns; and

---

[1] As these troops would have no bayonet, they might be furnished with pontoneer swords, and saws and hatchets; both instruments of great utility in securing posts, clearing obstacles, and opening roads, and a thousand other daily wants. It is not meant that they should not have a drill of their own, and modes of formation independent of the battalion; but merely that, in giving or receiving charges in line or square, they should then constitute a third rank.

to nder troops not engaged immoveable, is repugnant to the est principles of tactics.

7 An army posted behind villages should cover the front wit them, by occupying the enclosures, &c. with some battali s of infantry, and the outlets with cannon. The first line hould be sufficiently near to sustain and be sustained by em, and also to provide the means of securing the eva ation of the place, in case the enemy should have gai d so much ground on other points as to be able to ma them. Villages, being liable to be turned, should not be ld by considerable corps of infantry, unless their topog phical situation should constitute them the key of the pos on, as was the case at Vimiera. The battle of Blenhei deserves attention on account of the consequences pro uced by the neglect of the principles applicable to villag .

8 When an army occupics a position perpendicular to a ri r, with a wing resting on the border, that wing should not e attacked, because, if the enemy changed front in mas towards the river, the attacking corps might be driven int t. On the contrary, if the onset is directed against the her wing with the principal mass of forces, that chance is i avour of the assailants; because the wing being turned, e whole line will be pressed towards the stream, and inc the risk of being destroyed. This would have been the se with Hiller's corps at Wagram, if a prompt retreat had ot saved it. Similar would have been the fate of the uni d French army at Talavera de la Reyna, had they persist in an attack upon the Spaniards; and they acted with gre judgment in directing their efforts solely towards Lord We ngton's left.

9 In the successful defence of a position, a repulsed attac hould not be pursued, unless that attack had been decisi ; because it might have been combined by the enemy r the purpose of drawing the defensive force out of its dvantageous ground. An untimely pursuit by the Au rian right lost the battle of Prague, and by the Saxon hat of Kesselsdorff, and again by the Austrian centre tha of Jemmappes.

Positions may sometimes be so arranged, that although the be scattered, they still possess the faculty of timely reu on. Several are indicated in Frederick's secret strateg l instructions, and one occurs when he besieged Olmu . Being greatly inferior to the enemy, who menaced hin from several quarters, he posted a corps at Littau, wh he remained in person with the covering army at Pr itz; and in order to connect the two masses at will, a s ll corps occupied the hill of Hrad, between Namiest an Laskow, to serve as an intermediate point. Order's we given to the corps at Littau, in case of attack, to retre towards him, and if a superior attack were made upon the overing army, he would retire towards the other; but if t ely information were received, all were to unite in the pos on of Gross Jenitz.

. As it is a maxim to operate against a weak part of the nemy's line, no position should be attacked upon its str gest point, as the Austrians did at Breslau; but if the hos e position be prolonged by a detached corps, the pri ipal effort should be directed against it; because, if tha be defeated, the main body is turned, and thereby wo ed.

. Armies may sometimes be posted behind a ridge of hil with defensive points upon their summits. These sh d not be attacked without an exact knowledge of the pos ion behind, and precautions to resist a counter moveme . The events of Austerlitz and on the Katsbach prove the ecessity of this precaution.

. No position or disposition of attack should be made wh e the line is intersected perpendicularly by a difficult ob cle, such as a river or morass; because the enemy ma act defensively on one side, and throw his whole mass on the other; as happened at Dresden, where the left wing of the allies was separated from the main body by the ravine of Plauen, and severely handled.

14. When an army remains immoveable in its position, both its flanks are liable to be turned. To obviate such manœuvres, others of a similar character should be opposed to them, as was done at Albuera. These counter-manœuvres are not difficult to execute, because the army turning a flank moves upon the arc, while the opponent takes the chord; consequently he is enabled to move a greater mass in less time, even when both parties are equal in forces. Rosbach, Vimiera, and Salamanca, are decisive examples, where the enemy moved in open day (which it is both difficult and dangerous to do in the night), and thereby rendered the counter-offensive both prompt and decisive.

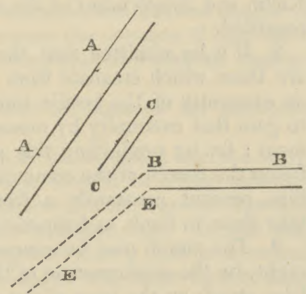
15. There are positions which cannot be turned nor attacked obliquely. If the stratagem to draw the enemy out of them does not take effect, a parallel attack with the centre reinforced is likely to be the best adapted to such circumstances. The dispositions of Marlborough at Blenheim were of this class, and deserve the study of military men.

On angles, or formation *en potence.*

1. Between two armies equally capable of manœuvring, the defensive one may form an angle with advantage to secure a flank from attack; but to render this precaution efficacious, the angle alone is not sufficient, because its utility is only momentary; the mass therefore should change front in the same direction, and present a whole line to the enemy.

2. If the army be sufficiently strong to assume the offensive against the assailant, a change of front, which is merely defensive, should be followed as soon as the angle is formed and the enemy checked, by placing the line in columns of divisions to the flank, and prolonging the direction from the position first occupied to gain the hostile flank. Thus taken in front by the angle, and in flank and rear by the new direction, the enemy will be defeated. In fig. 6, A is the army endeavouring to turn the left flank of B, which forms the angle C, and under the protection of this corps prolongs its line in the direction EE, by means of which the extremity of the hostile flank is gained. A cannot well oppose the execution of this movement in the presence of the angle C and of the line E, which, though it be in column, can form in an instant; hence A must fall back and change front also.

Fig. 6.

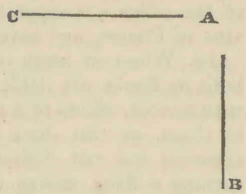


3. An angle to the front of the line or *potence*, such as the Austrians formed at Prague and Kollin, is not so serviceable as one thrown back to the rear; because the enemy can readily outflank its extremity from his position, while that extremity can be sustained but by slow degrees. Thus at Kollin, the Prussian cavalry turned it at the beginning of the action; and at Eylau, Benningsen repulsed the corps of Davoust on his left, and Ney on his right.

4. If a defensive position has an angle to the rear, the front will be weakened in proportion as that angle becomes more acute: but if there be a considerable interval on the summit, where the two lines should meet, the danger will be still greater; for if the enemy can establish himself on the point A, it is clear that the two wings, A C and A B, will be enfiladed, and forced to retreat;

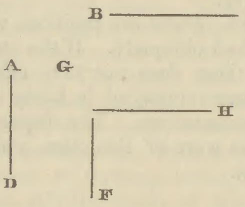
if not rolled up in confusion by an actual charge on either or both of these extremities. This caused the defeat of the Austrians at Prague, and of the Prussians at Breslau. Fig. 7.

Fig. 7.



5. If two allied armies or great corps take up positions forming a re-entering angle with a space between them, and some considerable obstacle masks that space, they expose themselves to be attacked and defeated separately: this danger increases with the increase of the distance between them. The corps A D being separated from B E by a wood, lake, or other considerable obstacle at G, the enemy F H, being covered by that obstacle, may attack and defeat one before the other can arrive to sustain it. Fig. 8. This principle results from the maxims of interior against exterior lines of operations. Such positions as these were occupied by Prince Henry and Hulsen, at Freyberg and Katzenhausern, with the Tharand forest, and, what was worse (at the distance of more than six leagues), with the Mulde, between them; yet the army of the empire, superior in force, remained three months before them, until Prince Henry moved and defeated it at Freyberg.

Fig. 8.



Oblique attack. General observations.

1. To insure the success of an attack, properly combined and reinforced on the essential point, it is necessary to refuse the weaker wing. This precaution is obvious, not only for the purpose of keeping a weaker part out of reach, but also because reinforcements are readily drawn from it to the point where the effort is making. Thus, instead of exposing it to be repulsed by superior forces, there is a real advantage in keeping it reserved to secure the victory. Leuthen affords a proof of the wisdom of such a disposition; Kollin and Jöegerndorf of the consequences when it is disregarded.

2. If it be admitted that the most advantageous attacks are those which emanate from a concentrated effort upon an extremity of the hostile line, it becomes indispensable to gain that extremity by measures which mask the movement; for by neglecting this precaution, the enemy may follow the march of the columns in their endeavours to turn him, present constantly a front, or even anticipate and take them in flank, as happened at Rosbach.

3. The march may be concealed by the darkness of the night, by the conformation of the ground, or by means of a false attack on the front of the enemy. The two last mentioned are to be preferred, because night marches are uncertain and even dangerous, slower and always more irregular, than those by day. For this purpose it is not necessary to march by lines, if the movement be masked by an attack of the advanced guard, while the mass advances towards the extremity desired, in columns of battalions at half distances. This will render it difficult to be discovered by the enemy in time to be counteracted.

4. In order to molest a greater space of front, instead of an advanced guard making a regular attack, it is preferable to employ a corps of light troops formed in parties, having points for re-assembling light cavalry, and some artillery to sustain them. This method is sure to distract the enemy's attention, and keep his whole line in check.

An oblique attack, according to Guibert and the *Journal Topographique*, is a disposition by which a part, or the choice of the forces, is advanced towards the enemy, and the other kept out of his reach. This definition is not quite correct, as figs. 9, 10, 11, and 12 demonstrate. An army may be out of reach of the enemy, and therefore refused in a line nearly parallel, and strongly reinforced on a wing, without being oblique. (Fig. 9.) It may also be in an inclined line on the head of the attacks, and form a positive diagonal, without being reinforced (fig. 10); or perpendicular upon a flank, as at Kunersdorff, with a wing reinforced (fig. 11); or horizontal upon the head of the columns without being oblique. (Fig. 12.) There are several modifications of these four orders (among others fig. 11); as, for example, a perpendicular angle to the front, as formed by the Austrians at Prague, Kollin, and Hochkirchen (fig. 13); the angle AC being perpendicular to the army DE, reinforces the right wing of the line AB without being oblique: so also an angle to the rear would reinforce the line without obliquity.

Fig. 9.

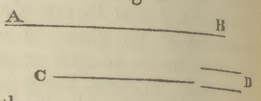


Fig. 10.

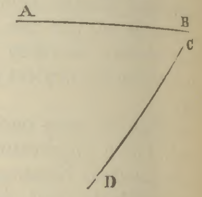

Fig. 11.

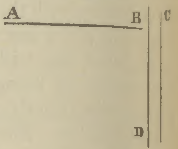

A parallel line, considerably reinforced upon the most important point, is no doubt good, and even very generally applicable; for it is conformable to the principle which forms the basis of all operations: but it has several inconveniences. The weak part of the line, being near the enemy, may be engaged, contrary to the intention, and be defeated; which event would balance and arrest the advantages gained on the other wing; as happened to both armies at Wagram. The reinforced wing having defeated its opponent, cannot take it in flank and rear without a considerable movement, which would separate it from the other, if already engaged. But admitting the weaker wing not to be engaged, the other cannot even then turn the flank without drawing it circularly along the hostile front, which the enemy must necessarily anticipate by being on the chord of the movement, and consequently give him the advantage of the offensive by reaching the decisive point first with the mass of his forces.

Fig. 12

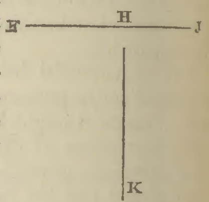

Fig. 13.

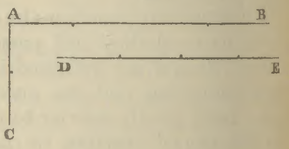
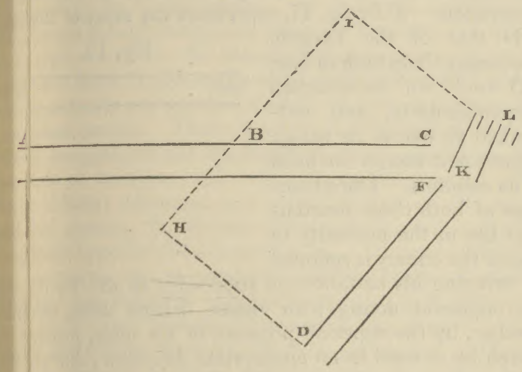


With the oblique order of Frederick, as applied at Leuthen, the effect is quite different; the extremity of the wing attacked is not only overpowered by a whole line, but the end of that wing is constantly outflanked, and the line turned, without manœuvre, or prolongation of direction, simply by a direct advance of the oblique line. The distance of the divisions which are not intended for the principal attack, places them out of the danger of being engaged by a superior force, and yet sustains the wing in action. These effects of the open oblique attack, although known, cannot be too often presented to the reflections of military men. They offer, besides, another advantage still more decisive, in bringing the half of the army constantly into action against the extremity, probably of only two brigades, of the hostile army, which has no counter-manœuvre to stop its progress. What troops can stand against such odds, when, besides, they are constantly outflanked and taken in reverse? Is it possible that confusion and dismay should not follow in a whole line, whose flank is overthrown, and menaced with total destruction, by the progressive advance in a direction upon the rear?

Yet such must be the infallible result of an oblique attack when once it has reached the flank of the opponent uncovered, as indicated in the preceding maxims; and when the lines are rapidly formed, according to the method of Frederick, as will be seen in the observations on marches. Fig. 14 demonstrates the mechanism more clearly. The

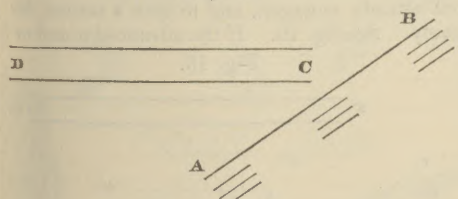
Fig. 14.



leftwing BC, of the army AC, will receive the fire of the second brigade of the army DKL, while the first brigade, or extreme right, formed in column of divisions, will turn it and decide the first attack with rapidity. The second brigade, in the oblique direction of its march, will soon be seconded by the third; and when that has passed the extremity, which must constantly recoil before a contiguous front the fourth brigade opens its fire; and in this manner, supposing the army DF, KL, arrived at the dotted line HI, the whole will have been engaged in succession with a fourth or a third of the enemy's line, the battalions of which, being crushed one after another, will be nearly surrounded.

This demonstration is sufficient to show the great advantage of an open oblique order of attack. It is called open, because the disposition, such as that of Leuthen, was nearly at right angles with the line of the Austrians, and different in every respect from a parallel order. All these advantages are equally applicable to masses concentrated upon the extremity which it is intended to crush. The army AB, fig. 15, instead of forming two lines, as in the former figure,

Fig. 15.



may draw up the first line only, and keep the second in columns at half distances behind the right, centre, and left, prepared to manœuvre or strike the decisive blow. These columns will be more moveable, and not being intended for the first attack, they will nevertheless cover it against counter-movements of the enemy. The battle of Salamanca offers a memorable lesson of this description, where the troops were concealed by the ground, and then suddenly brought in mass upon the enemy's left wing. That of the Kabach, almost the counterpart, was equally grounded upon these principles; both however with the difference, that the lead of the manœuvres was on the side of the adversary. Jomini, habituated to the lively national character of France, lays too much stress on the value of the lead in manœuvres, and therefore does not fully appreciate the powers of well-conducted counter-manœuvres, which the cool firmness of British and German soldiers can develope.

The battle of Leuthen furnishes another maxim equally important, namely, that an army with the flank resting upon an obstacle, such as the great pond of Gohlau, which covered the angle of Nadasti, may still be outflanked by an oblique attack. For this purpose, it is only necessary to mask the first brigade of the enemy by the nearest of the attacking corps, and move obliquely with the next, so as to press the principal effort upon the second. For the line being broken, the obstacle is no longer of any use; and the masked brigade is even in danger of being taken if not promptly withdrawn. But the manœuvre is not so advantageous as when the flank is still supported and easily turned.

On marches.

Marches in columns to the front, flank, or rear, which must be followed by deployment or echellon formations, are useful as parts of the elementary tactics; but never safely applicable near the enemy on a great scale, if they are at all complicated in the construction of the columns, or in the nature of the ground. Guibert devoted several volumes to their mechanism; but Tempelhoff alone has described the nature of Frederick's columns, by means of which his dispositions were executed with so much simplicity and precision. Although the present system of moving by corps has in a great measure superseded the old method of organization by lines, and consequently rendered the march-manœuvres, which triumphed at Rosbach, Leuthen, and Zorndorff, less applicable, they are still the best for such corps as are obliged to manœuvre in the presence of the enemy, whether it be to engage in front or to turn his flank.

On examining the mechanism of his columns at Kollin, Leuthen, &c., it will be perceived that his army, having broken into open columns, each line forming one by a mere wheel of divisions, right or left in front, by this method the army could,

1. Execute all the movements united without danger of being attacked in detail, because the columns of lines were at no farther distance than was required for actual engagement.

2. The enemy could neither cut them off nor penetrate between them.

3. In taking the direction of the intended line, the army, when moved to the ground, is formed in a few minutes, that is, in the space of time required for the word of command to pass down the column to wheel into line. In this method, the only precaution required was to send an advanced guard to protect the march, and at the same time to keep the enemy in suspense.

4. As the army requires only two or three hundred paces between the columns, and the divisions no more than their respective distances, to form into two lines, the manœuvre is easily executed with precision.

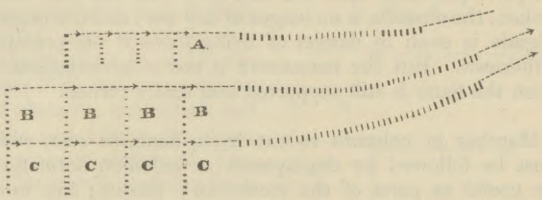
5. The army having reached the flank of the enemy by concealing the movement, as before noticed, and wheeling into line, will not allow the enemy time to form an angle, or to change front; consequently he will be overpowered in succession along his line.

6. To conclude, if two columns of the length of the line of battle are not immediately desired, or the ground requires a modification, four columns may be formed, by doubling up the lines, or by marching by wings, without increasing the difficulty of forming. The four columns being constructed of the two lines doubled, when arrived near the point where they are to form, the second and fourth halt until the first and third have proceeded so far

as to disengage from each other. While halted, they protect the march of the others, and when cleared by them, they follow in their rear, and thus are prepared to wheel into line with them.

If the columns are formed by wings, they will again fall into two lines by a simple change of direction, executed by all the heads of columns of each line at the same time to the right or left, and then leading into the rear of the preceding. But this transition of columns of wings into columns of line should take place at some distance from the enemy. At Leuthen, this manœuvre introduced the battle: fig. 16. A, the advanced guard masking the march of the army in four columns; B B B B, the heads of the four columns forming the first line; and C C C C, the heads of the second line (now in rear of the first), all changing direction by a wheel to the right at the same instant, and consequently forming two open columns ready to wheel into line. The advance mean time either halts in position to alarm the enemy on another point, or continues to open the march by preceding and covering it.

Fig. 16.



It is however evident that these kinds of marches must be made on open ground; for in countries deeply intersected, great movements are impracticable; and it thus becomes necessary to arrive by the openings which are known, and engage more or less in columns. By Guibert's and the regulation systems, the army being broken into several columns, they move with their heads often out of sight of each other at the distance of more than a mile, and yet they are expected to keep their alignments and relative distances. When ordered to form, they either close and deploy, or march by echellons to fit into an exact alignment. All this is evidently impossible before the enemy, who must discover the tedious manœuvre, and have time to act as he pleases while the numerous errors are rectifying; and if the centre divisions should be chosen for the points of deployment, half the columns must turn their backs upon his fire to perform it. Frederick, during the whole seven years' war, attempted these movements only twice; first in a combination with Bevern to attack Loudohn, which failed by the premature arrival of one column; and, secondly, at Torgau, which, as far as that manœuvre was concerned, failed also; for Zieten's column came too late, and was isolated. At Minden the French manœuvred in the same manner, and were a great part of the night and the next morning employed in rectifying the errors, which gave Prince Ferdinand time to arrive. It is true, he moved likewise in columns, but he had previously sent all the generals to reconnoitre their routes and points of formation, and cut openings and fix marks to insure the exact direction. Such precautions surpass even the underhand tricks to help the manœuvres in a camp of instruction; and the very precautions prove the impossibility of applying them in ordinary cases. During the revolutionary wars of France, all the belligerents met with failures from vain endeavours to apply them, notwithstanding that the new organization of corps and the use of swarms of skirmishers greatly facilitated their execution.

Lehwald's manœuvre at Jöegerndorf is worthy of notice, as particularly applicable in intersected ground. His infantry advanced in a double column from the centre, and formed to right and left without risk of confusion; the cavalry moving at some distance, easily took up the alignment.

The order of march on Frederick's system must however be considered only as a manœuvre, and not to be applied to marches in great operations.

As this order of march is best calculated for attacks against lines, so is it also upon columns in march. An attack upon an army while on the march is advantageous, for the same reasons as an attack upon an extremity of a line; because the army attacked on the heads of its columns is precisely in the same situation, relatively to the enemy, as one assailed in flank. The battle of Rosbach furnishes an illustration. A B, fig. 17, represents the army of the king, C D that of the French. Supposing them both in line, CD would still be attacked perpendicularly, and outflanked on one of its wings, exactly as it was on the head of its columns. The advantage of both these manœuvres lies in the necessity to which the enemy is reduced of bringing his battalions in succession to the front, while the opponent, acting with vigour, defeats them, one after another, by the superior pressure of his mass, provided its march be onward in an appropriate direction; horizontally if the column moves perpendicularly, and perpendicularly if the march is horizontal. The object for producing, as nearly as possible, an opposite direction, is to present a whole line to a head of a column, or to an extremity of a line; because, if both moved in a direction to meet with the heads of their columns, both would be obliged to deploy, and a parallel order would be the consequence, without tactical advantage to either army. In fig. 18, the columns AB meeting those of the enemy CD in the same order, both, fearing to be attacked, will immediately deploy; A B will therefore form the line FG, and CD the line HI, which gives no advantage to either party.

Fig. 17.

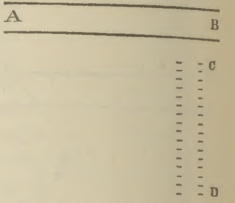


Fig. 18.

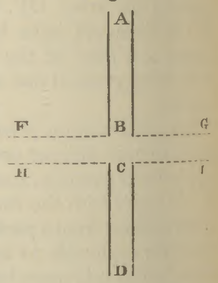
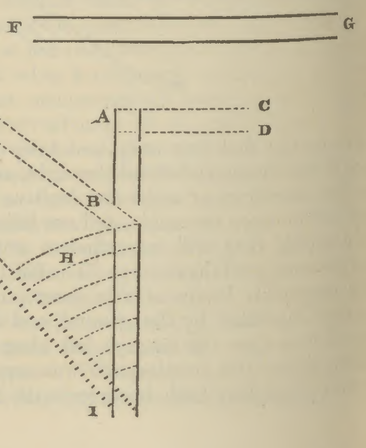


The battle of Rosbach offers a further illustration. As an angle must necessarily be formed when the heads of columns are attacked, to check the first efforts of the enemy, the advanced guard or leading brigade should deploy, while the rest of the army should take a new direction of march, clear of the enemy's flank, in order to protect the retreat of the advance already engaged, and to gain a station for acting offensively. See fig. 19. If the advanced guard or leading

Fig. 19.



brigades AB of the columns HI be attacked, a deployment must take place according to the direction of the attack CD. This manœuvre having checked the enemy FG, the army in the rear being thus momentarily protected, should immediately change direction exteriorly, by filing the divisions into a new alignment IL; or by altering the direction of the columns in a similar manner, so as to produce a prolongation beyond the enemy's flank KK. It is however clear that if the columns are left in front, the operation is according to rule; but if the right be in front, a direction to the left would present the reverse flanks to the enemy. There would be no time for a countermarch, and still less for wheeling up in succession. It therefore appears that the columns should change the pivots of divisions, and wheel to the right into line; for though this manœuvre would be against the letter of the regulations, no disorder would ensue, and it is actually practised, at least by cavalry, in some of the continental armies. There is no want of proofs of the occasional necessity of this manœuvre in every campaign; but the battle of Laswaree will suffice for an illustration. The British infantry advanced in a single column by the right, and after crossing the Mahnus Nye, a deep sunken rivulet, found itself opposite the enemy's right. To have prolonged the movement, was to produce a parallel order of battle; advantage was therefore taken of a ravine which led to the hostile right flank, and could conceal the movement. The head of the column turned to the left, and gained the flank; but when ordered to wheel into line, the pivots being reversed, some of the Sepoy troops, adhering to the letter of the rules and regulations, wheeled with their backs to the enemy.

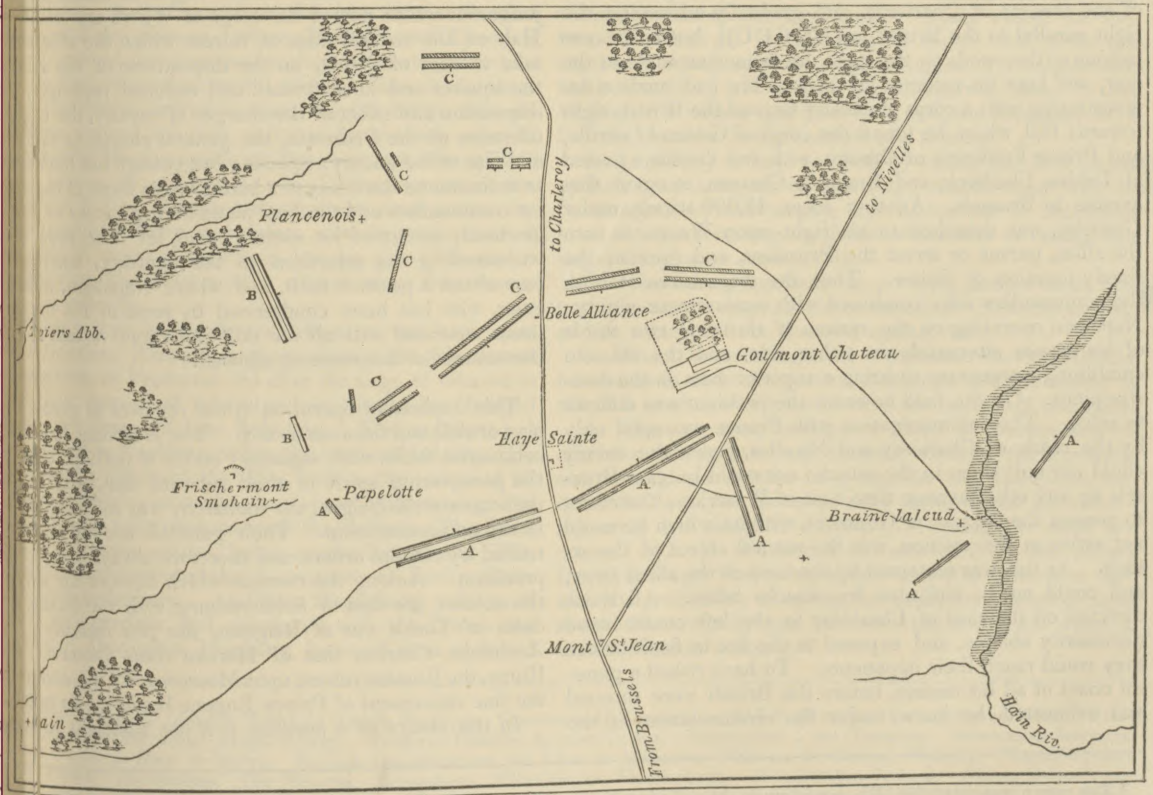
This method of converting a probable defeat into an offensive movement and oblique attack, will probably intimidate the enemy, and check his pursuit of AB, from the moment he perceives the menaced attack against his own flank. As a manœuvre it is also more rapid and simple than a change of front, which would only tend to a parallel formation. Although the existing modifications in the structure of armies, as already observed, renders this kind of attack more rare, and the organization by corps and divisions is advantageous to prevent them, it is nevertheless true, that the Prussians lost the battle of Auerstadt, and the French were placed in the most critical situations at Marengo, Eylau, and Lützen, because they were attacked on the march before they expected a general action.

Warlike Operations by Land.

Principles of dispositions at the battle of Waterloo.

The battle of Waterloo, unquestionably the most decisive event of the late awful contest, offers so many instructive circumstances, and so much matter for deep meditation, in the position and manœuvres, and in the exhibition of the soundest maxims of war, that it may be considered as a general illustration of the advanced state of the art of war at the present period. Without entering into details, the minutiæ of which are apt to confuse, we shall content ourselves with merely pointing out the principal dispositive features which it displays. As there are many plans more or less correct, and the ground is generally known, the remarks which we are about to offer will be readily understood by those who have any elementary knowledge of war. When Blucher had retreated from Ligny, and the duke of Wellington had fallen back from Quatre Bras, he occupied the position of Mont St Jean, determined to risk a battle with the forces he could collect on that point. Exclusively of the Prussians, whose severe loss in killed, wounded, and stragglers, could not immediately be reorganized or replaced, but by the expected arrival of the corps of Bulow, the duke's army consisted of about eighty-one battalions and eighty-seven squadrons; which, with the artillery, may have amounted to 66,700 men. Of these upwards of thirty battalions and as many squadrons had never been in action.

Fig. 20.



The letters A A A indicate the position of the British army, B B that of the Prussians, and C C C C that of the French.

This mass of forces was posted with the centre diagonally across and in front of the forking of the two causeways from Brussels to Charleroy and to Nivelles; the right centre behind the chateau of Goumont, and the left, considerably refused, passed in rear of La Haye Sainte, along the cross road in the direction of Ohain. Behind the right centre, Lord Hill placed his corps, *en potence*, in columns, prepared to manœuvre to his right, on the small plain of Braine la Leud; or to his left, to sustain the centre. In and about Braine la Leud was a Netherland division, with the right thrown forward, and covered by the rivulet Hain, and leaving the small plain open; a kind of gorge to tempt the enemy between the two sides of the re-entering angle of the right wing. The Prussians were expected to debouche through the woods of Lasne towards Planchenois, which would form the left into another gorge, or re-entering angle. Thus the position formed a kind of open W (fig. 20, A A A A, B B) with the chateau of Goumont at the summit of the salient angle, covered by a plantation of wood and enclosures, occupied by six or eight battalions; so that the enemy could not enfilade from behind that plantation, either of the faces of the centre, nor approach on either of the causeways which passed through the centre, without presenting his flank. Besides this point, La Haye Sainte, a stone farm close to the chaussé of Charleroy, and farther on the left the farm of Papelotte and chateau of Frichermont, were occupied. The whole front offered a gentle slope towards the enemy, and in the rear the cavalry was distributed in brigades, each in two lines, covered by the rising ground; and the artillery, all the field-pieces of which were nine-pounders or twelves, formed a line of almost contiguous batteries along the front, interspersed with howitzers and rockets.

By the returns found after the battle, it appears that the enemy had debouched from Charleroy with 122,000 men,[1] exclusive of the reinforcements that joined after the 15th of June. Of these he produced on the field of battle about 80,000 men, formed in concentrated masses on both sides of the chaussé of Charleroy, and gradually advancing the right parallel to the British left (C C C C); but as he was jealous of the woods on the right, he formed an angle to the rear, and kept his reserves far back. He had made a demonstration with a corps of cavalry beyond the British right towards Hal, where he found the corps of General Colville, and Prince Frederick of Orange, with two divisions posted at Tubise, Clabbeck, and Braine le Chateau, to cover that avenue to Brussels. Another corps, 42,000 strong, under Grouchy, was detached to his right upon Wavre, to turn the allies, pursue or arrest the Prussians, and prevent the timely junction of Bulow. Thus the dispositions of both the commanders were combined with consummate ability; Napoleon operating on the system of throwing two thirds of his masses alternately on either side, and the allies in combining manœuvres to bring a superior mass on the decisive point. On the field however the problem was difficult to solve. The communication with France was open only by the roads of Charleroy and Nivelles, hence the enemy could not quit them in the attack; nor could he gain Brussels by any other avenue than that of Waterloo; therefore, to possess the chateau of Goumont, without which he could not arrive at the position, was the natural object of the attack. As this was sustained by the mass of the allied army, and could not be enfiladed, his attacks failed. All those directed on the road of Charleroy to the left centre were necessarily oblique, and exposed to the fire in flank before they could reach their opponents. To have risked a general onset of all his masses, before the British were thinned and exhausted, he knew, under the circumstances of the moment, to be too hazardous. The plain of Braine la Leud appeared open. He could arrive by it; but that very circumstance proved that the enemy was prepared on that side. To have turned the force thither would in the first place have caused the loss of the communication by Charleroy, and next facilitated the junction of the Prussians; and, besides, the corps on the other side of the Hain flanked the advance, and could in a short time be sustained by the two divisions in its rear, and which he knew to be at hand. He would therefore have been placed between two fires, and have lost his point of retreat upon Charleroy; and the road by Nivelles might, meantime, be cut off by the troops left behind at Mons. Again, if he threw his masses towards the left, he only went to meet the Prussians, and left the British masters of the road of Nivelles, and possibly, if he advanced far, of that of Charleroy. He entangled himself in woods and defiles, where his superior cavalry could not act. The character of his opponent bespoke immediate offensive movements from the moment his right would be at liberty, therefore the chances were again in favour of the enemy; yet this was the only advantageous side, because it brought him nearer Grouchy, and in case of defeat he could take a new line of retreat by Namur. He however preferred the experiment which the enthusiastic valour of his troops might enable him to make; and this committed him so deeply, that, when at length the Prussians appeared, a retreat was no longer possible.

These observations disprove the ignorant assertion, that little skill was displayed on either side. The generals and the soldiers equally did their duty: the veteran Blucher behaved with just prudence in keeping so long back from the dangerous manœuvre which was assigned him; and when he saw the hostile cavalry destroyed, he acted with vigour and skill. As for Grouchy, who wasted his time in forcing the position of Wavre across the Dyle, everywhere fordable, his manœuvres show that he felt the danger of his movement, and he wisely remained on the banks. Much might be added upon the judgment which posted the corps at Wavre and another at Hal, on the several lines of retreat which the allies could take in case of defeat, on the dispositions of the artillery, the squares and lines formed and reduced repeatedly, the disposition and effect of the charges of cavalry, the counter-offensive of the Prussians, the general charge to the front, and fate of the enemy's squares; but enough has been stated to recommend the study of a battle where three of the greatest commanders and the best manœuvring armies in Europe gloriously struggled for victory; and, let it be added, notwithstanding the assertions to the contrary, where none committed a positive fault, and where Napoleon, in particular, who has been condemned by some of his own partisans, operated with all the skill and vigour which the circumstances of the moment allowed.

This unpleasant operation in war requires as great a display of skill and firmness as any. The Austrians have often conducted theirs with sagacity; and it is perhaps owing to the persevering spirit of their retreats, that, after twenty unfortunate campaigns, the monarchy was as formidable as in the commencement. Their generals are not then controlled by cabinet orders, and therefore always operate with precision. Among the retreats which deserve the study of the soldier, are that of Schulemburg with the Saxons, the duke of York's out of Belgium, the two retreats of the Archduke Charles, that of Moreau from Bavaria to the Rhine, the Russian retreat upon Moscow and Tula, and, lastly, the fine movement of Prince Eugene Beauharnois in Italy.

In the choice of a position, it is not sufficient to have a strong front and secure flanks; the means of retreating must also be considered in case of defeat. Lloyd, in his "Reflections on the Battle of Kollin," observes that a defeated army retires with greater facility by dividing itself into as many corps as the nature of the country will allow; because, 1st, if the enemy form an equal number of divisions, he cannot operate vigorously upon any, and the retiring army having the facility of *reuniting*, may totally defeat one of the hostile corps; 2d, if the enemy operates *en masse*, it can be only towards one, and the others fall back unmolested: that division, however, covered by a strong rear guard, avoids serious actions, and having the faculty of moving more rapidly because it is less numerous, can escape likewise without great loss. Bulow, taking up this question mathematically, advances the opinion that the columns should move outward or eccentrically, from a point towards the periphery; but Jomini combats both so far victoriously. He observes, that Lloyd admits that the division of the pursuing forces exposes them to defeat; why then recommend such a manœuvre to a retreating army, which must be already inferior to the enemy? He quotes the fine concentric retreat of the Archduke Charles, and might have added the Russian and both Lord Wellington's. But in examining the mechanism of these movements, it appears that none of them was the consequence of a defeat, and especially such defeats as the modern system of attack inflicts; they were merely armies manœuvring back towards their base upon their own lines of operations, watching a favourable opportunity to resume the offensive; or retreats after battles when both parties had claims to the victory, as Benningsen's after Eylau, and Kutusoff's after Borodino. The difference between Lloyd and Jomini is merely in words; for the former points out the facility of uniting two corps, which, if he meant the eccentricity applied by Bulow, would be impossible.

---

[1] The return was dated the 13th, according to the assertion of a Prussian officer of the staff. The whole force brought over the frontier must therefore have amounted to nearly 150,000 men.

But an army completely defeated is no longer in the hands of the general, whether he be the duke of Brunswick or Napoleon. A check, such as the Austrians suffered at Fleurus, and the allies at Lützen, Bautzen, and Dresden, does not prevent the commander from executing the best measures that circumstances will allow. Thus, in the three former the armies retired in mass; in the latter, they divided into several columns, and thereby not only covered themselves by the mountains of Bohemia, but also applied Lloyd's maxim, in uniting two corps to destroy one of the pursuer's at Kulm. Hence circumstances must govern the measure; and if, after a real defeat, a broad river, chain of mountains, or range of fortresses, can be gained in two or three marches, the division of a routed army may be applied as a safe rule.

A retiring army is not always obliged to fall back upon its own frontier; it may sometimes change the direction of its operations, as Frederick did after the siege of Olmutz in 1758, when, instead of returning into Silesia, he changed his line, and marched into Bohemia. This measure was also proposed to Napoleon before the battle of Leipzig. He was advised to approach the Elbe, call in the corps of St Cyr from Dresden, cross the river about Wittemberg, and descend by the right bank towards Magdeburg. The Prussian and northern armies, being on the left of the Elbe, could not have prevented the destruction of Berlin, Potsdam, and Brandenburg. And from Magdeburg, reinforced with its vast garrison, and connected with the Danes and the corps of Davoust at Hamburg, he could have operated by a new line, having his communications open by Wesel, Cassel, and all the fortresses of Holland; the sterile country to which the allies must have followed him could not have subsisted their vast cavalry; and the sandy roads would hardly have allowed sufficient transport of provision to maintain the troops. There were however many, and probably superior reasons, which made him reject the proposal.

Pursuits.

If the art of war consists in applying the superior force of a mass upon a weak point of the enemy, it follows that a defeated army should be pursued with the utmost vivacity. Never delay till to-morrow, is an ancient military maxim, applicable especially in pursuit; for the strength of an army consists in its organization, in the unity resulting from the connection of all its parts with the mainspring which makes it move. After a defeat, this unity no longer exists. The harmony between the head which combines, and the body which executes, is broken; their connection is suspended, often destroyed. To pursue and attack is to march to a certain triumph. All the late campaigns offer signal examples of this truth. Generals of mediocrity often neglect this maxim, and their victories are scarcely more than a forcible removal of troops. The direction of the pursuit, though guided by circumstances, should always however aim at gaining the hostile line of communications, and cutting off the enemy from his base; because, by so doing, he may be thrown upon such obstacles as to force him to surrender.

Sieges.

Sieges, according to Lloyd, should never be undertaken but with the following views: 1st, when fortresses are situate upon the passages which lead to the enemy, so as to render it impossible to penetrate without capturing them; 2d, when they intercept the communications, and the country is unable to furnish the necessary subsistence; 3d, when they are wanted to cover magazines formed in the country, and thereby to facilitate the operations; 4th, when the enemy has considerable depots within the fortress, of which he is absolutely in want; 5th, when the capture of a fortress produces the conquest of a considerable tract of country, and enables the besiegers to winter in that vicinity. To these may be added, 6th, the recapture of a fortress essential in the defence of a frontier.

Covering sieges.

1. As victory is best secured by taking the lead in an operation, an army covering a siege should never wait to be attacked by the enemy, but endeavour to anticipate him; for, by defeating the forces which aim at raising the siege, the place is sure to fall.

2. If the enemy approach the covering army with an imposing mass, the siege should be raised, all the forces united, and an attack in force directed against him.

3. When the relieving army is defeated, the siege should be resumed, while the pursuit continues, and the enemy is not in a condition to return before the capture of the place.

4. When an army besieges a place, in consequence of offensive movements and anterior success, the covering army should not remain in a position near the place, but drive the enemy as far as possible forward; for the relieving army will find the difficulty of raising the siege increased with the distance it is removed from the place; but if at length that army should arrive so near as to furnish the probability of raising the siege, the besieging corps should then rapidly join the covering army, and make a united effort to defeat it.[1]

Warlike Operations at Sea.

PART II.—WARLIKE OPERATIONS AT SEA.

Referring generally to the articles Admiral and Admiralty, Docks, Navigation, Navy, Seamanship, Ship-Building, Signals, and Telegraph, for much that appertains to naval war, we shall here direct our attention to that branch of the subject which is commonly designated *Naval Tactics.* By this term is understood the art of arranging fleets or squadrons in such an order or disposition as may be most convenient for attacking the enemy, defending themselves, or of retreating with the greatest advantage. Naval tactics are founded on those principles which time and experience have enabled us to deduce from the improved state of modern naval warfare, which has occasioned, not only a difference in the mode of constructing and working ships, but even in the total disposition and regulation of fleets and squadrons. We here propose to lay down the general principles of naval tactics, and to describe, as briefly as is consistent with perspicuity, the most improved systems which have been adopted in modern times.

Ordinary division of fleets.

Fleets are generally divided into three squadrons, the van, centre, and rear, each under the command of a flag-officer. The admiral of the fleet, or chief in command, leads the centre division, while the van is usually commanded by a vice-admiral, and the rear by a rear-admiral. Each squadron is distinguished by the position of the colours in the ships of which it is composed. Thus, the ships of the centre squadron carry their pendants at the main-top-gallant mast head, while those of the van division have their pendants at the fore-top-gallant mast head, and those of the rear at the mizen-top-mast head. Each squadron, as far as possible, consists of the same number of ships, and as nearly as may be of the same force. In large fleets, the squadrons are sometimes again divided in a similar manner; the van and rear of the squadron being headed by rear-admirals, or senior captains, called commodores. In the usual mode of forming the lines, each commanding admiral arranges his ship in the centre of his own squadron, and thus the admiral of the fleet is in the centre of the line. When no enemy is in sight, the sloops, store-ships, fire-ships, and other small vessels, are dispersed to windward of the fleet, that they may be more easily supported, and more readily answer signals. The frigates lie to windward of the van and rear of the convoy, thus keeping a good look-out, and keeping the small vessels in their proper station. When the fleet sails in three columns, the centre still keeps in the middle, while the van and rear form the starboard or the larboard column, according to circumstances. These arrangements are called orders of sailing, and will be better understood from the following definitions.

Definitions.

The *starboard line of bearing* is that line on which the arranged ships of a fleet bear from each other on a close-hauled line, whatever course they may be steering, so that when the ships haul their wind, or tack together, they may be on a line close hauled upon the starboard tack. The *larboard line of bearing* is that line on which the ships, when hauling their wind, or tacking together, may be formed on a line close hauled on the larboard tack. The ships of a fleet are said to be on *a line abreast* when their keels are parallel to each other, and their main-masts lie in the same straight line. Ships are said to be in a line on the bow or quarter when they are arranged in a straight line cutting their keels obliquely in the same angle, so that, reckoning from any intermediate ship, the ships towards one extremity of the line will be on the bow of that ship, while those towards the other extremity will be on her quarter. When several ships in the same line steer the same course, while that course is different from the line of sailing, they are said to sail chequerwise.

When the ships of a fleet arranged in any of the orders of sailing, and on the same line, perform successively the same manœuvre, as each gets into the wake of the ship that leads the van of the line or squadron, tacking or veering, bearing away or coming to the wind in the same point of the wake of the leading ship, they are said to *manœuvre in succession.*

There are usually reckoned five orders of sailing, exclusive of the line of battle, the order of retreat, &c. In the first order (see figs. 1 and 2), the fleet is arranged on the *starboard* or *larboard* line of bearing, all the ships steering the same course. In these cases the fleet, by hauling the wind when in the starboard line, as in fig. 1, will be ready to form the line on the starboard tack; and when ranged on the larboard line of bearing, as in fig. 2, it will, by tacking, be ready to form the line on the larboard tack. The arrows annexed to the diagrams mark the direction of the wind, as in ordinary charts.

Fig. 1.

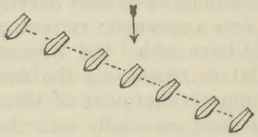

Fig. 2.

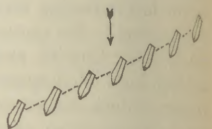
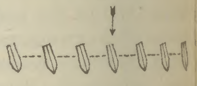


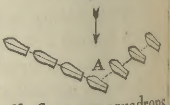
This first order of sailing is now seldom employed, except in passing through a narrow strait. In the second order of sailing, the fleet steering any proper course, is ranged in a line perpendicular to the direction of the wind, as in fig. 3. This second order, besides being equally defective with the former, is subject to the additional disadvantage of rendering it extremely difficult for the ships to tack, without each ship falling on board that next astern.

Fig. 3.



In the third order of sailing, the whole fleet is close hauled, and ranged on the two lines of bearing, so as to form an angle of twelve points, having the admiral's ship (A, fig. 4) in the angular point, and the whole fleet steering the same course. Thus, supposing, as in the figure, the wind at north, the starboard division of the fleet will bear W. N. W. of the admiral, and the larboard E. N. E. This order in small fleets or squadrons is superior to either of the former; but when the fleet is numerous, the line will be too much extended.

Fig. 4.



In the fourth order, the fleet is divided into six or more columns, and is thus more concentrated. The commanders, ranged on the two lines of bearing, have their squadrons astern of them, on two lines parallel to the direction of the wind; the first ships of each column being, with respect to the commander of the squadron, the one on his starboard and the other on his larboard quarter. The distance between the columns should be such that the fleet may

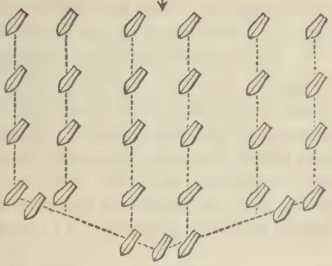
---

Précis des Evenemens Militaires. Coxe's Life of Marlborough. Pasley's Essay on the Military Policy and Institutions of the British Empire. Jones's Journals of Sieges.

The foregoing part of this article was written for the Supplement to the former editions, by Lieutenant-Colonel Charles Hamilton Smith. The part that follows, *on Naval Tactics,* was written by one of the contributors to the fourth edition, but of whose name we are not accurately informed.

readily be reduced to the third order of sailing, and from that to the order of battle. This order is adapted for fleets or convoys crossing the ocean, and is represented in fig. 5. But as it requires much time to reduce a fleet from this order to that of battle, it is defective when in presence of an enemy.

Fig. 5.



In the fifth order, the fleet, close hauled, is arranged in three columns parallel to each other, the van commonly forming the weather, and the rear the lee column. See fig. 6. Fig. represents the same order, except that each column is here subdivided into two, with the ship bearing the commander of each squadron in the centre of each subdivision.

Fig. 6.

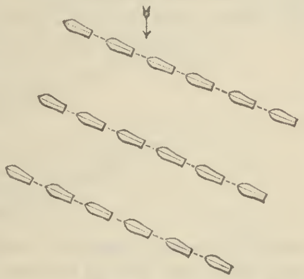


Fig. 7.

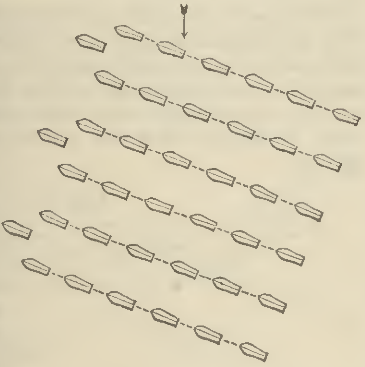
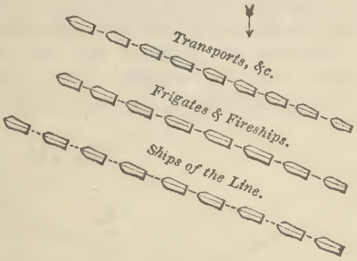


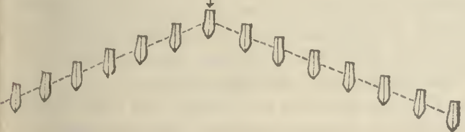
In forming the order of line of battle, the ships of the fleet are drawn up in a line bearing close hauled, standing under easy sail, so that each ship may be at a certain distance from the ship immediately ahead, as a cable's length, or half that distance. The fire-ships and frigates ahead and astern, form a line parallel to the former, and to the windward of it if the enemy be to the leeward, but to the leeward if the enemy be to windward. This order is denoted by fig. where the fleet is sailing on the starboard tack, with the wind at north.

Fig. 8.



When a fleet is compelled to retreat before a superior force, it is usually arranged in an order the reverse of the third order of sailing; the divisions of the fleet being ranged in the two lines of bearing, so as to form an angle of 135° or twelve points, the admiral's ship being in the angular point, and the frigates, transports, &c. included within the wings to leeward. See fig. 9, where the fleet is sailing right before the wind.

Fig. 9.



Warlike Operations at Sea.

Though any other direction may be taken, the two lines still form the same angle.

Order of convoy.

The order of convoy is that in which the ships are all in each other's wake, steering in the same point of the compass, and forming a right line. If the fleet is numerous, it may be divided into three columns, which are to be ranged parallel to each other, that of the admiral occupying the centre, and all steering the same course.

Having thus described the ordinary positions of a fleet, we must explain the manœuvres by which they are produced, and we shall begin with the orders of sailing.

Method of forming the first order of sailing.

To form a fleet in the first order of sailing, supposing the ships to be in no particular order, that ship which is to lead on the proposed line of bearing for the order of sailing, runs to leeward of the greater part of the fleet, and then hauls her wind under an easy sail. Each of the other ships then proceeds to take the proper station, by chasing the ship which is to be ahead of her, and when in the wake of the leading ship, adjusts her quantity of canvass so as to preserve the proper distance. The ships thus arranged astern of each other are in the line of battle; and from this the first order of sailing is formed, by each ship bearing away at the same time, and all steering the proposed course.

Second order of sailing.

In forming the second order of sailing, the leading ship runs to leeward of so many of the fleet that each ship may readily fetch her wake, and then steers a course eight points from the wind, under an easy sail. The line is formed by each ship in the same manner as in the first order, except that, before bearing away, the line is perpendicular to the direction of the wind, or each ship has the wind on her beam.

Third order.

As, in the third order of sailing, the admiral's ship is in the centre, to produce this position, the fleet being formed in a line on one of the lines of bearing, and the ships steering in each other's wake, ten points from the wind, the leading or leewardmost ship first hauls her wind. The second ship does the same as soon as she gets into the wake of the former; and this is done by each ship till the admiral's ships haul their wind, when they reach the wake of the leading ship. At the same time that the admiral's ship hauls her wind, the sternmost half of the fleet does the same. The ships are now in the third order of sailing, from which the fleet can be formed in the line of battle on either tack.

Fourth order.

To form the fourth order of sailing, the commanding admirals range themselves on the two lines of bearing, at a proper distance from each other, steering the proposed course; and the ships of the several columns take their respective places, parallel to each other, and forming lines in the direction of the wind.

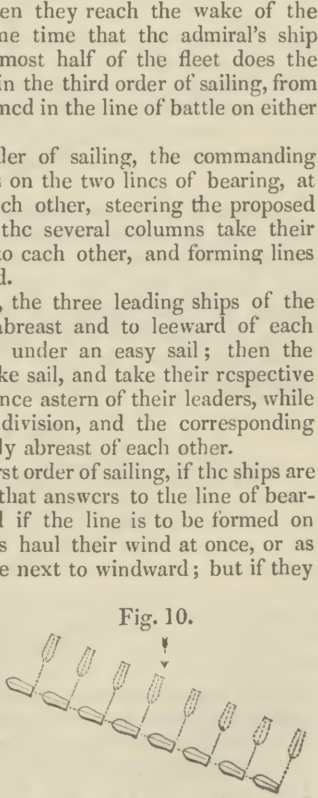
Fifth order.

To form the fifth order, the three leading ships of the divisions take their posts abreast and to leeward of each other, keeping their wind under an easy sail; then the ships of each squadron make sail, and take their respective stations at the proper distance astern of their leaders, while the commanders of each division, and the corresponding ships of each, keep mutually abreast of each other.

To form the line of battle.

1. In forming from the first order of sailing, if the ships are running large on the tack that answers to the line of bearing on which they sail, and if the line is to be formed on the same tack, all the ships haul their wind at once, or as quickly as possible after the next to windward; but if they be on the other tack with respect to the line of bearing, they all haul their wind and tack or veer together. If the line of battle is to be formed on the other line of bearing, the ship most to leewards veers or tacks, and hauls her wind, while

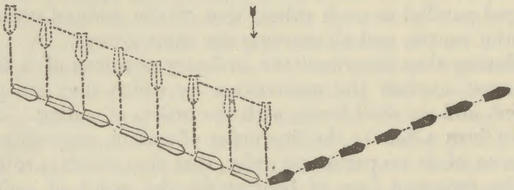
Fig. 10.



Warlike Operations at Sea.

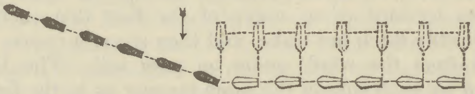
the rest of the fleet veer or tack at the same time, and steer with the wind four points free, and each ship hauls her wind as soon as she gets within the wake of the leader. See figs. 10 and 11.

Fig. 11.



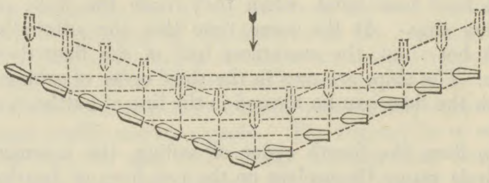
Suppose the fleet running before the wind in the second order of sailing. To form the line from this position, all the ships haul up together on the proper tack, presenting their heads eight points from the wind at the line on which they are arranged; the leading ship then hauls her wind, immediately making sail or shortening sail, so as to close or open the order, and the same is done successively by all the rest. See fig. 12.

Fig. 12.



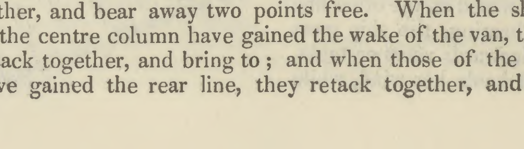
In a fleet running large in the third order, the line of battle is formed by the wing which is in the line of bearing corresponding to the tack on which the line is to be formed, and the ship at the angle, hauling their wind together, while the ships of the other wing haul up together eight points from the wind; each ship moving in this direction till she reach the wake of the other wing, when she hauls close up. See fig. 13.

Fig. 13.



In forming the line of battle on the same tack from the fifth order of sailing (as the fourth is not calculated for forming a line of battle), the centre brings to, so as only to keep steerage way; the weather column bears away two points, and when it gets ahead of the centre, hauls its wind, while the ships of the lee column tack together, and crowd sail to gain the wake of the centre, when they retack together, and complete the line (see fig. 14); or the

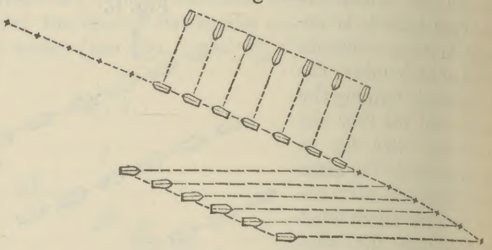
Fig. 14.



weather column brings to, while the centre and lee tack together, and bear away two points free. When the ships of the centre column have gained the wake of the van, they retack together, and bring to; and when those of the lee have gained the rear line, they retack together, and all stand on; or, lastly, the lee column brings to, the centre runs under easy sail two points free, to get ahead of the rear squadron, while the rear bears away under a press of sail two points free, to get ahead of the centre division.

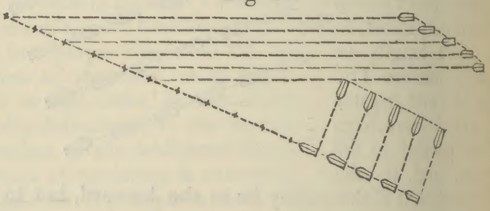
2. Suppose the weather and centre columns to interchange. To form the lee under these circumstances, the centre stands on, while the weather column bears away eight points, and having reached the wake of the centre, which now forms the van, hauls up; the ships of the lee column tack together, and run under a press of sail, within two points free, so as just to gain the rear of the line when they retack together (see fig. 15); or the lee column brings to, while the centre squadron bears away three points under easy sail, and having reached the wake of the van, hauls up to form the centre division.

Fig. 15.



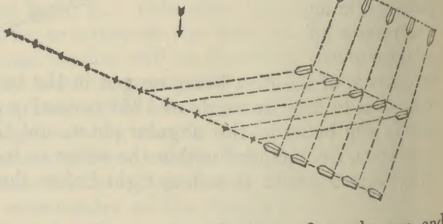
3. Suppose the centre and lee columns to interchange. The lee column stands on close hauled under an easy sail; the weather column bears away two points under a press of sail, till it reach the head of the line, when it hauls up; and the centre bears away eight points, and when in the wake of the lee, now the centre, hauls its wind. See fig. 16.

Fig. 16.



4. If the weather and lee columns interchange, the lee column stands on under a press of sail close hauled, while the centre, under easy sail, bears away two points, and when it reaches the wake of the now van squadron, hauls its wind; and the weather column bears away eight points, hauling up when in the wake of the centre. See fig. 17.

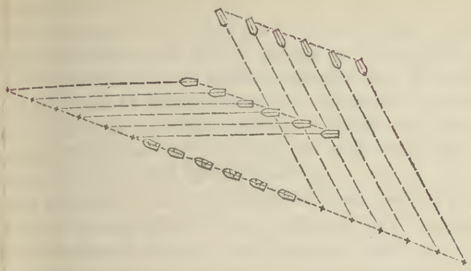
Fig. 17.



5. Suppose the centre column to form the van, and the weather the rear division. Here the lee column brings to, while the centre bears away two points, forming the line ahead of the former, now the centre; and the weather column veers away seven points on the other tack, forming the rear squadron. See fig. 18.

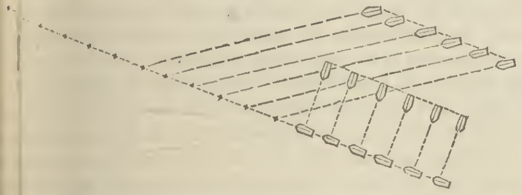
6. To form the line so that the lee column may form the van, and the centre the rear, the lee column is to stand

Fig. 18.



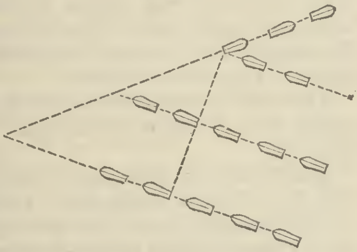
on der a press of sail, while the weather bears away thre points under easy sail, and the centre bears away eight poi , the ships of each column hauling their wind when in t wake of the now van division. See fig. 19.

Fig. 19.



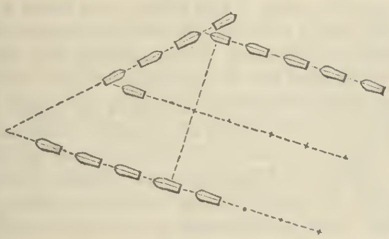
If the line of battle is to be formed on the other tack, so at the weather shall form the van division, as in the firs case, the ships of the weather column first tack succes vely, while those of the centre and lee stand on, the for er under easy sai and the latter sho ening sail, the lea ng ships tacking wh in the wake of th now van, taking gre care that the shi of the centre and lee raw not too near to e sternmost ships of e van, or to each oth r. See fig. 20.

Fig. 20.



To form the line on e other tack, when the centre and weather columns in change, the weather column brings to, while the ce re column stands on, till the leading ship be fully able to ear the weath column, when th ships of the ce re tack succe vely as they re h the wake of th van. The lee co mn stands on, ta ing successi ly as the ships ge into the wake of he van, under m erate sail. See fi 21.

Fig. 21.



. In forming the line on the other tack, when the centre a lee interchange, the centre brings to, while the ships o he weather tack under shortened sail, and the lee under a ess of sail stands on; the leading ship having gained the w e of the line, tacks, and is followed in succession by her d sion. The centre column fills and stands on, when the fi ship of that column, and the last of the lee, bear from e h other in a direction perpendicular to that of the wind. S fig. 22.

0. To form on this same tack, so that the weather and lee may interchange, the weather and centre bring to, while the lee crowds sail till it can pass ahead of the weather column, when the ships tack in succession. As soon as the leading ship of the centre, and the last of the lee, bear from each other in a line perpendicular to the wind, the centre fills, and tacks in succession when in the wake of the now van; and the ships of the weather column do the same when their leading ship and the last of the centre are under similar circumstances. See fig. 23.

Fig. 22.

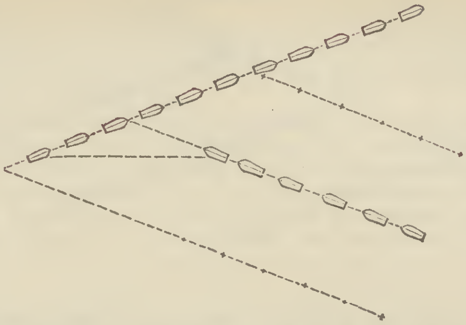


Fig. 23.

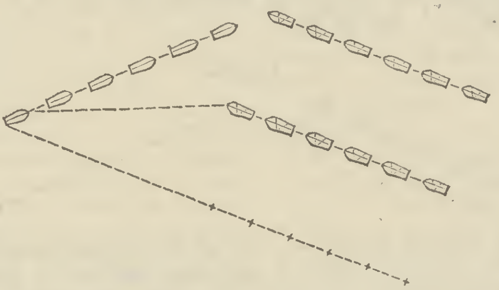
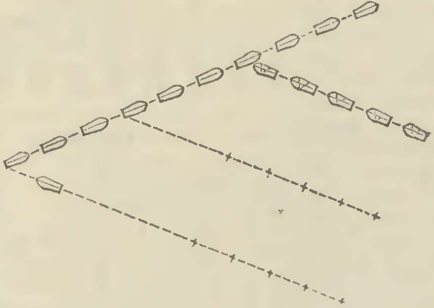


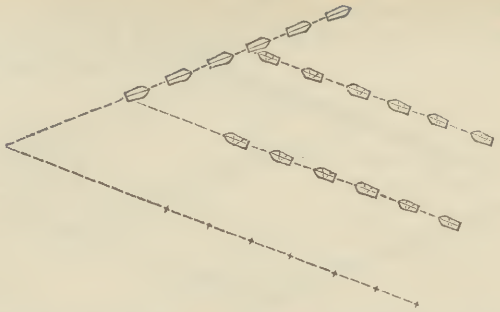
11. Suppose the centre is to form the van, and the weather the rear, in forming the line on the other tack. The weather brings to, while the other columns make sail till they can pass ahead of the former on the other tack, when they tack successively. The weather column, when the others have passed it, fills, and tacks to form the rear. See fig. 24.

Fig. 24.



12. Suppose now the lee column is to form the van. The weather and centre bring to, while the lee crowds sail, and tacks when it can pass ahead of the weather column. When the last ship of the now van has passed to windward of the former weather column, the van shortens sail, to give time for the other columns to form, and the weather and centre fill at the same time, to gain the wake of the van, when they tack in succession. See fig. 25.

Fig. 25.



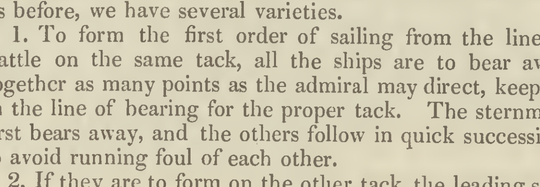
To form the orders of sailing from the line of battle.

We must now show how a fleet may be disposed in the principal orders of sailing from the line of battle; and here, as before, we have several varieties.

1. To form the first order of sailing from the line of battle on the same tack, all the ships are to bear away together as many points as the admiral may direct, keeping in the line of bearing for the proper tack. The sternmost first bears away, and the others follow in quick succession, to avoid running foul of each other.

2. If they are to form on the other tack, the leading ship bears away four points to leeward, and the rest follow in succession. The sternmost ship having bore away, the whole haul up, and will be in bearing for the line on the other tack. See fig. 26.

Fig. 26.



3. To form the second order of sailing from the line of battle, the whole fleet is to bear away together ten points, so that when the headmost ship, which first presses sail, shall come abreast of the second ship, the second ship must adapt her sail to keep in this bearing, and so in succession, each taking care to keep the preceding ship in a line with herself, perpendicular to the direction of the wind. The whole fleet will now be before the wind. See fig. 27.

4. To form the third order, the whole fleet is to bear away together ten points, the headmost half, including the centre ship, carrying a degree of sail to preserve their line of bearing, while each of the remaining ships is successively to shorten sail, so as to form the other line of bearing with respect to that on which they were before arranged. See fig. 28.

Fig. 27.

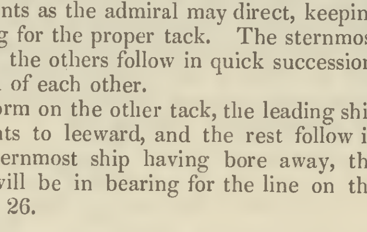


Fig. 28.

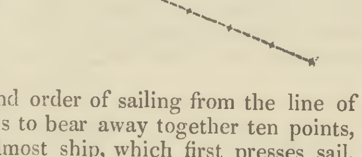


5. To change from the line of battle to the fifth order on the same tack. Of this evolution there are several varieties, but we shall mention only two; first, when the van is to form the weather, and the rear the lee column, and the fleet to keep as much as possible to windward. In this case the van and centre tack together, and run close hauled in bow and quarter line, while the rear proceeds in its former course under easy sail. When each ship of the centre is abreast of the corresponding ship of the rear, the centre retacks, while the van stands on till the centre and rear come up, when it also retacks, and all the columns regulate their distances. Secondly, when the van is to form the lee, and the rear the weather column, the van bears away under easy sail, and goes at right angles with the line ahead, while the centre runs two points free, each ship steering for that ship of the van which is to be abreast of her when in column. The distance must be determined by the leader of the van, who is not to haul up with her division till she and the sternmost ship of the centre column are in a line at right angles with the wind, when both stand on under easy sail, while the rear crowds sail to pass to windward of both.

6. To form the fifth order of sailing from the line of battle on the other tack. Of this there are also several varieties, but we shall confine ourselves to two. First, when the van is to form the weather, and the rear the lee column, the van tacks in succession, while the leading ship of the centre is to tack when the leader of the van passes him exactly to windward, in which she is followed by her division, and the rear manœuvres in the same manner with respect to the centre. Secondly, when the rear is to form the weather and the van the lee column, the van tacks in succession, and when about, either shortens sail or brings to, to allow the other columns time to form. The centre and rear then crowd sail, and tack in succession; the former tacking when its leader has the centre of the lee column in a line at right angles with the wind, or when its centre passes astern of the lee column. When the centre has tacked, it regulates its rate of sailing by the lee, and both wait for the rear to pass to windward. The rear tacks when the leader has the first ship of the lee in a line at right angles with the wind, or when its centre ship passes astern of the centre column.

To nœ lin bat

There are various evolutions or manœuvres performed by a fleet when in line of battle, some of which we must here describe.

Sometimes the fleet has to form the line on the other tack, by tacking in succession. To do this, the leading ship of the fleet tacks first, after making more sail, or after the second has shortened sail, to increase the interval between them. When the first ship is about, either the second makes more sail, or the third shortens sail, and as soon as the second gets into the wake of the leader, she tacks, putting down the helm just as she opens the weather quarter of the first ship, already on the other tack. In the same manner, each of the other ships tacks when in the wake of the leader; and the ships already about must preserve their proper distances, by shortening sail, if necessary, till the whole fleet be on the other tack. If a ship should miss stays, she must immediately fill again on the same tack, and make sail with all possible expedition, taking care not to fall to leeward. Thus she will get ahead and to windward of the following ships, which will successively perform their evolutions in the wake of the ships that are already on the other tack, standing on rather farther than if the ship ahead had not missed stays.

But suppose the ships are not to tack in succession. To form the line on the other tack, the whole fleet veers together; the rear ship hauls her wind on the other tack, and stands on, while the rest go two points free on the other tack, and haul up as they successively gain the wake of the leading ship.

If the line is to veer in succession, the van ship veers, and stands four points free on the other tack, hauling her wind when clear of the sternmost ship, and the rest follow and haul up in succession.

Sometimes the fleet has to turn to windward while in line of b tle. The best way to do this, when there is good sea- om, is for all the ships to tack together, when the fleet ill be in a line of battle on the one board, and in bow and uarter line on the other. If however the fleet be turn g to windward in a narrow channel, it is best for the ship to tack in succession, as, were they all to tack together, the van would be soon in with the land on one side, whil the stern ship, soon after the fleet had retacked, would be t near the land on the other side.

If he van and centre are to interchange, the van is to bea way a little, and then bring to, while the centre passes on t windward, edging a little to get ahead of the former van n the same line; the rear, coming on under an easy sail, edg away likewise, to gain the wake of the now centre squa ron.

I he van and rear are to interchange, the van and centre are bear away a little, and then bring to, so that the van may ear away a little more to the leeward than the centre. The ear stands on to gain the head of the line; and when abr st of the former van, the centre fills, and both standing n, form ahead of the now rear, by edging down till the are in a line with it.

I he centre and rear are to interchange, the van stands on der an easy sail, while the centre bears away a little, and rings to, and the rear at the same time carries a press of l to pass the centre to windward, and get into the wal of the van. The van and centre then edge away to gai the line with the now rear squadron, which then fills.

S veral evolutions are required while a fleet is in the fifth ord of sailing, and of these we shall notice some of the mo important.

hen the columns are to tack in succession, the ships of t e lee must tack first, as they have most distance to run; and when the leader of the centre comes abreast of the lea r to leeward, or at right angles with the close-hauled lin n the other tack on which the leader of the lee is now mo ng, she tacks, and is followed successively by the ships of r division. The weather column manœuvres in the san manner, paying the same regard to the centre. Here the weather column is still to windward, and should the col nns have closed too much, or be too far asunder, the ord may be recovered, either by the lee or windward col nn bearing away, so as to make an angle equal to that pro sed between any column, and a line joining the leader of t column and the sternmost ship of the next.

hen all the columns are to tack together, the sternmo ships put in stays together; and when in stays their sec ds ahead put down their helms, and so on through the whole fleet. Each column will then be in bow and qu er line.

hen the columns are to veer in succession, the leader of e lee column must steer four points free on the other tac followed by the ships of that division; and when she is ar of the sternmost ships of that division, she hauls up. Th same evolution is performed by the centre and weather shi successively standing on till they bring the point at wh h the lee column began to veer to bear in a right line to lee ard of them. They likewise successively spring their lu when the point at which the lee column hauled its wi l bears right to leeward.

ppose the fleet, when in the fifth order of sailing, is to tu to windward. Let the ships be so arranged that the le ers and corresponding ships may be in the direction of th wind. The van ships must tack together, and must be fo wed in succession, each by the remaining ships of the di sion, when they reach the wake of their leaders, or the sa e point when they tacked; so that there will always be th e ships in stays at once, till the whole fleet is on the ot r tack. The fleet then stands on to any proposed dista e, and retacks as before.

hen the weather and centre columns interchange, the weather and lee lie to, or only keep steerage way. The centre column tacks together, and forming a bow and quarter line, goes close hauled to gain the wake of the weather column; it then tacks together, and stands on, while the weather column bears away to its new station in the centre, and the lee column fills.

When the weather and lee columns are to interchange, the centre column must bring to, while the lee stands on under a press of sail; and when its sternmost ship can pass to windward of the van of the centre column, that is, when the centre ship of the lee is in a perpendicular line to the direction of the wind with the van of the centre column, the lee column then tacks together, and stands on close hauled till it comes in a line with the centre column, when it goes large two points to get into the situation which the weather column left, and then veers together, hauling the wind for the other tack. At the beginning of the evolution the weather column bears away together under little sail, and goes large six points on the other tack, to get into the wake of the centre column; it then hauls to the former tack, going two points large, till it comes abreast of the centre column, when it brings to, and waits for the now weather column.

Suppose the weather column is to pass to leeward. The weather column is to stand on under easy sail, while the centre and lee tack together, carrying a press of sail till they reach the wake of the weather column, when they retack, and crowd sail till they come up with it. The weather column, when the others have gained its wake, bears away two points to gain its station to leeward, when it brings to till the other columns, now the weather and centre, come up.

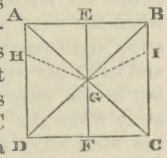
Suppose the lee column is to pass to windward. The weather and centre columns bring to, while the lee column carries sail and tacks in succession as soon as the leading ship can weather the headmost ship of the weather column; and when arrived on the line on which the weather column is formed, it retacks in succession, forms on the same line, and either brings to or stands on under easy sail. If it brings to, the other two columns bear away together two points, to put themselves abreast of the column now to windward; but if the now weather column stood on under an easy sail, they may bear away only one point, to gain their proper stations.

It is of the greatest importance that each ship of a fleet or squadron preserve her proper station and distance with respect to the rest. These may be regulated in two ways, either by observation with the quadrant, or by what is called the *naval square*. This square is usually constructed in the following manner.

Construction and use of the naval square.

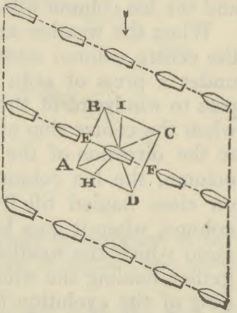
On some convenient place in the middle of the quarter-deck is described the square ABCD, fig. 29, having the sides AD and BC parallel to the keel of the ship. Through the centre G, the line EF is drawn parallel to AD or BC, and the diagonals AC and BD are drawn. The angles EGD, EGC are bisected by the straight lines GH, GI, and thus the naval square is completed. Now the angles FGD, FGC are = four points each, being each half a right angle, therefore the angles EGD, EGC, the complements of these angles, are each = twelve points, and consequently the angles EGH, EGI are each = six points, being each half of the last angles. Now, if a ship be running close hauled on the starboard tack, in the direction FE, the direction of the wind will be IG, and her close-hauled course on the other tack will be GC; but if she be running close hauled on the larboard tack in the same direction, her direction when close hauled on the starboard tack will be GD.

Fig. 29.



Now, to apply the naval square to the keeping of ships in their respective stations, suppose the fleet formed on the fifth order of sailing, close hauled, the corresponding ships of the columns coinciding with the direction of the wind, in order to run to windward with greater facility. The corresponding ships in the column must be kept in the direction of GH or GI, according to the direction of the wind and the tack they are on, while all the ships of the same column must be in the direction of EF. (See fig. 30.)

Fig. 30.



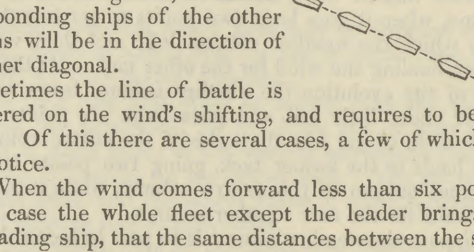
Again, suppose the ships arranged in three columns on one of the lines of bearing, and close hauled on the other tack. The ships of each column will be in the direction of one of the diagonals, while the corresponding ships of the other columns will be in the direction of the other diagonal.

To restore the order of battle, on shifts of the wind.

Sometimes the line of battle is disordered on the wind's shifting, and requires to be restored. Of this there are several cases, a few of which we shall notice.

1. When the wind comes forward less than six points. In this case the whole fleet except the leader brings to. The leading ship, that the same distances between the ships may be preserved on restoring the line, steers a course as *a b* (fig. 31), so as to be at right angles with the middle point between the former and present direction of the wind. His required course may be known by adding half the number of points the wind has shifted to eight points, and applying this sum to the former close-hauled course. When the leader has arrived at the new close-hauled line with respect to the second ship ahead, this ship immediately fills and bears away as many points as the leader; and when both these have reached the close-hauled line with respect to the third ship, she also fills and bears away; and thus with the rest in succession; and when they have got into the close-hauled line *b c* with the sternmost ship, they all haul their wind together, and the sternmost ship fills and stands on close hauled.

Fig. 31.



This may be expeditiously performed if the whole fleet fall off as soon as the wind shifts the same number of points, and the leader bear away eight points from the middle between the former and present directions of the wind; or when the wind shifts nearly six points, if the leader bear away eight points from the present direction of the wind, and hauls her wind as soon as the sternmost ship bears from her in the close-hauled line, while the second ship bears away when she reaches the wake of the leader, and hauls her wind when she has again gained his wake. The third, fourth, &c., ships bear away, and also haul their wind in succession, till the sternmost and the whole line be formed again.

2. Suppose the wind comes forward less than six points, and the order of battle is to be re-formed on the other tack. In this case all the ships are to veer round till their heads come to the requisite point with respect to their former course, when the rear ship, now become the van, hauls close by the wind, followed successively by the other ships. Should the wind come ahead more than six points, but less than twelve, the fleet is to manœuvre as before; but if it shift exactly twelve points ahead, the tack must be changed.

3. Lastly, suppose the wind to shift oft; if less than two points, the leader hauls her wind, while the fleet stands on as before, each successively hauling her wind as she gains the wake of her leader. If the tack is to be changed, the whole fleet tack together, and the sternmost ship, now the leader, hauls up, while the rest bear down and haul up in succession.

Should the wind change sixteen points, all the ships immediately brace about for the other tack, by which means the fleet will be going four points large; then the ships instantly tacking or veering together, the order of battle will be restored or formed again on the same tack as before the wind changed.

Having described and illustrated the principal evolutions which are performed by fleets or squadrons under ordinary circumstances, we are prepared to consider the nature and consequences of a naval engagement.

In forming a fleet for battle, it is proper to consider the size and number of the ships of which it is to consist, and the distance at which they are to be placed with respect to each other. In the present system of naval warfare, it is generally deemed of advantage to have the ships that are to form the principal line as large as possible; for though large ships are not so easily and expeditiously worked as those of a smaller size, they are most serviceable during the action, both as carrying a greater weight of metal, and as being less exposed to material injury, either from the enemy's shot or from the weather. In hoarding, too, a large ship must have greatly the superiority over a smaller, both from her greater height, and from the number of hands which she contains. With respect to the number of ships, it is of advantage that they be not too numerous, as, if the line be too extensive, the signals from the centre are with difficulty observed.

In arranging a fleet in line of battle, it is proper to regulate the distance so that the ships shall be sufficiently near to support each other, but not so close that a disabled ship may not readily be got out of the line without disturbing the rest of the fleet.

It has long been deemed a point of great consequence with the commander of a fleet to gain the weather gage, or to get to windward of the enemy, before coming to action. In deciding on the propriety of this, much will depend on the relative strength of each fleet, and on the state of the weather at the time. We shall state the advantages and disadvantages of the weather gage, as they are commonly laid down by writers on naval tactics, though we may observe by the way, that if a fleet be much superior to its opponent, it is seldom of consequence whether it engages to windward or to leeward.

A fleet to windward of the enemy is thought to possess the following advantages. It may approach the leeward fleet at pleasure, and can of course accelerate or delay the beginning of the engagement. If more numerous, it may send down a detachment on the rear of the enemy, and thus throw him into confusion. It may also readily send down fire-ships on the enemy's fleet, when thrown into confusion or disabled. It may board at any time, and is scarcely incommoded by the smoke of the enemy. The reverse of these circumstances of course acts against a leeward fleet.

The disadvantages of being to windward of the enemy respect chiefly the circumstances attending a retreat, should this be necessary. The windward fleet can seldom retire without passing through the enemy's line; and if, in attempting to retreat, the windward ships tack together, those of the leeward fleet may do the same, rake the weather ships in stays, and follow them on the other tack, having now the advantage of the wind. In stormy weather, the windward ships can seldom open their lower deck ports, and the lee guns are not easily managed after firing. Again, any disabled ships cannot easily quit the line without disordering the rest of the fleet, and exposing either that or themselves to be attacked by the enemy to leeward. A leeward fleet has the advantages of serving their lower-deck guns in all weathers; of being able to retreat at pleasure; of drawing off without difficulty their disabled ships; of forming with more readiness the order of retreat, or of continuing the action as long as convenient; of having it in their power, when superior in number, to double the enemy; and of cannonading with great effect the windward ships as they bear down for the attack.

As an engagement between two adverse ships is in some measure an epitome of an engagement between two fleets, we shall first briefly describe the former, as it takes place under ordinary circumstances, and shall then notice the usual manner of conducting a general engagement.

A naval engagement may be divided into three stages, the *preparation*, the *action*, and the *repair*.

When an enemy's ship heaves in sight, and it is thought advisable to bring her to an engagement, orders are first given to clear for action, which is begun by the boatswain and his mates piping up the hammocks, in order to clear the space between decks, for the more easy management of the guns, as well as to afford the men on the quarter-deck, &c., a better protection against the enemy's shot, the hammocks being stowed in the nettings above the gunwale and bulwark. After this the boatswain's mates go to work to secure the yards, which is done by fastening them with strong chains or ropes in addition to those by which they are suspended. They likewise get ready such materials as may be necessary for repairing the rigging, if it should be cut away or otherwise damaged, by the enemy's shot. In the mean time the carpenter and his mates prepare shot plugs and mauls, to stop any dangerous shot-holes that may be made in the hull near the surface of the water, and provide the necessary iron-work for refitting the chain-pumps, if their machinery should be injured during the engagement; while the gunner and his mates, and the quarter gunners, examine the guns to see that their charges are dry, and provide every thing that may be required for supplying the great guns and small arms with ammunition. The master and master's mates see that the sails are properly trimmed, according to the situation of the ship, and increase or reduce them as may be found necessary; and the lieutenants visit the different decks to see that all is clear, and to take care that the inferior officers do their duty.

When the hostile ships have approached within a proper distance of each other, the drums beat to arms; the boatswain and his mates pipe *all hands to quarters*. All the men who are to manage the great guns repair immediately to their respective stations. The crows, handspikes, rammers, sponges, powder-horns, matches, and train-tackles, are placed in order by the side of the guns; the hatches are immediately closed, to prevent sculkers from getting below; the marines are drawn up on the quarter-deck, &c., the lashings of the guns are cast loose, and the tompions withdrawn. The whole artillery above and below is run out at the ports, and levelled to the point-blank range, ready for firing.

When these necessary preparations are completed, and the officers and crew ready at their respective stations, and when the two ships are sufficiently near each other, in a proper relative situation for the shot to take full effect, the action commences with a vigorous cannonade from the great guns, accompanied by the whole efforts of the swivels and small arms. The firing is seldom performed in vollies, as that would shake the ship too much; but the guns are loaded and fired one after another, with as much despatch and as little confusion as possible, care being taken to fire only when each gun is properly directed to its object. During the firing, the lieutenants traverse the decks, to see that the battle is prosecuted with vivacity, and that the men do their duty; while the midshipmen second their injunctions and give the necessary assistance where required, at the guns committed to their charge. The youngest of these inferior officers are generally employed to carry orders from the captain. The gunners are all this time employed in the magazines, filling cartridges, which are carried along the decks in boxes by the boys of the ship. When the action has continued so long, or has produced such an effect, that one of the ships must yield or retreat, if the vanquished ship cannot get off, she acknowledges her inferiority by striking or hauling down her colours, when she is, as soon as possible, taken possession of by the victor, the commander of which sends a part of his own crew into the captured ship, and brings away most of her officers and men on board his own ship, as prisoners of war.

Repair.

The engagement being concluded, they begin to repair. The guns are secured by their breechings and tackles, with all convenient expedition. Whatever sails have been rendered unserviceable are unbent, and the wounded masts and yards struck upon deck, to be fished or replaced by others. The standing rigging is knotted, and the running rigging spliced where necessary. Proper sails are bent in the room of those which have been displaced as useless. The carpenter and his mates are employed in repairing the breaches made in the ship's hull, by shot-plugs, pieces of plank, and sheet-lead. The gunner and his assistants are busied in replenishing the allotted number of charged cartridges, to supply the place of those which have been expended, and in refitting whatever furniture of the guns may have been damaged by the action.

Engagement between two fleets.

A general engagement between two adverse fleets obviously involves a greater variety of circumstances, and requires greater judgment and more comprehensive skill in the commanding officer.

When the commander of a fleet has discovered an enemy's fleet, his principal object, if he be sufficiently strong, is to bring it to action as soon as possible. Every inferior consideration gives way to this important object, and all necessary preparations are immediately made to prepare for such an event. The state of the wind and situation of the enemy will in general regulate his conduct with regard to the disposition of his ships on that occasion. To facilitate the execution of the admiral's orders, the whole fleet is disposed in three squadrons, and each of these classed into three divisions, under the command of different officers. Before the action begins, the adverse fleets are drawn up in two lines, as formerly described. As soon as the admiral displays the signal for the line of battle, the several divisions separate from the columns in which they were disposed in the usual order in sailing, and every ship crowds sail to get into its station in the wake of the next ahead; and a proper distance from each other is regularly observed from the van to the rear. The admiral however occasionally contracts or extends his line, so as to regulate the length of his line by that of his adversary. This is more particularly necessary, to prevent his being doubled, by which his van and rear would be thrown into disorder. When the hostile fleets approach each other, the courses are commonly hauled upon the brails, and the top-gallant sails and stay-sails furled. The movement of each ship is regulated chiefly by the main and fore-top sails and the jib; the mizen-top sail being reserved to hasten or retard the course of the ship, and, by filling or backing, hoisting or lowering it, to determine her velocity. The signal for a general engagement is usually displayed when the fleets are sufficiently near each other to be within the range of point-blank shot, so that the guns may be levelled with some certainty of execution. After the battle has commenced, it is carried on much in the same manner as between two ships, except that each vessel of the fleet, besides attending to her own movements, has to observe the signals made by the commanding officer, and repeated by the frigates on the van and rear. The chief object of the admiral is to keep his line as complete as possible, by ordering ships from those in reserve to supply the place of such as may have been disabled, and to annoy the enemy as much as possible, both by strengthening the feeble parts of his own line, and, if circumstances admit of it, by sending down fire-ships upon that of the enemy. When the engagement draws near a close, either by the defeat of the enemy, or by the disabled state of either fleet, signals are made from the admiral to take possession of such of the enemy's ships as have struck, to tow his own disabled ships into a place of security, and either to chase the remainder of the enemy's squadron, or, if that be impracticable, to draw off his own ships to be refitted.

Such are the general incidents attending an engagement at sea, modified of course by numerous circumstances, of which a general description can convey no idea. There are however various movements and evolutions connected with a naval engagement, which it will be necessary for us to notice.

To dispute the weather-gage with an enemy.

Where the weather-gage is deemed of sufficient importance, it is often an object with two fleets to dispute it with each other. When the enemy is to windward, and it is wished to gain the weather-gage of him, the fleet to leeward should avoid extending itself the length of the enemy's line, in order to oblige them to edge down upon theirs, if they intend to attack them; which will be the means, if they still persist in doing so, of losing the advantage of the wind. It is impossible for a fleet to leeward to gain to windward, so long as the enemy keep the wind, unless a change happens in their favour; and therefore all that a fleet to leeward can do must be to wait with patience for such a change, of which they will undoubtedly avail themselves, as well as of any inadvertency the enemy may commit in the mean time. And as long as the fleet to leeward does not extend its line the length of the enemy's, it will be impossible for the latter to bring them to action without running the hazard, by bearing down, of losing the advantage of the wind, which both fleets will be so desirous of preserving. That an admiral may take advantage of such shifts of wind as occasionally happen, he must endeavour to get his ships into situations where these shifts most frequently take place. It is well known to experienced naval officers, that particular winds reign most on certain coasts, or off certain headlands. Here therefore the admiral should await the approach of the enemy; and though by this plan he may sometimes be unsuccessful, he will more frequently gain a material advantage. The disposition of projecting headlands, and the setting of tides and currents, often contribute materially towards gaining the wind of the enemy. The fleet to windward should keep that to leeward as much as possible abreast of it; and thus, unless the wind changes considerably, they will preserve the advantage which they have gained. They should also force them to keep their wind, unless they think it prudent not to engage, in which case it would be better to keep altogether out of sight.

To force the enemy to action.

When the enemy appears desirous of avoiding an action, there are various methods of attempting to force him to engage; as, first, when he has the weather-gage. In this case the lee fleet, which is desirous of bringing on an engagement, must keep always on the same tack with the enemy to windward, taking care to keep their own ships so exactly abreast of the enemy as to prevent losing sight of them; and hence be ready to take advantage of the first favourable shift of wind to make the attack. An alteration of the course may be best attempted in the night. The lee fleet must have frigates on the look-out, and these must continually give notice by signal of the manœuvres and course of the retreating fleet to windward. Thus the weather fleet is always exposed to pursuit, without being able to escape unseen; and hence must sooner or later be compelled to engage, unless they can get into some friendly port, or should be favoured by a gale of wind sufficient to disperse both fleets, and thus prevent the possibility of a general engagement.

Secondly, when the enemy is to leeward. If the lee fleet keep close to the wind in the order of battle, the fleet to windward is to stand on in the same manner till it be abreast of the enemy, ship to ship, and at the same time to bear away, and steer so as to bring their respective opponents on the same point of the compass with themselves. Thus the adverse fleets will be sufficiently near each other to begin the action, by each ship's presenting her bow to the ship abreast of her in the order of sailing, which may be easily changed for the order of battle, by all the ships hauling together close to the wind in the moment which precedes the action. If the fleet appear inclined to engage, it may bring to, to prevent losing time, and after this they will fill as soon as the action commences, because it is of advantage to a lee line to be advancing ahead. As the lee fleet fills and stands in close by the wind, the weather line should keep abreast before it bears away, to come within the requisite distance, that the van ship of the weather fleet may always keep to windward of the leading ship of the lee line, and be guarded against any shift of wind ahead.

If the lee fleet bear away four points to move their order of battle on the other tack, and avoid the action, filing off in succession in the wake of the van ship, the weather line, by bearing away all together eight points, cannot fail, as both fleets are supposed to sail equally, to pass through the middle of their line, and force them to fight with disadvantage, if their extent be double the distance between the two fleets. If the extent of the fleet be less than the above limitation, then the weather fleet will divide the lee fleet more unequally; and if the distance between the fleets be considerable, the weather fleet will be able to break through the line. If the lee fleet bear away four points all together, being of equal extent with the fleet to windward, and their distance from each other equal to that of the length of one of the lines, should the weather fleet bear away at the same time eight points, they will approach very near the sternmost of the retreating fleet, but they will not have it in their power to cut off any part of that fleet, even with an equality of sailing; so that the only advantage gained by this manœuvre will be an ability of attacking the rear, and bringing it to action.

If the van ship and the rest of the weather fleet had a sufficient velocity to keep the centre ship of the lee line on the same point of bearing, in that case the leading ship may break through the enemy's line about the middle ship of the centre division; for, supposing the fleets in the order of battle, on the starboard tack, steering east, with the wind at south-south-east, being at two leagues distance from each other, both the lines being four leagues in extent, then the lee line bearing away all together four points, will run north-east, while the fleet to windward, bearing away all together eight points, will steer north, the van ship of which will keep the centre division of the lee line in the point of bearing north-west. As she is supposed to be able to continue in this position, it follows that the van of the weather line must close the centre of the flying line to leeward after having run four leagues. The time and distance necessary to cut off a retreating fleet may always be known according to the last supposition. If the lee fleet should get on the other tack, and run large, still in the order of battle, they will be sooner forced to action by the weather fleet, who have only to bear away eight or nine points on the same tack, or run right before the wind.

As in forcing a fleet to action, there are two principal cases in which a fleet may avoid an action, where circumstances are not sufficiently favourable; first, when the enemy is to windward, and, secondly, when he is to leeward. In the former case, the lee fleet should form the order of ret at, if the enemy are in view, and run on the same tack as eir leading ship; but if he is still out of sight, and they ha received intelligence of his approach by their frigates on e look-out, they may bear away large, without confining hemselves to keep the wind directly off, unless when in e order of retreat. In the second case, it seldom happen that the weather fleet can be forced to an engagement, be use it can always stand on that tack which increases its stance from the enemy; that is, by standing on one tac while the enemy is on the other. The windward fleet mu not keep too near the enemy, and must take all possib means of avoiding being abreast of him.

is often of advantage to double the enemy; that is, to bri a part of the fleet round upon his van or rear, so as to pla him between two fires. This manœuvre also resolves itse into two principal cases; first, when the enemy is to wi ward; secondly, when he is to leeward. In the first cas the lee fleet that attempts to double the enemy should ext d itself abreast of him, so that its van or rear may exten beyond his line, in order to overreach him, by tacking in ccession, so that the extended part of the line may get up windward. If this manœuvre be properly executed, it l be impossible for the ships of the weather line long to intain their stations, for no vessel closely attacked by tw thers of equal force can long resist.

is of some consequence to determine whether the atten t to double should be made on the van or the rear of the nemy, as on the propriety of adopting the one or the oth of these measures may in a great measure depend the sue of the battle. In the present case, it is most easy to uble the van of the enemy, because, if they are engaged the ships abreast of them, those which are advanced ahe l will be able, by making all sail, to get in the perpendic ar to the direction of the wind with the van of the ene y, and to tack in succession to gain the wind of them on e other board, thus keeping them to leeward; and wh they are come sufficiently to windward, they are aga to go about, in order to keep the two headmost ships of e enemy's line continually under their fire. If there be o or three ships to tack in succession and gain the wi of the enemy, they may edge down on the van of the we her line at pleasure, keeping themselves a little to the wi ward of it; and as that van is already engaged by the oth ships abreast on the other side, she must necessarily soo be disabled. If they bear away they must drop upon th ne with which they are engaged to leeward, while the shi to windward still continue to cannonade them. If the attempt going about, in order to attack more closely th hips to windward, they will be raked, while in stays, by eir opponents to leeward and to windward, who enfilad g them with whole broadsides, which they cannot retur must complete their disorder. If they make sail, in or to frustrate the design of the ships inclined to double, th with which they are engaged abreast to leeward have onl to perform the same manœuvre, and keep them under the fire; while the others, after having harassed them as mu as possible, will do their best to perform the same manœ re on the succeeding ships.

ny of the ships in the van of the weather line are disabl in the masts or yards, they will drop astern, and run fou f the next succeeding ship, and these again on the ne astern. Thus the enemy's order of battle will be bro n, while on the other hand the lee line is preserved; an hose ships which have gained the wind of the enemy wil without engaging more ships than they can manage, con ibute to increase the confusion.

en the enemy is to leeward, and the weather fleet atten s to double, the ships of the weather line must extend the van beyond that of the enemy, and then veer in order to ing the headmost ships of the lee line between two fire It must not however be concealed, that it is much more dangerous to the ships engaged in this service to attempt doubling a fleet to leeward than to windward, as, if disabled, or separated too far from their own fleet, they cannot so easily extricate themselves and rejoin the fleet.

To avoid being doubled.

When one fleet attempts to double another, this latter will of course do all in their power to avoid the impending danger; and this they will the more readily do, according to their number or their situation. If the fleet thus threatened be to windward, one of the methods proposed to avoid being doubled, is to extend the line towards the point threatened, so as to leave a greater space between the ships; but in doing this there is a risk of having the line broken by the superior enemy. Another method suggested is, for the flag-ships of the windward fleet to oppose themselves to those of the lee line, which is supposed to render several of the enemy's ships in the intervals of little use; but one great inconvenience of this manœuvre is, that it leaves the van and rear most exposed to the enemy's fire, and that the rear division in particular is in great danger of being doubled. To remedy these defects, the largest ships should be placed in the van and rear of each division, and the fleet must regulate its sailing in such a manner that its rear shall never be astern of the rear of the enemy.

When the enemy is to leeward, the weather fleet is to keep astern of the enemy, so that the van of the weather fleet may be opposed to and attack the enemy's centre. Hence the enemy's van will become useless for some time; and should it attempt to tack and double on the weather fleet, much time will be lost in performing that evolution; and it also runs the risk of being separated by the calm which often happens in the course of an engagement, occasioned by the discharge of the guns. A considerable interval might also be left between the centre and the van, if necessary precautions be taken to prevent the van from being cut off.

Of chasing.

There are several circumstances of importance to be considered in the subject of chasing, *i. e.* when one ship or fleet pursues another, called the *chase*, either to bring her or them to action, or to oblige them to surrender.

In the case of single ships.

When a single ship chases another, it is to be presumed in general that one of them is the better sailer, though this is not always the case, and still by proper manœuvring the chasing ship, or *chaser*, may gain on the chase. In the following observations however we shall suppose the chaser to sail faster than the chase. The manœuvres of the chaser will depend on her being to windward or leeward of the chase.

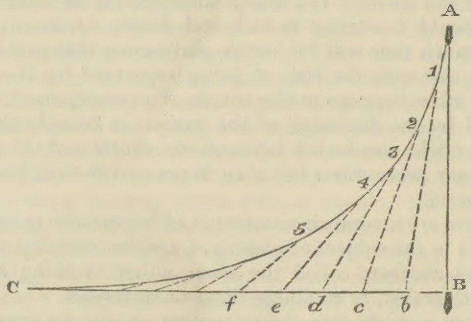
When the chase is to windward, it is evident, that as soon as she perceives a strange ship which she takes for an enemy, she will haul her wind, in order to prolong the chase, as otherwise her retreat would soon be cut off. The chaser then stands on nearly close hauled, till she has the chase on her beam: she then tacks, and stands on close hauled till the chase is again on her beam, and then retacks. In this manner she continues tacking every time she brings the chase perpendicular to her course on either board; and by thus manœuvring, it is certain that the chaser will, by the superiority only of her sailing, join the other in the shortest time. For since the chaser tacks always as soon as the chase is perpendicular to her course, she is then at the shortest distance possible on that board; and since the chaser is supposed to be the faster sailer, these shortest distances will decrease every time the chaser tacks. It is therefore of advantage to the chase to keep constantly on the same course, without losing her time in going about, as tacking cannot be so favourable to her as to her adversary, whose sailing is superior. If the captain of the chaser should so little understand his profession as to stand on a long way, and tack in the wake of the chase, the best thing she can do is to heave in stays, and pass to windward of him on the other tack, except she should find herself likely to gain advantage by going large; for if the chaser persists in tacking in the wake of the other ship, the pursuit will be very much prolonged.

When the chase is to leeward, the chaser is to steer that course by which she thinks she will gain most on the chase. If, after having run a short time, the chase is found to draw more aft, the chaser should then bear away a little more; but if the chase draw ahead, the chaser should haul up a little, and thus the course may be so regulated that the chase may always bear on the same point, and then the chaser will get up with the chase in the shortest time possible; for if any other course were steered, the chaser would either be too far ahead or too far astern, and hence the pursuit would be prolonged. The chase should run on that course which will carry her directly from the chaser, and should consider which is her best trim with respect to the wind, that she may move with the greatest possible rapidity from the chaser; for some ships have more advantage in going large, others with the wind right aft, and others when close hauled.

Curve of pursuit.

Another method has been proposed for chasing a ship to leeward; that is, by constantly steering directly for the chase. In this case, the tract described by the chaser is called the line or *curve of pursuit.* To illustrate this, let A (fig. 32) represent the chaser, and B the chase directly to leeward of her, and running with less velocity than the pursuer, in the direction BC, perpendicular to that of the wind. Now, to construct this curve, let B*b* be the distance run by the chase in any short interval of time; join A*b*, and make A1 equal the distance run by the chaser in the same time. Again, make *b c*, *c d*, *d e*, *e f*, &c. each equal to B*b*; join 1*c*, and make 1 2 = A 1; join 2*d*, and make 2 3 equal to A 1; proceed in like manner till the two distances carried forward meet as at C, and a curve described through the points A, 1, 2, 3, &c. will represent nearly the curve of pursuit; and the less the interval A1 is taken, the more accurately will the curve be formed. In this particular case, the length of the distance BC may be found as follows, provided the distance AB and the proportional velocities of the two ships be known.

Fig. 32.



Let the velocity of the chase be denoted by a fraction, that of the chaser being unity. Multiply the given distance AB by this fraction, and divide the product by the complement of the square of the same fraction, and the quotient will be the distance run by the chase B. Suppose AB, the distance of the chase directly to leeward of the chaser, be taken at twelve miles, and suppose the velocity of the chase three fourths of that of the chaser, what will be the distance run by the chase before she is overtaken? Now $\frac{12\times\frac{3}{4}}{1-\frac{3}{4}|^2}=\frac{9}{\frac{7}{16}}=9\times\frac{16}{7}=20\frac{4}{7}$ miles; and since the velocity of the chaser to that of the chase is as 4 to 3, hence the distance run by the chaser will be $= 20\frac{2}{7}\times\frac{3}{4}=27\frac{3}{7}$ miles. As the chaser alters her course at every point, and probably sails better with the wind in one direction with respect to her course than when the wind is in another direction, her velocity will be different at different points of the course. Thus, suppose her to sail faster when the wind is on the quarter, her velocity will constantly increase to a certain point, and will then diminish. Hence in real practice the curve of pursuit will not be exactly what is laid down in the above problem, and of course the measure of BC will differ a little from what we have there laid down. See RESISTANCE OF FLUIDS, and SEAMANSHIP.

If the whole fleet is to give chase, the admiral will make the proper signal, and then each ship will instantly make all the sail possible. If the retreating fleet is not much inferior to the other, a few of the fastest sailing vessels only are to be detached from the superior fleet, in order to pick up any stragglers, or those ships which may have fallen astern; and the remaining part of the fleet will keep in the same line or order of sailing as the retreating fleet, so that they may, if possible, force them to action. But if the retreating fleet is much inferior, the admiral of the superior fleet will make the signal for a general chase, and then each ship will immediately crowd all the sail possible after the retreating fleet; or, if the chase be still less numerous, the admiral will detach one of the squadrons of his fleet, by hoisting the proper signal for that purpose, and he will follow with the remainder of the fleet. The squadron that chases should be very careful not to engage too far in the chase, for fear of being overpowered; but at the same time to endeavour to satisfy themselves with regard to the object of their chase. They must pay great attention to the admiral's signals at all times; and in order to prevent separation, they should collect themselves before night, especially if there be any appearance of foggy weather coming on, and endeavour to join the fleet again. The ships are diligently to observe when the admiral makes the signal to give over chase; and each regarding the admiral's ship as a fixed point, is to work back into her station, so as to form the order of line again as quickly as the nature of the chase and the distance will permit.

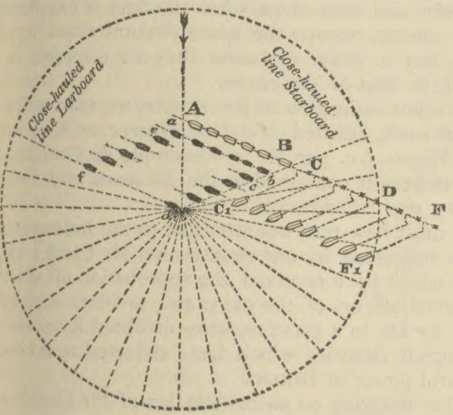
When a fleet is obliged to run from an enemy who is in sight, it is usual to draw up the ships in that form or order called the *order of retreat;* and the admiral, when hard pursued, without any probability of escaping, ought, if practicable, to run his ships ashore, rather than suffer them to be taken afloat, and thereby give additional strength to the enemy. In short, nothing should be neglected that may contribute to the preservation of his fleet, or prevent any part of it from falling into the hands of the conqueror.

We have now gone through the principal evolutions of fleets and squadrons nearly as they are described in the "Elements of Rigging, Seamanship, and Naval Tactics," and other approved publications on similar subjects. We have indeed omitted the method of forcing an enemy's line, and of avoiding being forced, because the former will be readily understood from what we have to add on the improved method of tactics of M. Grenier, and Mr Clerk of Eldin.

Various defects have been observed in the tactics usually employed at sea, especially in a line of battle, and in the mode of bringing an enemy to action. The usual order of battle first introduced by the duke of York, afterwards James II. of England, is defective from its length. Its great extent makes it difficult for the admiral to judge what orders are proper to be issued to the ships stationed at the extremities, while his signals, however distinctly made, are liable to be mistaken by the commanders of these ships. Besides, the extremities of a long line, especially if it be to leeward, are necessarily defenceless, as the enemy may th ow himself with a superior force on the van or rear, and c either of these off before it can be properly supported b the other squadrons. Viscount de Grenier, who was, w believe, one of the first to notice these defects, proposed t emedy them by introducing a new order of battle.

he leading principles of De Grenier's tactics are founded on the following considerations. It is evident that each sh of a fleet must at all times occupy the centre of a certa horizon. This horizon De Grenier divides into two unqual parts, calling the greater the *direct and graduated sp e*, and the less the *indirect, crossed, and ungraduated sp e*. The reason of these appellations is, that on the gr ter segment of the horizontal circle there are twenty diffe nt points, which may be marked by degrees from one of th close-hauled lines to the other, and to which a ship ma sail from the centre by so many direct courses without ta ing; whereas from the other twelve points, including th from which the wind blows, she cannot arrive but by ste ing cross courses, which must necessarily delay her pr ress. Suppose now a fleet to leeward, so disposed that on a part of it can fight with another equally numerous, an ranged to windward in a single line, and let the lee fle be ranged on three sides of a lozenge *a b, c d, e f*.

Fig. 33.



Th squadron *a b*, which is most to windward, being drawn up line of battle, cannot be fought but by an equal number AB, CD, EF. All the rest of that fleet therefore must ren n inactive, unless the ships which are not engaged sho d try to pass to leeward of the fleet *a b, c d, e f*. But sho d the ships of the weather fleet, which are placed betwe B and F, bear away, as they appear in the figure, betwe C *i* and F *i*, the ships between A and B, which are fig ng to windward, cannot bear away with them. Suppos now that the ships between C *i* and F *i* have passed to eward, the squadrons *c d, e f*, which are ranged accor ng to De Grenier's system, and have not yet been engag l, should come to windward, and join with their friends a gainst that squadron of the enemy AB which is still to ndward and engaged; it is almost impossible but that the quadron AB must be destroyed by so great a superiori before it could receive assistance from the ships to lee rd between C *i* and F *i*.

I Grenier propos only three ord s of sailing; one when a fleet is t pass a strait; a se ond, when it stee in open sea, on t look-out for an emy, or with a v w to avoid him; and a third, when on an extensive cruise, disposed so that it cannot be easily surprised or broken. Of these three orders, only the second and third differ from the usual orders of sailing. The former of these is represented by fig. 34, where the columns, *a b, c d, e f*, are disposed on three sides of a regular lozenge, on the two close-hauled lines. The ships of the two divisions *c d, e f*, sometimes to windward, as in fig. 35, and sometimes to leeward as in fig. 34, of the third division *a b*, are to be formed on two parallels of one of the close-hauled lines in the wakes of their respective headmost ships; while the third division *a b* is to be ranged ahead or astern of the others on the other close-hauled line, steering chequerwise the same course as the other divisions.

Fig. 34.

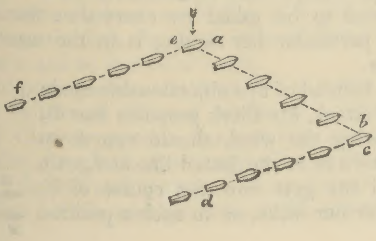


Fig. 35.

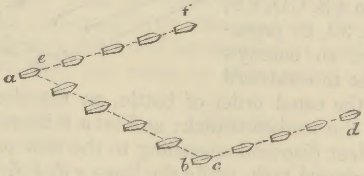
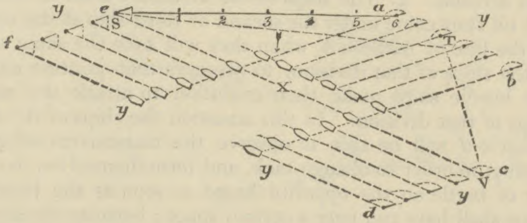


When *a b* is to windward of *c d* and *e f* (fig. 34), De Grenier calls that the *windward primitive order of sailing*; and when to leeward (fig 35), the fleet is said to be in the *leeward primitive order of sailing*. These are the two principal positions in almost every case, and, with very little variety, may become the order of battle, of chasing, &c.

Fig. 36.



His third order is illustrated by fig. 36, where the divisions *a b* and *e f* are supposed at the distance of about six leagues from each other; *c d* and *e f* resting on the extremities of the base of a triangle STV, while the centre ship of the division *a b* rests on its summit T: none of the divisions could be cut off by an enemy, however formidable, seen from its centre ship at the distance of six leagues. For if, on the proper signal, the division *a b* should steer from T toward X, on the course opposite to the close-hauled line it steered before, and the two divisions *c d* and *e f* steer from V and S towards X likewise, it is plain that each of these divisions would have only three leagues to run in order to join the other two, while the enemy, which was first perceived at the distance of six leagues, must run nine before he can come up with the nearest of these squadrons.

Fig. 37.

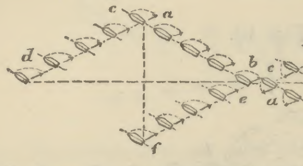


Fig. 38.

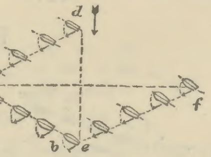


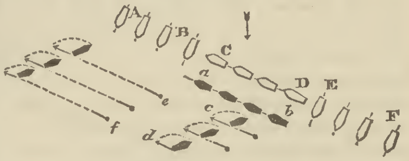
His order of battle.

To form De Grenier's order of battle, represented in fig. 37 and 38, it will be sufficient for the ships of the three divisions ranged in the windward primitive order of sailing, to heave in stays all together, and get on the other tack on the opposite line of bearing (fig. 37); or for the ships in the leeward primitive order at once to haul the wind on the same tack as they steer; and they will find themselves in order of battle, fig. 38. When the two columns *c d* and *e f* are to leeward of the third division *a b*, ranged in order of

Warlike Operations at Sea.

battle, this is called the *natural order of battle;* and when *c d* and *e f* are to windward of *a b*, this is called the *inverted order of battle.* The former of these is calculated for a fleet combating to leeward, and the latter for a fleet which must fight to windward.

Fig. 39.



To explain the advantages of these dispositions, let us suppose the line AB, CD, EF, fig. 39, to represent an enemy's fleet to windward in the usual order of battle, on the close-hauled line, and on the starboard tack; and let *a b* be one of the divisions of a fleet disposed according to the now natural order, on the starboard tack, while the lines *c d*, *e f*, represent the other two divisions standing on chequerwise on the same tack, but formed on the opposite close-hauled line. When the enemy comes to attack this latter fleet on a supposition that it is inferior to their own, their divisions AB and EF, in order to attack the ships *a* or *b*, must bear away. Now, to prevent the attack, each of the divisions *c d*, *e f*, must make the following evolutions, according to their respective situations and the manœuvres of the enemy. 1. The ships of the division *a b* are to slacken as much as possible their headway, and form a very close line, till the enemy makes a movement to attack the headmost or sternmost ship of that division. 2. The ships of the division *c d* are to make sail till they come under the second or third ship of the rear of the line of battle *a b*, when they will take the same sail as the ships of that division, to preserve that position until the hostile ships make their evolution to attack the rear ships of that division. In this situation the ships of the division *c d* will be able to observe the manœuvres of the enemy, in order to change tack, and form themselves in order of battle on the opposite board as soon as the hostile ships shall have run over a certain space; because the ships of the division *c d*, steering afterwards close hauled in the wake of the sternmost ship of the division *a b*, will be able to cover the rear ships of that division, and get the weather-gage of the hostile divisions which are bearing away; rake their ships; run alongside of them; double their rear-guard, and put it between two fires, if those hostile ships are following in the wake of each other; divide it if they bear away chequerwise; or gain to windward, and put between two fires the enemy's division CD, while engaged with the division *a b*. 3. The division *e f* may abandon their post, and run chequerwise under a press of sail, as soon as the enemy falls ahead of *a b;* that if the enemy's division AB attempts to fall on *e f*, or on the van of *a b*, they may, by going about, steer in order of battle close hauled on the opposite line, and cover the ship *a*, double the hostile division CD ahead, or divide AB, which is running chequerwise on the opposite tack.

Fig. 40.

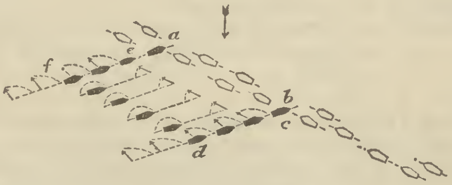


Fig. 40 marks another method of manœuvring by the divisions *c d*, *e f*, when the enemy's ships are arranged in a single line not well formed.

Figs. 41 and 42 illustrate De Grenier's method of placing the admiral's ship, and the frigates and transports attached to a fleet. A, fig. 41, is the admiral placed ahead of the fleet, at a short distance from the headmost of the second division, and in the same direction of the wind as the headmost ship of the first division; *f f* are two frigates observing the same rule and position with respect to the van ship of the third, and rear of the first division. When the fleet is in order of battle, as in fig. 42, the admiral's ship A is in the centre of the lozenge, and two of the frigates, *f f*, are on the fourth side of the lozenge. The transports and store-ships, when the fleet is in order of sailing or convoy, occupy the space circumscribed by the lozenge, but in order of battle they are disposed in a line opposite to that of the enemy.

Fig. 41.

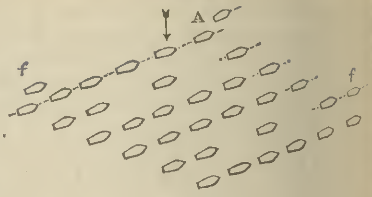

Fig. 42.

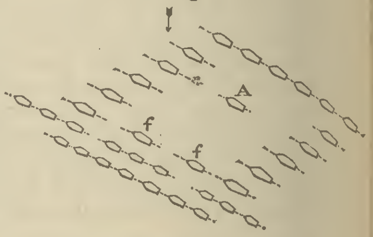

For a full exposition of this system, we must refer to the original work, entitled *L'Art de Guerre en Mer, ou Tactique Navale*, &c. par M. le Viscompte de Grenier, or the extracts from it contained in the *Elements and Practice of Rigging and Seamanship.*

We must now turn our attention to the improvements in tactics suggested by our countryman Mr Clerk; improvements which have received the approbation of several distinguished officers of the navy, and to hints derived from which we are in a great measure indebted for some of the most signal victories which have reflected new honour on the naval power of Britain.

Before entering on an explanation of Mr Clerk's tactics, we must briefly state his objections to the usual method of bringing ships to action, by the weather ship or fleet steering directly down upon the enemy. By doing this, the enemy to leeward often has an opportunity of completely disabling the ships making the attack, as the former can use all their guns on one side, while the latter can only use their bow chases. Suppose B, fig. 43, to represent a ship of eighty guns to windward, in sight of an enemy's ship of equal force F to leeward. Now, if B bears down directly upon F, the latter, by lying to, as in fig. 44, will present a broadside of forty guns, all bearing for a considerable time on B, while the latter coming down headwise, can only bring the two light guns of her forecastle to bear on F, not to mention that F, by lying broadside to, will have her masts and rigging little exposed to the enemy's shot, while B, standing head on, is exposed to be raked by every shot from F, and in particular her rigging is in the utmost danger.

Fig. 43.

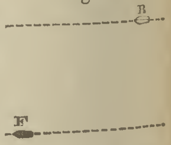

Fig. 44.

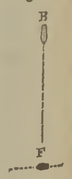
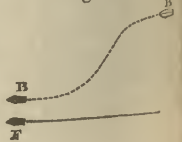


Instead of this objectionable mode of attack, Mr Clerk proposes that B, having the wind, should run down astern as in the dotted line at fig. 45, till she gets into the course of F, near her wake, or in such a position

Fig. 45.



Warlike Operations at Sea.

will bring her parallel to s course, and within a pror distance, when she can n up close alongside of F, d engage on equal terms; that she should shoot aad, then veer, and run wn on the weather bow of as in fig. 46, till she can force the chase to bear away to ward, keeping close by her, on equal terms, taking care both cases not to put it in the power of F to bring her oadside to bear on her without retaliation.

Fig. 46.

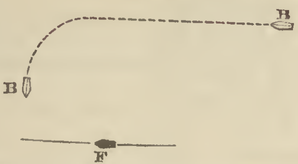


Fig. 47 is employed by Mr Clerk to illus- te the different procedure of a French and British man of war in firing, the former at t rigging, and the latter at the hull of the emy, with their effects. Let F represent a lge ship desirous of avoiding a close engage- nt, but lying to, to receive with advantage a enemy's ship B, of equal force. Suppose tt F, by firing at the rigging of B, may have cried away some of the principal stays, seve- r of the windward shrouds, a fore-topmast, or other rig- g g of less consequence, without having wounded a single n n; and suppose a second ship, consort to F, receiving an e my's ship like B, but firing only at her hull, so as to kill t ty or forty men, without damaging her rigging. Now, w n F and her consort wish to avoid a close engagement, it evident that the ship B which has lost part of her rig- g g, is much more disabled from coming to close action than h consort whose rigging is entire, though she may have l a great number of her men.

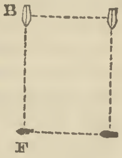
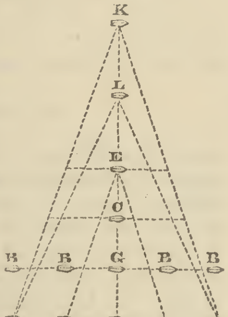
Fig. 47.



By the scheme at fig. 48, it is i nded to illustrate the impossibi- li of one ship being exposed to t fire of many ships at one time. L I, H, F, H, I, represent five s s in line of battle ahead, about a able's length, or 240 yards, a- s der, and suppose the length of e h ship to be forty yards, so that t whole space between the head o one ship and the head of that n t adjacent equals 280 yards. L the perpendicular line FK, ex- t ding from the beam of F six c les' lengths, or 1440 yards, be d ded into six equal parts. It is e ent that any ship stationed at E in the line FK, 720 y s distant, cannot long be exposed to the fire of more t the centre ship F of this squadron. For if we suppose t H and K, ahead and astern of F, can bring their b dsides to bear on E, by putting themselves in positions f hat purpose, they will not only disorder their own line, b one will leave her head and the other her stern exposed t raking fire from the opposite ships BB in the enemy's li If B can suffer little from the two ships H, H, at the di nce of 720 yards, it is evident that she will suffer still le from these ships as she approaches nearer the enemy's li Again, if instead of a cable's length asunder, we sup- p the ships I, F, I, two cables' length asunder, to bear o he ship B, it is evident from the figure that in this ca B will not be more exposed to the fire of I and I at th istance of 1440 yards, than she was to that of H and H at lf that distance; and so in similar cases.

Fig. 48.



explaining the principles on which we are to judge of th advantages or defects of different modes of bringing sh s to action, Mr Clerk supposes a fleet of ten, twenty, or ore ships, of eighty guns each, drawn up in line of battle to eward, as at F, fig. 49, and lying to with an intention of voiding an action; while another fleet, as B, of equal number and force, also drawn up in line of battle three or four miles to windward, wishes to make an attack, and come to close quarters on equal terms. The fleets being thus disposed, should the fleet at B attempt running down to attack the fleet at F, each ship standing head on to the opposite ship in the leeward line, it is to be expected, from what we have already stated, that the attacking ships will be disabled at least in their rigging before they can come to close action; but suppose that the commander of the weather fleet, though his ships have been disabled in their rigging during their course *a a a* to leeward, fig. 50, has made them bring to at a great distance, but sufficiently near to injure F, this latter fleet, which has been endeavouring to avoid an action, will now bear away with little injury to a new station, as G, and there remain out of the reach of B's shot, and this fleet must repair its rigging before it can make another attack.

Fig. 49.

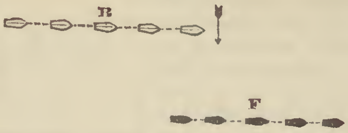


Fig. 50.

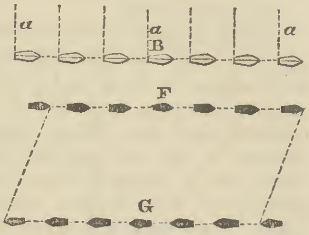
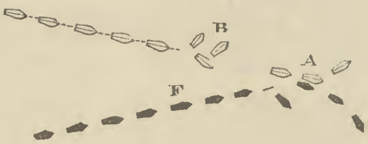


Again, suppose that the fleet B, instead of standing head on, were to run down in an angular course, as in fig. 51. It is plain that if any ship in this angular line should be crippled, her defect in sailing will occasion a confusion of several of the other ships in that line. It may be said that the stoppage of one ship ahead will not necessarily produce a stoppage of every ship astern of her, because they may run to leeward of the disabled ship; but we must observe that by this time the ships ahead in the van A may be engaged, and consequently, not having much headway, are nearly stationary, so that each ship astern, in attempting to bear down as at D, D, may be confined to a certain course, and must run the risk of being raked in coming down before the wind, and consequently of being disabled before coming up with the enemy.

Fig. 51.



Thirdly, the van of the fleet B having attained their station at A, abreast of the van of F, fig. 52, and having begun the action, the van ships of F, with a view to retreat, may throw in a broadside on the van of B, and then bear away in succession, as at H, followed by the rest of the fleet F, which, after exchanging broadsides with the van of B, may draw up in a new line two or three miles to leeward at I I, fig. 53.

Fig. 52.

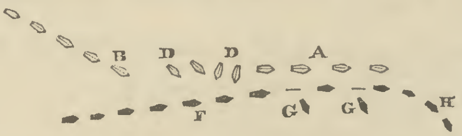


Fig. 53.

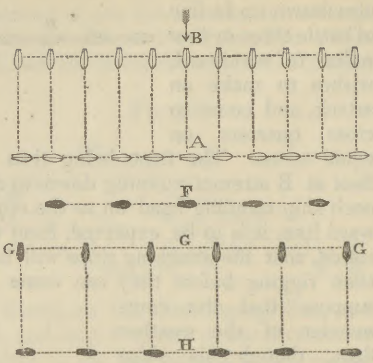
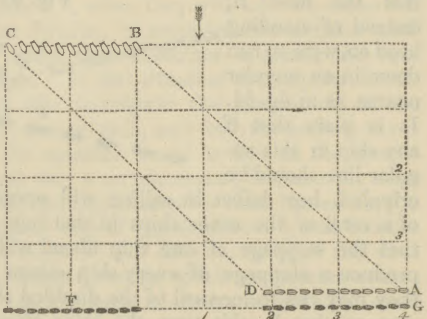
Suppose, again, for further illustration, that B, fig. 54, represents a fleet putting before the wind, each ship intending, when brought to at a determined distance at A, to take up her particular antagonist in the line of the enemy F to leeward; and let F be supposed at rest, without any motion ahead. It is easy to conceive, that while the alternate ships of F's line, under cover of the smoke, withdraw from battle to GGG, the intermediate ships left behind them in the line will be sufficient to amuse even the whole of B's fleet, till the ships G shall form a new line H as a support from the leeward. In such case B, after being disabled, and not having foreseen the manœuvre, will neither be able to prevent the intermediate ships with which he is engaged from bearing away to join their friends, nor, were he able, would it be advisable to follow them; for the same manœuvre, with equal success, can again and again be repeated.

Fig. 54.



To explain the relative motion of these two fleets, let F, fig. 55, represent a fleet of twelve ships in line of battle, a cable's length asunder, and suppose the length of each ship from the end of the jib-boom to the stern to be 36$\frac{2}{3}$ fathoms. The whole fleet will occupy a space of two English miles; and if it be supposed to sail in the direction FG, at the rate of four knots an hour, it will in an hour have moved to G, four miles from its former position.

Fig. 55.



Now let there be an opposite fleet B, also twelve ships, situated four miles to windward, and let the point A be a quarter of a mile right to windward of the point G. Then, if B, by bearing away in the direction BA, gain the point A at the same time that the leeward fleet F has arrived at G, B will have moved nearly at the rate of 5$\frac{1}{2}$ miles an hour, and the angle contained between the direction of its line of bearing and its present course will be nearly four points.

Secondly, in fig. 56, if F, by carrying more sail, move at the rate of six miles an hour from F to G, then B, with a more slanting course, will have more difficulty in keeping the line abreast while coming down to the attack, owing to the additional obstruction which will attend each succeeding ship in such a slanting course. Again, if the leeward fleet shall lie up one point higher, as FG, fig. 57, the rears of the two fleets will be removed to a much greater distance, and the van A must be sooner up with the enemy's van, and of course so much farther from support, while F, bringing up his ships in succession, may disable the van of A, and afterwards bear away at pleasure with little injury, as at H. Now B being supposed disabled, and having his rear D distracted, will be unable to prevent F from escaping.

Fig. 56.

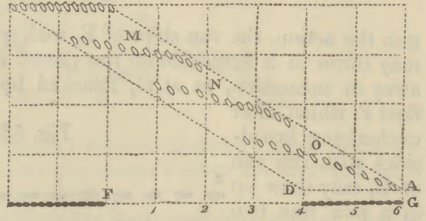


Fig. 57.

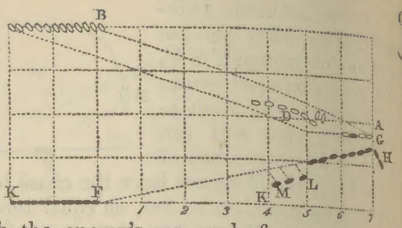

From these considerations, it appears that a fleet to windward, by extending its line of battle with a view to stop and attack the whole line of an enemy's fleet to leeward, must labour under considerable disadvantages, and will scarcely succeed in the attempt.

On these principles Mr Clerk explains the reason why the French fleets so repeatedly escaped from the British without any serious defeat or loss, viz. by avoiding a general engagement, and disabling the British van as it bore down to attack them. He therefore recommends a different mode of attack from the windward, which we shall proceed to illustrate by proper diagrams.

Let F (fig. 58) represent a fleet in line of battle, under easy sail, willing to avoid an action, but ready to receive an attack, in the usual way, from another fleet B, three or four miles to windward, arranged in three columns. How shall B make the attack on F, so as, without aiming at the improbable advantage of taking or destroying the greater part of this fleet, they may secure three or four of the sternmost ships? Mr Clerk advises that a sufficient strength be detached to secure these ships, while the admiral keeps aloof with the rest of his fleet, disposed as in the figure, ready to make the necessary observations, and give the requisite support to the detached ships. If F continues to avoid an action by standing on in line, the detachment, coming into the position BA, will secure the three ships at I; and if the headmost ships of F were to tack, and be followed by the rest in succession, as at fig. 59, not only the three ships at I will be left at the mercy of the ships detached from B, but two more, as G, will be exposed to an attack from another squadron of B at C. If all the ships of F tack together, as in fig. 60, the delay, and probably the confusion,

Fig. 58.

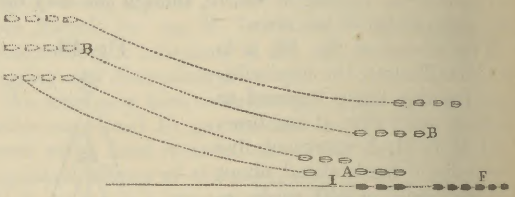

Fig. 59.

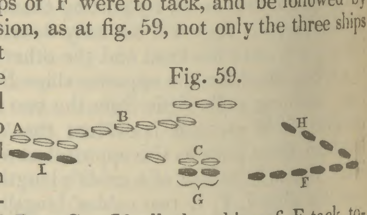

Fig. 60.

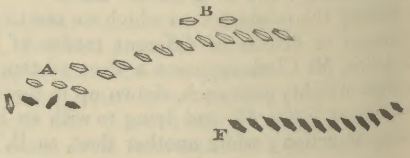

Warlike Operations at Sea.

consequent on this manœuvre, will still more endanger the sternmost ships, or will bring on a general and close action. Again, if F attempts to haul off, beginning with his sternmost ship G, and then runs to leeward, as at fig. 61, he will expose his ships to a raking fire from B, and still endanger his sternmost ships, by getting too far to leeward for their support; or if the headmost ships at H, fig. 62, veer first, to be followed by the rest astern, the danger would be still greater. Thus it appears that, in every assignable case, a fleet to leeward, avoiding an attack from an equal or superior to windward, as here advised, by preserving the line will risk the loss of three or more of their sternmost ships.

Fig. 61.

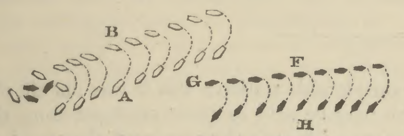

Fig. 62.

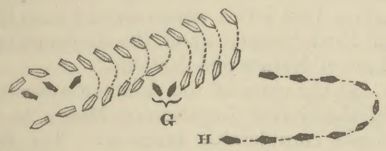

Now, let us suppose that F, while standing on a line on the larboard tack, when threatened with an attack on his rear from B, veers and passes on opposite tacks to leeward (see fig. 63). The consequence of this will be, that his headmost ships will be forced to leeward by B, and compelled to engage under disadvantageous circumstances; and the disadvantage to F will be much the same, whether he again veers and resumes his former position, as at G, fig. 64, or stands on before the wind, as at P, fig. 65.

Fig. 63.

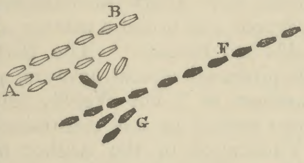

Fig. 64.

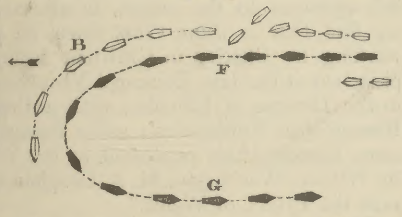

Fig. 65.

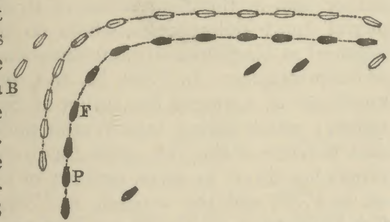

We have hitherto supposed that the wind has been fixed in one point; but let us suppose it to shift, and let us inquire what will be the effect of such a circumstance on the two lines F and B. While the fleets are in the former position, F in line, and B in four divisions, B, B, B, A, steering east, with the wind at north, fig. 66, let the wind shift to the west. The only consequence of this will be, that F will be thrown still farther to leeward, to its greater disadvantage. But let the wind shift to east, so as to be ahead, as in figs. 67 and 68; still, if the admiral of B manages properly, and carefully watches the motions of F, this change will produce no advantage to the latter. For B has nothing to do but veer as the wind comes round, so as to bring his ships to windward of the three sternmost ships of F, and to leeward of the rest of his line, so as to cut off the three sternmost ships.

Fig. 66.

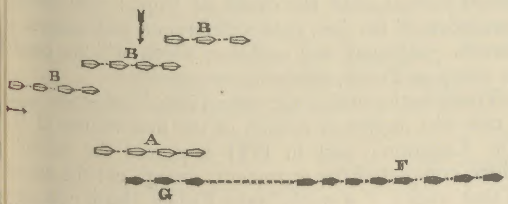

Fig. 67.

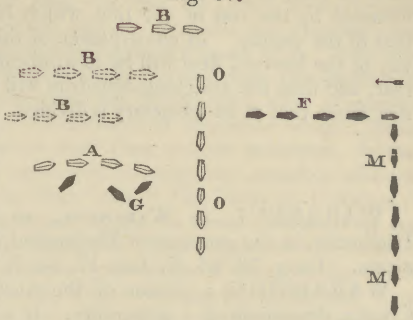

Fig. 68.

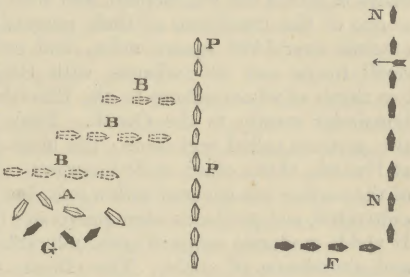
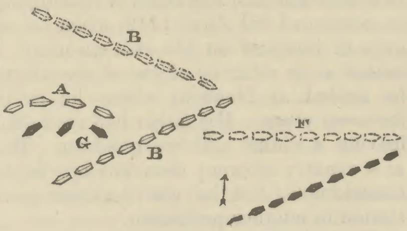


If the wind should be supposed to veer from point to point all round the compass, so that the fleet F, maintaining the weather-gage of B, shall make a circuit round B to leeward; still, if B act cautiously, F will lose the three threatened ships.

Lastly, suppose the wind should instantly shift to a point opposite to what it was at the commencement of the attack, as from north to south. Before it can be ascertained whether such a change will be to the advantage or disadvantage of F, the relative situations of the two fleets must be considered. Suppose that the van and centre be separated at some distance from his rear, and that in consequence this fleet shall have taken such a position as is shown at fig. 69. Though in this case he will have got to windward, his three ships can never be regained or preserved from the attack of B. The most favourable situation for F would be when the fleets were in the position denoted by fig. 66, as then he could not only support his three ships with advantage, but even threaten and cut off a part of B's detachment. In attempting this, however, he incurs the risk of coming to a close engagement, which we have supposed him to be sedulously avoiding.

Fig. 69.



From the leeward.

Besides this method of attack from the windward by detachments from the main fleet, Mr Clerk shows how a successful attack may be made by a fleet *to leeward*, by its breaking the enemy's line, and this either near the rear, near the centre, or not far from the van, of which cases the two former will be most likely to prove successful. The enemy's line can only be cut when the two hostile fleets veer on opposite tacks. The most simple method of effecting this is for the van ship of the attacking squadron, instead of ranging parallel to that of the enemy, and to leeward of him, to pass through the first interval that offers, followed by the rest of the line, which is thus led across that of the enemy. In consequence of this manœuvre, the van of the leeward fleet will be to windward of the enemy's rear, and thus the attacking squadron will have its line entire, while that of its adversary is divided. Again, the ships of the rear division, having their progress obstructed, will probably crowd on each other, get into confusion, and be driven to leeward. We cannot detail the different cases mentioned by Mr Clerk; but for these, and many other valuable suggestions on the subject, we must refer to his well-known and ingenious Essay on Naval Tactics.

WARANKUL, or WARANGOL, an ancient city of Hindustan, in the province of Hyderabad, belonging to the nizam. Long. 79. 34. E. Lat. 17. 54. N.

WARARSDIN, a portion of the Austrian province of Croatia, denominated a generality. It is on the frontier towards Turkey, and peopled with military colonists, the males of which are regimented, and held ready for service as one of the conditions of their possessing the land. It extends over 1470 square miles, and comprehends three small towns and 306 villages, with 108,500 inhabitants, two thirds of whom adhere to the Romish church, and the remainder mostly to the Greek. They are divided into two portions called regiments; the head-quarters of one is at Ivanich, of the other at St George's. Nearly two fifths of the surface are covered with woods, but the remainder is cultivated, and produces more provender than is consumed. It yields moderate crops of corn, tolerable wine, some silk, and abundance of cattle. The climate is mild, and the district is watered by the Drave and its numerous tributary streams. There are no manufactures, but these are purchased with the surplus of the products of the soil. The principal town, Ivanich, has only 650 inhabitants. Long. 16. 25. 5. E. Lat. 45. 42. 9. N.

WARBURTON, WILLIAM, a learned and distinguished writer, descended from an ancient family in Cheshire, was the eldest son of George Warburton, an attorney at Newark in the county of Nottingham, and was born on the 24th of December 1698. He was first sent to school there under a Mr Twells, but had the chief part of his education at Okeham in Rutlandshire, where he continued till the beginning of the year 1714. He then returned to his native town, and for a short time was under the care of his cousin William Warburton, who had recently been appointed head master of Newark school. Being destined for the profession which had been followed by his father and grandfather, he was placed as a clerk to Mr Kirke, an attorney of East Markham in Nottinghamshire, with whom he continued till April 1719, when he was qualified to engage in business on his own account. Having been admitted as an attorney of one of the courts at Westminster, he settled at Newark, where he continued to practise for some years. His father had died about the year 1706, leaving a widow and five children. Warburton's success as a country attorney does not appear to have been very considerable, but he was destined to reach an eminent station in another profession.

He had always expressed a strong inclination to take orders; and the love of letters, which tended to retard rather than forward his progress in the profession chosen for him by his friends, growing every day stronger in him, it was deemed expedient to give way to that inclination. He therefore devoted himself to the studies necessary to fit him for the church, and at length in 1723 he was ordained deacon, and priest in 1727. In 1728 he was presented by Sir Robert Sutton to the rectory of Brand-Broughton, in the diocese of Lincoln, where he spent the greater part of his life, and composed all the great works which will carry his fame down to posterity. During the same year he was put upon the king's list of Masters of Arts, created on his majesty's visit to the university of Cambridge. He had already published some juvenile performances, which displayed genius and reading, and attracted considerable notice; but it was not till the year 1736 that he may be said to have emerged from the obscurity of a private life into the notice of the world. The first publication which rendered him famous now appeared, under the title of "The Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test Law; demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations."

At the close of the Alliance was announced the scheme of the Divine Legation of Moses, in which he had then made considerable progress. The first volume of this work was published in January 1737–8, under the title of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the Omission of the Doctrine of a future State of Rewards and Punishments in the Jewish Dispensation, in six books." The arrogance of the author was at least equal to his learning; and this work, as he afterwards observed, was fallen upon in so outrageous and brutal a manner as had been scarcely pardonable had it been "The Divine Legation of Mahomet." It produced several answers, and so much abuse from the authors of "The Weekly Miscellany," that in less than two months he was constrained to defend himself, in "A Vindication of the Author of the Divine Legation of Moses, from the Aspersions of the Country Clergyman's Letter in the Weekly Miscellany of February 24, 1737–8." His extraordinary merit had attracted the notice of the heir-apparent to the crown, in whose immediate service we find him in June 1738, when he published "Faith working by Charity to Christian Edification, a Sermon, preached at the last Episcopal Visitation for Confirmation in the Diocese of Lincoln; with a Preface, showing the Reason of its Publication; and a Postscript, occasioned by some Letters lately published in the Weekly Miscellany; by William Warburton, M. A. Chaplain to his Royal Highness the Prince of Wales."

The "Essay on Man" had now been published some years; and it has sometimes been supposed that the author had, in the composition of it, adopted the philosophy of Lord Bolingbroke, whom on this occasion he had followed as his guide, without understanding the tendency of his principles. In 1738, M. de Crousaz wrote some remarks on it, accusing the author of Spinozaism and naturalism; which falling into Warburton's hands, he published a defence of the first epistle, and soon afterwards of the remaining three, in seven letters; of which six were printed in 1739, and the seventh in 1740, under the title of "A Vindication of Mr Pope's Essay on Man, by the author of the Divine Legation." The opinion which Pope conceived of these defences, as well as of their author, will be best seen in his letters. In consequence, a firm friendship was established between them, which continued with undiminished fervour until the death of Pope; who, during the remainder of his life, paid a deference and respect to his friend's judgment and abilities, which will be considered by many as almost bordering on servility.

Towards the end of the year 1739, Warburton published a new and improved edition of the first volume of the Divine Legation; and in 1741 appeared the second part, which completed the argument, though not the entire plan of that work; "a work," says Bishop Hurd, "in all views of he most transcendant merit, whether we consider the in ntion or the execution. A plain simple argument, yet pe ectly new, proving the divinity of the Mosaic law, and la ng a sure foundation for the support of Christianity, is th e drawn out to great length by a chain of reasoning so ele antly connected, that the reader is carried along it wi ease and pleasure; while the matter presented to him is striking for its own importance, so embellished by a liv y fancy, and illustrated from all quarters by exquisite lea ning and the most ingenious disquisition, that in the wh le compass of modern or ancient theology there is no-thi g equal or similar to this extraordinary performance."[1]

his is the panegyric of a man reflecting with tenderne on the memory of his friend and benefactor; but it ap oaches much nearer to the truth than the censures of th e cabalistic critics who, fastening upon some weak pa of the Divine Legation, or perhaps never having looked in it, have ridiculously contended that the author was far fro being eminent as a scholar, and that his work is ini-mi l to the cause of Christianity. Putting partiality as e, there is in the Divine Legation of Moses abundant ev ence of the malignant folly of this charge, as no man ca read and understand that work without being convinced th its author was a Christian, not only sincere, but zealous; th he was what Johnson calls him, "a man of vigorous fa lties, of a mind fervent and vehement, supplied, by un-lin ed and incessant inquiry, with a wonderful extent and va ety of knowledge, which had neither depressed his imagi-na on nor clouded his perspicacity; and that to every work, an this work in particular, he brought a memory full fr ght, with a fancy fertile of original combinations, ex-er ng at once the powers of the scholar, the reasoner, and th wit." But we think it must be acknowledged, that hi earning was too multifarious to be always exact, and hi nquiries too eagerly pushed to be always cautious.

n the summer of 1741, Pope and Warburton, in a coun-tr ramble, took Oxford in their way. The university was na urally pleased at the arrival of two such strangers, and se ned desirous of enrolling their names among their gra-du es. The degree of D. D. was intended for the divine, an that of LL. D. for the poet: but intrigue and envy de ated this scheme; and the university lost the honour of ecorating at the same time the two greatest geniuses of he age, by the fault of one or two of its members. P e retired with some indignation to Twickenham, where he onsoled himself and his friend with this sarcastic reflec-tio : "We shall take our degree together in fame, what-ev we do at the university."

he friendship of this eminent poet was of service to W rburton in more respects than that of increasing his fa e. He introduced and warmly recommended him to m t of his friends, and among others to Mr Murray, after-w ls earl of Mansfield, and Ralph Allen, Esq. of Prior P k. In consequence of this introduction, we find War-b on at Bath in 1742. There he printed a sermon which h been preached at the Abbey-church on the 24th of O ober, for the benefit of Mr Allen's favourite charity, th General Hospital or Infirmary. During this year also h rinted a Dissertation on the Origin of books of Chivalry, at he end of Jarvis's preface to a translation of Don Q xote; of which Pope tells him he had not got over two pa graphs before he cried out, *Aut Erasmus, aut Diab s.*

n 1742, Warburton published "A Critical and Philoso-pl al Commentary on Mr Pope's Essay on Man, in which is ntained a Vindication of the said Essay from the Mis-re esentation of M. de Resnel, the French Translator, and of M. de Crousaz, Professor of Philosophy and Mathematics in the Academy of Lausanne, the Commentator." It was at this period, when he had the entire confidence of Pope, that he advised him to complete the Dunciad, by changing the hero, and adding to it a fourth book. This was accordingly executed in 1742, and the poem was published early in 1743, with notes by Warburton; who, in consequence of it, received his share of the abuse which Cibber liberally bestowed on both Pope and his annotator. In the latter end of the same year he published complete editions of "The Essay on Man," and "The Essay on Criticism;" and from the specimen which he there exhibited of his abilities, it may be presumed Pope determined to commit to Warburton's care the publication of those works which he should leave. At Pope's desire, he about this time revised and corrected the "Essay on Homer," as it now stands in the last edition of that translation.

The publication of the Dunciad was the last service which our author rendered Pope in his lifetime. After a lingering and tedious illness, the event of which had been long foreseen, this great poet died on the 30th of May 1744; and by his will, dated the 12th of the preceding December, bequeathed to Warburton one half of his library, and the property of all such of his works already printed as he had not otherwise disposed of or alienated, and all the profits which should arise from any edition to be printed after his death: but at the same time directed that they should be published without any future alterations.

In 1744, Warburton turned his attention to the several attacks which had been made on the Divine Legation, and defended himself in a manner which, if it did not prove him to be possessed of much humility or diffidence, at least demonstrated that he knew how to wield the weapons of controversy with the hand of a master. His first defence now appeared, under the title of "Remarks on several occasional Reflections, in answer to the Reverend Dr Middleton, Dr Pococke, the Master of the Charterhouse, Dr Richard Grey, and others; serving to explain and justify divers Passages in the Divine Legation, objected to by those learned Writers. To which is added, a general Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is considered the Relation the several Parts bear to each other and the whole. Together with an Appendix, in Answer to a late Pamphlet entitled An Examination of Mr W———'s second Proposition." This was followed next year by "Remarks on several occasional Reflections, in Answer to the Reverend Doctors Stebbing and Sykes; serving to explain and justify the two Dissertations in the Divine Legation, concerning the command to Abraham to offer up his Son, and the Nature of the Jewish Theocracy, objected to by these learned Writers. Part II. and last." Both these answers are couched in those high terms of confident superiority which marked almost every performance that fell from his pen during the remainder of his life.

On the 5th of September 1745, the friendship between him and Mr Allen was more closely cemented by his marriage with Miss Tucker. At that important crisis he preached and published three seasonable sermons: 1. "A faithful Portrait of Popery, by which it is seen to be the Reverse of Christianity, as it is the Destruction of Morality, Piety, and Civil Liberty. Preached at St James's, Westminster, October 1745." 2. "A Sermon occasioned by the present unnatural Rebellion, &c. Preached in Mr Allen's chapel at Prior Park, near Bath, November 1745." 3. "The Nature of National Offences truly stated. Preached on the General Fast-day, December 18, 1745–6." On account of the last of these sermons, he was again involved in a controversy with his former antagonist Dr Stebbing, which occasioned "An Apologetical Dedication to the Reverend Dr Henry Stebbing, in Answer to his Censure and Misrepresentations of the Sermon preached on the General Fast," &c.

---

[1] Hurd's Life of Warburton, prefixed to his Works.

Notwithstanding his great connections, his acknowledged abilities, and his established reputation, a reputation founded on the durable basis of learning, and upheld by the decent and attentive performance of every duty incident to his station, we do not find that he received any addition to the preferment given him in 1728 by Sir Robert Sutton (except the chaplainship to the prince of Wales), until April 1746, when he was unanimously called by the Society of Lincoln's Inn to be their preacher. In November he published "A Sermon preached on the Thanksgiving appointed to be observed the 9th of October, for the Suppression of the late unnatural Rebellion." In 1747 appeared his edition of Shakspeare and his Preface to Clarissa; and in the same year he published, 1. "A Letter from an Author to a Member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockburn's Remarks upon the Principles and Reasonings of Dr Rutherforth's Essay on the Nature and Obligations of Virtue, &c." 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philosophers, concerning the Nature of a Future State, and their Method of teaching by double Doctrine," (by Mr Towne) 1747, second edition.

"In 1749," says Bishop Hurd, "a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be least expected. An insignificant pamphlet, under the name of *A Patriot King*, was that year published by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was simply this: the manuscript of that trivial declamation had been intrusted to the care of Mr Pope, with the charge (as it was pretended) that only a certain number of copies should be printed. Mr Pope, in his excessive admiration of his guide, philosopher, and friend, took that opportunity, for fear so invaluable a treasure of patriot eloquence should be lost to the public, to exceed his commission, and to run off more copies, which were found, after his death, in the printer's warehouse. This charge, however frivolous, was aggravated beyond measure, and, notwithstanding the proofs which Lord Bolingbroke had received of Pope's devotion to him, envenomed with the utmost malignity. Mr Warburton thought it became him to vindicate his deceased friend; and he did it so effectually, as not only to silence his accuser, but to cover him with confusion."

About this time the publication of Dr Middleton's Inquiry concerning the Miraculous Powers of the Christian Church, gave rise to a controversy, which was managed with great warmth and asperity on both sides, and not much to the credit of either party. On this occasion Warburton published in 1750 an able performance, written with a degree of candour and temper which, it is to be lamented, he did not always exercise. The title of it is "Julian; or a Discourse concerning the Earthquake and fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jerusalem." A second edition of this discourse, with additions, appeared in 1751. During this year, he gave the public his edition of Mr Pope's Works, with notes, in nine volumes 8vo; and in the same year he printed "An Answer to a Letter to Dr Middleton, inserted in a Pamphlet entitled The Argument of the Divine Legation fairly stated," &c.; and "An Account of the Prophecies of Arise Evans, the Welsh Prophet in the last century," annexed to the first volume of Dr Jortin's Remarks on Ecclesiastical History

In 1752, Warburton published the first volume of a course of Sermons, preached at Lincoln's Inn, entitled "The Principles of Natural and Revealed Religion occasionally opened and explained;" and this was two years afterwards followed by a second. After the public had been some time promised, it may, from the alarm which was taken, be almost said threatened with, the appearance of Lord Bolingbroke's Works, they were about this time printed. The known abilities and infidelity of this nobleman had created apprehensions in the minds of many people, of the pernicious effects of his doctrines; and nothing but the appearance of his whole force could have convinced his friends how little was to be dreaded from arguments against religion so weakly supported. Many answers were soon published, but none with more acuteness, solidity, and sprightliness, than "A View of Lord Bolingbroke's Philosophy, in two Letters to a Friend." The third and fourth letters were published in 1755, with another edition of the two former; and in the same year a smaller edition of the whole; which, though it came into the world without a name, was universally ascribed to Warburton, and was afterwards publicly owned by him. To some copies of this is prefixed an excellent complimentary epistle from the president Montesquieu, dated May 26, 1745.

At this advanced period of his life, that preferment which his abilities might have claimed, and which had hitherto been withheld, seemed to be approaching towards him. In September 1754, he was appointed one of his majesty's chaplains in ordinary; and in the next year was presented to a prebend in the cathedral of Durham. About this time the degree of D. D. was conferred on him by Dr Herring, archbishop of Canterbury. A new impression of the Divine Legation being now called for, he printed a fourth edition of the first part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. During the same year appeared "A Sermon preached before his Grace Charles Duke of Marlborough, President, and the Governors of the Hospital for the Small-pox and for Inoculation, at the Parish-church of St Andrew, Holborn, April the 24th, 1755." And in 1756 he published "Natural and Civil Events the Instruments of God's Moral Government; a Sermon preached on the last public Fast-day, at Lincoln's Inn Chapel."

In 1757, Dr Warburton meeting with Mr Hume's tract entitled "The Natural History of Religion," filled the margin of the book, as well as some interleaved slips of paper, with many severe and shrewd remarks on the infidelity and naturalism of the author. These he put into the hands of his friend Dr Hurd, who, making a few alterations of the style, added a short introduction and conclusion, and published them in a pamphlet, entitled "Remarks on Mr David Hume's Natural History of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This fierce attack upon Mr Hume gave him so much offence that he thought proper to vent his indignation on the supposed author in the posthumous discourse which he called his *Life;* and thus to do greater honour to Dr Hurd than to any other of his numerous antagonists.

Towards the end of the year 1757, Dr Warburton was promoted to the deanery of Bristol; and in the beginning of the year 1760, he was, through Mr Allen's interest with Mr Pitt, afterwards earl of Chatham, advanced to the bishopric of Gloucester. That great minister is known to have declared, "that nothing of a private nature since he had been in office had given him so much pleasure as bringing our author on the bench." There was however another minister who dreaded his promotion, and thought he saw a second Atterbury in the new bishop of Gloucester; but Warburton, says Bishop Hurd, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence: he had other instruments of fame in his hands, and was infinitely above the vanity of being caught

> With the fine notion of a busy man.

He was consecrated on the 20th of January 1760, and on the 30th of the same month preached before the House of Lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762 he published "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity and the Abuses of Fanaticism," 2 vols. 12mo; and in the succeeding year drew upon himself much illiberal abuse from some writers of the popular party, on occasion of his complaint in the House of Lords, on the 15th of November 1763, against Mr Wilkes, for putting his name to certain notes on the infamous "Essay on Woman."

In 1765 he published a new edition of the second part of the Divine Legation, in three volumes; and as it had now received his last hand, he presented it to his great friend Lord Mansfield, in a dedication which deserves to be read. It was the appendix to this edition which produced the well-known controversy between him and Dr Lowth, which we have noticed elsewhere as doing no great honour, by the manner in which it was conducted, to either party. In the next year he gave a new and much improved edition of the Alliance between Church and State. This was followed, in 1767, by a third volume of Sermons, to which is added, his first triennial Charge to the Clergy of the Diocese of Gloucester; which may be safely pronounced one of the most valuable discourses of the kind that is to be found in our own or any other language. With this publication he closed his literary course; except that he made an effort towards publishing, and actually printed, the ninth and last book of the Divine Legation. This book, with one or two occasional sermons, and some valuable directions for the study of theology, has been given to the world in the splendid edition of his works by his friend and biographer the late bishop of Worcester. That prelate confesses that the ninth book of the Divine Legation displays little of the vigour of mind and fertility of invention which appear so conspicuous in the former volumes; but he adds, perhaps truly, that under all the disadvantages with which it passes, it is the noblest effort which has hitherto been made to give a *rationale* of Christianity.

While the bishop of Gloucester was thus exerting his last strength in the cause of religion, he projected a method by which he hoped to render it effectual service after his death. He transferred L.500 in trust to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, to found a lecture, in the form of a course of sermons, to prove the truth of revealed religion in general, and of the Christian in particular, from the completion of the prophecies in the Old and New Testament, which relate to the Christian church, especially to the apostasy of Papal Rome.

t is a melancholy reflection, that a life spent in the constant pursuit of knowledge frequently terminates in the loss of those powers, the cultivation and improvement of which are attended to with too strict and unabated a degree of ardour. This was the case with Dr Warburton; and it seems probable that the decline of intellectual vigour was aggravated by the loss of his only son, a promising young man, who died of a consumption but a short time before the bishop, who himself closed his career on the 7th of June 1779. In August 1781 his widow married John Stafford Smith, B. D., who had been his chaplain, and who in her right became owner of Prior Park. At her expense, and under the superintendence of Bishop Hurd, a collective edition of Warburton's Works was published in 1788 in seven vols. 4to. In 1794 he added "A Discourse by way of general Preface to the quarto Edition of Bishop Warburton's Works, containing some Account of the Life, Writings, and Character of the Author." This biographical work is liable to many objections. It is not only meagre and unsatisfactory in many of its details, but is deeply tinctured with the narrow prejudices and cool malignity of the writer. He left for publication, after his own death, "Letters from a late eminent Prelate to one of his Friends." This collection has no tendency to increase our reverence for either Warburton or Hurd. Here we must not entirely overlook the singular publication of Dr Parr, entitled "Tracts by Warburton and a Warburtonian, not admitted into the respective collections of their Works." Lond. 1789, 8vo.

WARD is variously used in our old books. A ward in London is a district or division of the city, committed to the special charge of one of the aldermen; and in London there are twenty-six wards, according to the number of the mayor and aldermen, of which every one has his ward for his proper guard and jurisdiction. A forest is divided into wards; and a prison is called a *ward*. Lastly, the heir of the king's tenant, that held *in capite*, was termed a *ward* during his nonage; but this wardship is taken away by the statute 12 Car. II. c. 24.

WARD, *Seth*, an English prelate, chiefly distinguished for his knowledge in mathematics and astronomy, was born at Buntingford in Hertfordshire; and his biographer Dr Pope places his birth in the year 1618. He was admitted of Sidney College, Cambridge, where he applied with great vigour to his studies, particularly to the mathematics, and was chosen fellow of his college. He was much involved in the consequences of the civil war, but he was more fortunate than many of his brethren. He was appointed Savilian professor of astronomy at Oxford; and here in 1654 he took the degree of D. D. In 1659 he was chosen president of Trinity College; but being disqualified for the office, he was obliged to resign it at the Restoration. In 1661 he became dean, and in 1662 bishop, of Exeter. In 1667 he was translated to Salisbury; and in 1671 was made chancellor of the order of the Garter. He was the first Protestant bishop that enjoyed that honour, and he procured it to be annexed to the see of Salisbury. Bishop Ward was one of those unhappy persons who have had the misfortune to survive their senses, which happened in consequence of a fever ill cured. He lived to the Revolution without knowing any thing of the matter, and died at Knightsbridge on the 6th of January 1689. He had rendered himself odious by the severities which he exercised against the non-conformists. He published various works on theology, philosophy, mathematics, and astronomy.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet prison, who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

WARDROBE, a closet or little room adjoining to a bedchamber, serving to dispose and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

WARDROBE, in a prince's court, is an apartment wherein his robes, wearing apparel, and other necessaries, are preserved under the care and direction of proper officers. In Britain, the Master or Keeper of the Great Wardrobe was an officer of great antiquity and dignity. High privileges and immunities were conferred on him by King Henry VI. which were confirmed by his successors; and King James I. not only enlarged them, but ordained that this office should be a corporation or body politic for ever. It was the duty of this office to provide robes for the coronations, marriages, and funerals of the royal family; to furnish the court with hangings, cloths of state, carpets, beds, and other necessaries; to furnish houses for ambassadors at their first arrival; cloths of state, and other furniture, for the lord lieutenant of Ireland, and all his majesty's ambassadors abroad; to provide all robes for foreign knights of the garter, robes for the knights of the garter at home; robes and all other furniture for the officers of the garter; coats for kings, heralds, and pursuivants at arms; robes for the lords of the treasury, and chancellor of the exchequer, &c.; livery for the lord chamberlain, grooms of his majesty's privy chamber, officer of his majesty's robes; for the two chief justices, for all the barons of the exchequer, and several officers of these courts; all liveries for his majesty's servants, as yeomen of the guard, and wardens of the Tower, trumpeters, kettle-drummers, and fifers; the messengers, and all belonging to the stables, as coachmen, footmen, littermen, postilions, and grooms, &c.; all the king's coaches, chariots, harnesses, saddles, bits, bridles, &c.; the king's watermen, game-keepers, &c.; also furniture for the royal yachts, and all rich embroidered tilts, and other furniture, for the barges. Besides the master or keeper of the wardrobe, who had a salary of L.2000, there were his deputy, who had L.150, and a comptroller and a patent clerk, each of whom had a salary of L.300; besides many other inferior officers and servants, who were all sworn servants to the king. There was likewise a removing wardrobe, which had its own set of officers, and standing wardrobe-keepers at St James's, Windsor Castle, Hampton Court, Kensington, and Somerset House; but the whole of the wardrobe establishment was abolished by act of parliament in 1782, and the duty of it in future was to be done by the lord chamberlain.

WARDSHIP, in chivalry, one of the incidents of tenure by knight-service. See FEUDAL SYSTEM.

WARE, a market-town of the county of Hertford, in the hundred of Braughin, twenty-one miles from London. It stands on the river Lea, which is navigable to the metropolis, and by which much malt, the principal commodity of the place, is conveyed to the great porter breweries and distilleries in London. It is a well-built town, and consists of one long street, with several minor ones intersecting it. The church is an ancient and noble structure. Near to it is the spring by which the new river is mainly supplied. Ware has a good market on Tuesday, and two yearly fairs. The population amounted in 1821 to 3844, and in 1831 to 4214.

WAREHAM, a market-town of the county of Dorset, in the hundred of Winfrith and division of Blandford, 112 miles from London. It is situated on an eminence between the mouth of the rivers Frome and Piddle, and consists of four principal and several minor streets. The river Frome is navigable up to the bridge for small craft from Poole. This was formerly a place of more importance, having once seventeen churches, now reduced to three, one only of which is used. There are however several dissenting places of worship. It was once fortified, and some remains of the works are still visible. It has very little trade. The market is on Saturday. It returns, with the parishes of Corfe Castle and Bere Regis, one member to parliament. The population of Wareham amounted in 1821 to 1939, and in 1831 to 2325.

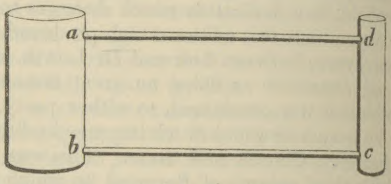
WARKWORTH, a town of the county of Northumberland, in the ward of Morpeth. It stands on the river Coquet, 308 miles from London. It consists of three streets, in which are good houses. It is remarkable for the extensive ruins of the castle of its name, belonging to the duke of Northumberland, with its park and hermitage. The market has declined. The population amounted in 1821 to 591, and in 1831 to 639.

WARMING. Under the article STOVE, the different means of heating apartments, both directly by stoves, and also by throwing in a supply of warm air, have been already noticed; and under the article STEAM, the means of using it as a source of heat for warming buildings and fluids, and also for drying articles, have been fully described. There is still another method of warming to which we have to advert; we mean by water. In considering the subject of heat, its communication from one object to another, and the mode by which it is conveyed through fluids, have been fully discussed; but before proceeding to describe the process of warming by water, it may be proper to allude to the circumstances accompanying the distribution of heat in this way.

When heat is applied to the end of a bar of iron, it passes from particle to particle, and the whole of the bar would in this way become warm, were it not for the operation of other causes. But the process of heating a fluid is different. When heat is applied to the bottom of a vessel of water, the particles below, as they receive caloric, are expanded, become specifically lighter, and ascend: cold particles must therefore fall to supply their place, which in their turn gain caloric and also rise; and in this way, by the constant ascent of warm and descent of cold particles, the whole of the fluid is heated. The communication of heat in this case is therefore not from particle to particle, as in solids, but by currents.

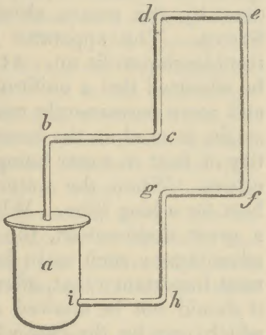
If, instead of a jar, an apparatus of the form fig. 1 be used, the currents will be established in *a b* when it is heated, and water will be found to flow from one vessel to another, owing to a difference in the gravity of the water in the different parts of the apparatus. Suppose at the commencement that the water is at 50°, and heat is applied to the bottom of *a b*. Owing to the currents, the fluid in it becomes warm, and is therefore of less specific gravity than before, while that in *c d* continues cold, and is consequently not altered in gravity; the pressure on *c*, occasioned by the column *d c*, is therefore greater than that on *b*, occasioned by the column *a b*. There is therefore a movement towards *b* corresponding to the difference in gravity, and consequent difference of pressure, on *c* and on *b*. As the water flows along *c b* into *a b*, there must be a flow along *a d* into *c d*, and this current in the circuit *a d c b* will continue as long as there is any difference between the temperature of the water in *a b* and *c d*. Now if *a b* have heat constantly applied to it, and *c d* be constantly parting with it by exposure to a colder atmosphere, there must be kept up a difference in temperature, and thus the current will be continued; and the heat which the water in *a b* receives will be given off during the circulation of the fluid along the other parts of the apparatus. Hence the mode of conveying heat generated by combustion to distant parts, as through the rooms of a house. The method to be followed will obviously depend on the construction of the building and the purposes for which the heat is required. If the whole of the apartments to be warmed are on the same level, the apparatus is very simple. At a convenient part of the building an open boiler is erected, and so situated that a fire can be kindled under it. From the upper part of the side of the boiler a tube, as *a d* in fig. 1, passes along the floor or near the floor, and is made to traverse on the same level to the distant parts, and again to return on the same level, and, after making a turn downwards at any convenient part, to enter the side of the boiler near the bottom, as at *b*, fig. 1. In this way the heat which the water in the boiler receives from the fire is conveyed by the fluid travelling along the tubes, and in its passage is communicated to the surrounding atmosphere of the apartment. The more rapidly the heat is abstracted from the tubes, the greater will be the difference between the temperature of the water in the boiler and in the other parts of the apparatus; the more rapid therefore will be the current, owing to the difference in gravity, and consequently the more abundant will be the supply of heat to the apartment.

Fig. 1.



In the method now described, the boiler is an open one, and being placed on it to prevent loss of heat by evaporation. The tube conveying the warm water cannot go above the level of the fluid in it, and hence this form of apparatus is restricted in its application. It is well adapted for hot-houses, for churches, and buildings with all the rooms on the same floor. When the apartments are situated one above another, such as in common dwelling-houses and in manufactories, the boiler must be a closed one, so that the water may be transported to a greater height. Numerous forms of apparatus have been recommended, and are now in use for this purpose. Suppose that the boiler is erected in a room on the lower part of the building, and that not only the apartments on the same level, but also those above, are to be warmed; all that is required is to carry a pipe from the upper part of the boiler through the different rooms, and after traversing these, to make it enter near the lower part of the boiler, as in the apparatus already described. Thus *a*, fig. 2, being the boiler, the water in it, when heated, will flow in the direction *a b c d e f g h*, and again into the boiler at *i*. If we suppose the pipes to traverse different apartments, then each apartment will receive heat from the water in its passage through it.

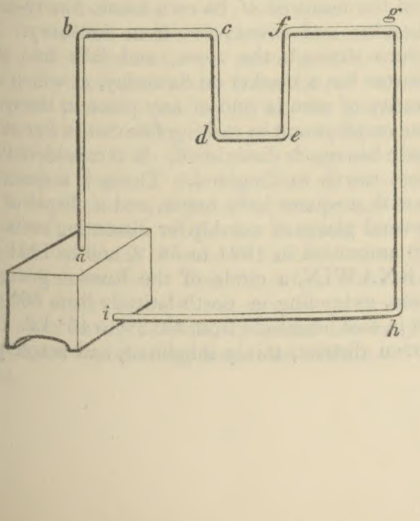
Fig. 2.



From what has been said of the currents in the fluid, it is evident, that as by the last process there must be a greater difference between the gravity of the water in the different parts of the apparatus the current must be more rapid, and consequently the heat from the original source must be more quickly carried away. There is evidently a limit to this; for when the height becomes great, the pressure on the pipes is greatly increased, which requires a corresponding strength in the materials, and a nicety in the junctures of the different parts of the apparatus. Not that there is any danger from the formation of high-pressure steam, so as to cause explosion; but should the tubes be faulty at any part, there would be an escape of hot water, which, under the pressure given by the high column, would rush out with great force.

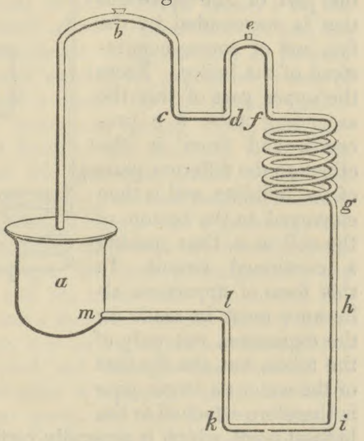
By using the shut boiler there is another advantage gained, namely, that of being able to carry the water downwards, and again upwards, at any particular part where it may be necessary, and, what is of still greater consequence, to convey it to a level above the boiler. In constructing an apparatus for this purpose, it must be borne in mind, that when the fluid has to rise after having descended, there is always a tendency to a retrograde motion, owing to the difference in pressure at different parts. Thus in a system of boiler and tubes, as in fig. 3, the ascent of the water from *a* to *b*, and its descent from *g* to *h*, and its return to the boiler, go on as in the other forms. At the same time, however, when the fluid flows from *c* to *d*, as that in *f e* is colder, and consequently of greater gravity, than that in *c d*, there is a tendency to cause a motion back again in the direction *f c d e*, and this will actually occur unless the descending force in *g h* be greater than that in *f e*. This is obtained by taking care to have the ascending pipe of sufficient height, and thus to cause a sufficient difference in the temperature, and consequent gravity, of the water, in the pipe passing from the boiler, and that in the descending tube *g h*. Much must depend on the size of the pipes, and the heat to be given off by the water in its passage along them; for, as already stated, the greater the difference between the temperature of the fluid in the ascending and descending tubes, the greater the difference in gravity, and consequently the more rapid the current. It has been found, that when the pipes are not to ascend after having descended, a sufficient current can in general be obtained when the exit from the boiler, as in fig. 1, is distant from the entrance to it about sixteen inches. When the pipe ascends after dipping, then the height to which the pipe ascending from the boiler must be carried should be in proportion to the descent and corresponding rise. Thus suppose, in fig. 3, the ascent from *e* to *f* is twelve inches, then the perpendicular height from *i*, where the water returns to the boiler, to *b*, ought to be twenty-eight, that is, sixteen inches greater than *e f*, or thereabouts; because, as already stated, the other circumstances affecting the current will cause a difference in the requisite height of the tubes.

Fig. 3.



By carrying the ascending tube to a considerable height, it thus affords the means of constructing an apparatus in which the ascent, after the pipe has dipt, may be much greater; and thus it is also that the pipe may be carried below the level of the boiler itself. In causing water to flow in an apparatus similar to that of fig. 4, a great deal of heat must be lost by the coil, owing to the great surface exposed; and the water will therefore become in it proportionally of great gravity compared to that in *a b*. At the same time, however, there is a tendency to a back-flow from *e* to *d*, and also in the lower part of the pipe *i h*, owing to the difference in temperature and gravity of the water in it and in *k l*. But if, owing to the great loss of heat from the coil, the gravity of the whole fluid in *e f g i*, be greater than that from *k* to *b*, then the flow will be established and kept up as long as the abstraction of heat from the coil is continued. It is evident, that by varying the form of an apparatus of this kind, water may be conveyed to the different parts of a building, though some of them are below the level of the boiler.

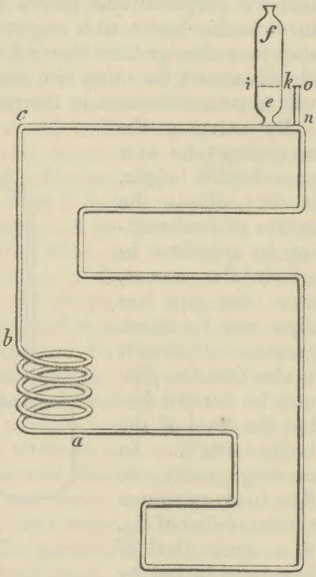
Fig. 4.



Different forms of boilers are used when the water is confined in a closed apparatus. Much must depend on the situation and on the particular purpose to which the system of heating is to be applied; and the same remarks are also applicable to the construction of the furnaces. When the boiler is a shut one, it is necessary to have a cistern to supply it with water, which must be placed above the highest part of the tubes. The most convenient place for the entrance of the pipe from it, is immediately before the water returns to the boiler: it is therefore generally connected with the return pipe just before it pierces the boiler.

It is well known that the expansion of iron by increase of temperature is considerable. The pipes must therefore be allowed free movement, so as to admit of expansion, otherwise they will give way. It is also necessary to have some contrivance for securing the escape of the air from the pipes, because, if left in, it impedes, nay sometimes prevents altogether, the current of the water; and hence the necessity of having an opening in the highest part of the tube, by which not only the air in them, but also that disengaged from the water when heated, will be expelled. The part at which this aperture must be placed will depend entirely on the form of the apparatus. In some, one opening will be sufficient, but in others two or more will be required; for though the air has a tendency to pass to the highest points, yet, from the difference in the levels, it may accumulate at different places. Thus, in fig. 4, it will be found at *b* and *e*, and hence at these points small tubes of a few inches in length, open at top, ought to be placed.

Fig. 5.



In addition to the forms of apparatus now described, there is still another now much in use, called the *High Pressure* apparatus. It consists of a coil of tubes, fig. 5, *a b*, about an inch external, and half an inch internal diameter, which is the part of the apparatus that is surrounded by the fire, and of course acts instead of the boiler. From the upper part of this the ascending tube *b c* proceeds, and from it the others to the different parts of the building, and is then conveyed to the bottom of the coil at *a*, thus making a continued circuit. In this form of apparatus, allowance must be made for the expansion, not only of the tubes, but also for that of the water; a larger pipe is therefore attached to the highest point, which is generally vertical, as *e f*. This tube being at first open, is employed for filling the apparatus; the water being poured in till it rises a little way in it, as, for instance, to the dotted line *i k*, after which the aperture is secured by a cap and screw. Instead of filling the apparatus through the expansion tube, a small one is sometimes attached to the highest part, as *n o*, after which the screw on it and on the safety-pipe are put on. By using this smaller tube, there is no risk of making the water too high, as it cannot rise above the dotted line *i k*.

In an apparatus of this kind, due attention must be paid to the strength of the tubes; because, as a strong heat is applied to the coil to raise the water beyond 212, were the tubes not of sufficient strength, they would be burst by the tendency to form steam of high elastic force. Thus the temperature of the coil is sometimes 500, at which the pressure on the inside of the pipes is upwards of 1000 lb. on the square inch; hence the necessity of having the pipes to be used proved to a pressure beyond this. Those employed are generally warranted to upwards of 2000 lbs. When an accident does occur, it is usually owing to the coil giving way, partly from its resisting force being weakened by the high temperature; partly from the action of the water on the iron, by which its properties are altered.

This high-pressure apparatus, though it has many advantages over the other forms, has also some disadvantages. The water in the coil can be heated to a greater degree than in a boiler, consequently more heat can be taken from the fire and conveyed to the apartments; but this, it is generally allowed, is done at a comparatively greater cost of fuel.

The system of heating by the transport of water from one place to another, as now described, has advantages which it is supposed recommend it above all others. It is well adapted for warming the air in large and extensive buildings, such as manufactories; and also for creating a requisite degree of heat for particular purposes, as in paper-making, drying of gunpowder, and many others. As yet, however, it remains to be proved whether it is equally economical with the more easy method of throwing into the apartment a large supply of air, moderately warmed, as is done by the means already described under the article STOVE. The apparatus itself is costly, and is more troublesome to fit up. At the same time, however, it must be admitted that a uniform temperature can be more easily and more permanently maintained by it than when air or steam is used as the heating medium, owing to the quantity of heat in water being great compared to that in the others. When the water is once warmed, it retains its heat for a long time. When uniformity of temperature is a great desideratum, the water system has therefore its advantages; such as in hot-houses, where it is of the utmost importance that, after the temperature is once raised, it should not be allowed again to sink, or to sink rapidly, which may be the case when an irregularity occurs in the fire of a hot-air or steam apparatus. With regard to the expense, we may state, that the cost of erecting a high-pressure apparatus used for heating a large wareroom amounted to L.70. The furnace is placed in a room below; and from the coil the ascending tube proceeds directly to the apartment above, and from it two tubes pass horizontally in different directions, and after traversing the room, return in the same direction, and join near where they took their origin, and then descend to the coil. The apartment is ninety-four feet in length, twenty-five in breadth at one place and forty-four at another, and varies in height at different places from fourteen to twenty-five feet. The cubic contents are in all very nearly 50,000 feet. The door opens directly to the street. Small coal is used, at five shillings and sixpence per ton, which lasts for two weeks, say for twelve days, at an expense therefore of about sixpence per day, by which the temperature is kept easily at 57°. Though this is a trifling expense, yet it is not less than would be required for a hot-air stove for the same apartment, while the original cost of the apparatus is much greater. (D. H.)

WARMINSTER, a market-town of the county of Wilts, in the hundred of its own name, ninety-seven miles from London and twenty-two from Salisbury. The river Willy runs through the town, and falls into the Avon. Warminster has a market on Saturday, at which the greatest quantity of corn is sold of any place in the county. It has some employment in making fine cloths, but of late years that trade has much diminished. It is considered one of the healthiest towns in England. There is a spacious parish church with a square lofty tower, and a chapel of ease, besides several places of worship for dissenting sects. The population amounted in 1821 to 5612, and in 1831 to 6115.

WARNAWIN, a circle of the Russian government of Kostroma, extending in north latitude from 56° 48′ to 57° 33′, and in east longitude from 43° 59′ to 46° 12′. It is a poor and barren district, thinly inhabited, and scarcely yielding cc sufficient for its scanty population, many of whom seek er loyment and subsistence in other provinces. It has but or town, its capital, of the same name, on the river Betlu. It does not contain more than 750 inhabitants. It is 56 miles from St Petersburg. Long. 44. 45. E. Lat. 57 20. N.

WARP, in the manufactures, a name for the threads, wh ther of silk, wool, linen, hemp, &c. that are extended ler thwise on the weaver's loom; and across which the we man, by means of his shuttle, passes the threads of the wef, to form a cloth, ribband, fustian, or the like.

WARP, a small rope employed occasionally to remove a sh from one place to another, in a port, road, or river. A hence,

To WARP, is to change the situation of a ship, by pulling he rom one part of a harbour, &c. to some other, by means of arps, which are attached to buoys, to anchors sunk in th bottom, or to certain stations upon the shore, as posts, ri s, trees, &c. The ship is accordingly drawn forwards to hose stations, either by pulling on the warps by hand, or y the application of some purchase, as a tackle, windlas or capstern, upon her deek. When this operation is pe ormed by the ship's lesser anchors, these machines, toge er with their warps, are carried out in the boats alterna ly towards the place where the ship is endeavouring to ar e; so that when she is drawn up close to one anchor, th other is carried out to a competent distance before her, an being sunk, serves to fix the other warp, by which she is rther advanced. Warping is generally used when the sa are unbent, or when they cannot be successfully empl ed, which may either arise from the unfavourable state of e wind, the opposition of the tide, or the narrow limits of e channel.

WARRANT is a power and charge to a constable or ot r officer to apprehend a person accused of any crime. It ay be issued in extraordinary cases by the privy counci or secretaries of state; but most commonly it is issued by ustices of the peace.

WARRANTY, Warrantia, in *Law*, a promise, or cove nt by deed, made by the bargainer for himself and his he s, to warrant and secure the bargainee and his heirs, ag nst all men, for enjoying the thing agreed on or granted be ween them.

WARREE, or Sawunt Warree, an extensive district of Hindustan, in the province of Bejapoor, situated betw en the sea and the western Ghaut Mountains, being fo y miles in length and about twenty-five in breadth. It is ocky and unproductive, and formerly the inhabitants we much addicted to piracy. In 1818 the British forces er red the country, and put an end to the government, al ving a pension to the ranny or female ruler.

WARREN is a franchise or place privileged by presc ption or grant from the king, for the keeping of beasts an fowls of the warren, which are hares and coneys, partri es, pheasants, and some add quails, woodcocks, and w er-fowl, &c. These being *feræ naturæ*, every one had a tural right to kill as he could; but upon the introducti of the forest-laws at the Norman conquest, these anim s being looked upon as royal game, and the sole prope y of our rude monarchs, this franchise of free-warren w invented to protect them, by giving the grantee a sole an exclusive power of killing such game, as far as his warre extended, on condition of his preventing other persons. A man therefore that has the franchise of warren, is in re ty no more than a royal gamekeeper; but no man, not ev a lord of a manor, could by common law justify sp ting on another's soil, or even on his own, unless he had th liberty of free-warren. This franchise is almost fallen in disregard since the new statutes for preserving the ga e, the name being now chiefly preserved in grounds th are set apart for breeding hares and rabbits.

WARRINGTON, a large market and borough town of the county of Lancaster, in the hundred of West Derby. It is a place of great though doubtful antiquity. Its name is most obviously of Saxon origin, Whocring in that language signifying an armed or defended town. It is placed on the river Mersey, over which a bridge was erected in 1496, by the first earl of Derby, to facilitate the progress of King Henry VII. in the north of England. As the best passage over the river, it was the scene of frequent conflicts during the civil war, and in the reign of Charles I. In 1643 the town was twice taken by storm by the parliamentary forces. In 1648 the Scottish army made a stand here; General Lambert here repulsed the troops who accompanied Charles II. on his way to Worcester; and in 1745 the centre arches of the bridge were broken down to impede the progress of the Highlanders under the Pretender. The old bridge having been frequently repaired, has been of late replaced by an elegant and convenient new erection.

There was at one period an establishment for the education of one class of dissenters, which had men of celebrity for tutors; among others Dr Priestley, Dr Enfield, Dr Aikin, and Gilbert Wakefield. It did not continue long, partly from insufficient funds, and partly from the difficulty of maintaining due discipline, so that it was dissolved about the year 1770, leaving no traces beyond an elegant poem by Mrs Barbauld, the daughter of Dr Aikin. There are three churches, one of which, dedicated to St Elphen or St Helen, is a handsome building of red freestone, probably of Saxon origin; and it contains some curious old monuments. Two ancient chapels remain, in one of which are some modern monuments of the Pattern family; in the other the magnificent tomb of Sir Thomas Boteler and his lady: the former was murdered in his mansion at Bewsey Hall. There are places of worship for almost every sect of protestant dissenters, and a chapel for the Roman Catholics. The schools are numerous, among which are pre-eminent the free-school founded and endowed in 1526 by the Boteler family, and the blue-coat school, which is a flourishing institution, and richly endowed for the education of 150 boys and forty girls. There is also a great number of Sunday schools, with many other charitable institutions. Among the public buildings, the most prominent are the town-hall, the market, and the cloth-hall. There are, besides, assembly-rooms and a theatre. As the Mersey is navigable up to the bridge, it is an important auxiliary to the intercourse with Liverpool, and through that town to foreign countries. Warrington is a place of great manufacturing industry. Cotton goods and sail-cloth are largely made; as also pins, files, and glass. It likewise supplies large quantities of malt. It is a station on the railroad between Birmingham and the towns of Liverpool and Manchester, being distant from the former seventy-eight miles, and from the two latter twenty miles. It is 173 miles from London. It has a well-supplied market on Saturday, where much corn is sold.

By the reform bill, Warrington has acquired the right of returning one member to the House of Commons; and it gives the title of earl, in addition to that of Stamford, to the Grey family. The population of the town amounted in 1821 to 12,570, and in 1831 to 16,018; but the whole parish, which extends beyond the town, contained, in 1831, 19,155 inhabitants.

WARRIOR, a town of Hindustan, in the Carnatic, thirty-eight miles north-east from Tanjore. Long. 79. 25. E. Lat. 11. 15. N.

WARSAW, the capital of the kingdom of Poland, is situated on the left bank of the Vistula, in north lat. 52° 14′, and east long. 21° 2′, in the midst of a vast sandy plain. The city proper is ill built, with narrow dirty streets; but the suburbs are fine and spacious, with wide, straight, and well-paved streets. At the close of 1835, the number of buildings or houses was 4298, of which 2968 were of stone, and 1330 of wood. The population at the same time amounted to 133,884, including 33,389 Jews. The royal palace is a vast structure; and, besides it, there is a great number of other fine palaces and public buildings, a cathedral dedicated to St John, and many other churches. Since the late revolution and re-subjugation of Poland, the Russian government has constructed a strong citadel at Warsaw, to overawe the Poles. The city still contains a number of scientific and literary establishments; but the principal ones, namely, the university, re-opened so lately as 1818, and the Royal Society of the Friends of Science, have been suppressed. Before the revolution, no other city in eastern Europe issued so great a number of periodical publications, in proportion to the amount of population; it was, besides, the centre of the industry and the commerce of the kingdom. The trade has again revived; and, in 1835, the principal articles manufactured in the town and exported were, carriages, in value 156,000 florins; pianofortes, 87,520; saddlery, 82,480; silver-plated ware, 82,180; carpets, 63,400; agricultural machines and implements, 47,850; woollen goods, 44,200. Praga, the largest suburb, situate on the right bank of the river, and connected with the city by a bridge of boats, is noted in the history of Poland for its terrible capture by Suwarrow in 1795. In the immediate neighbourhood of the city is the superb castle of Villanov or Willanow, built by the great king John Sobieski, who died here in 1696; and the island of Kepa-Saoka, embellished with gardens. Warsaw is 170 miles S. S. E. of Dantzig. (C. H.)

WARTON, Joseph, an elegant poet and critic, was born in the year 1722, in the house of his maternal grandfather, Joseph Richardson, rector of Dunsford in Surrey. His father, Thomas Warton, B. D. fellow of Magdalen College, and professor of poetry at Oxford, and afterwards vicar of Basingstoke in Hampshire, and of Cobham in Surrey, was descended from an ancient and honourable family of Beverley in Yorkshire. The son was for a short time sent to New College school, but was chiefly educated by his father till he reached the age of fourteen, when he was admitted on the foundation of Winchester College. He was at this early period distinguished by his love of poetry, and one of his school-fellows was William Collins. In September 1740, being superannuated, he was removed from Winchester; and as no vacancy occurred in New College, he was entered of Oriel, when he prosecuted his studies with diligence and success. In 1744 he took the degree of A. B., and was ordained to his father's curacy at Basingstoke, and officiated in that church till February 1746. He next removed to Chelsea, and afterwards to Cobham.

His father died in the year 1745, leaving two sons and a daughter in circumstances far from affluent. Joseph, his elder son, published by subscription a volume of "Poems on several occasions by the Rev. Mr Thomas Warton, Batchelor of Divinity, late Vicar of Basingstoke in Hampshire, and some time Professor of Poetry in the University of Oxford." Lond. 1748, 8vo. This volume is closed by two poems on the death of the author, one by his daughter Jane, the other by the editor. He had previously published a small collection of his own, entitled "Odes on various subjects." Lond. 1746, 4to. In 1748 the duke of Bolton presented him to the rectory of Winslade; and although this provision was but scanty, he immediately married Miss Daman, a young lady to whom he had for some time been enthusiastically attached. In 1751 he accompanied the same nobleman on a tour to the south of France. For this arrangement, as Dr Wooll very coolly informs us, the duke had two motives, "the society of a man of learning and taste, and the accommodation of a protestant clergyman, who immediately on the death of the duchess, then in a confirmed dropsy, could marry him to the lady with whom he lived, and who was universally known and distinguished by the name of Polly Peachum."[1] This, it must be admitted, was a very miserable commission for any protestant clergyman to undertake, nor did Warton earn the wages of his iniquity; for some unexplained reason induced or compelled him to revisit England, before the duchess died; and when, on her demise, he solicited the duke's permission to return, he had the mortification to learn that the worthy pair had been joined in wedlock by the chaplain to the embassy at Turin.

Before this period, he had undertaken a translation of the Eclogues and Georgics of Virgil; and having associated with it Pitt's translation of the Æneid, he added the original text, and accompanied the whole with his own notes. Lond. 1753, 4 vols. 8vo. The book is elegantly printed; but Dr Harwood remarks that the Latin text, especially in the Georgics, is extremely incorrect. A second edition followed in 1778. Warton added three essays, on pastoral, didactic, and epic poetry. This publication laid the foundation of his literary celebrity. Soon after its appearance, he was requested to assist Dr Hawkesworth in the Adventurer, which was commenced in 1752. The invitation was conveyed to him by Dr Johnson, who stated that the department destined for him was that of criticism. To this periodical work he contributed twenty-four papers, of which the greater part relate to critical subjects, and all of them are creditable to his talents and taste.

In 1754 he was instituted to the rectory of Tunworth; and in the following year he was elected second master of Winchester school. In 1756 Lord Lyttelton presented him with a chaplain's scarf. He now published the first volume of "An Essay on the Writings and Genius of Pope." Lond. 1756, 8vo. This is a very elegant and interesting morsel of criticism. Of his claims to the higher characteristics of a poet, Warton has formed a more moderate estimate than many other critics; but after all that has been written on his side of the question, the lively fancy, sparkling wit, and finished terseness of Pope have lost none of their attractions. This work, which appeared without the author's name, is dedicated to Dr Young, a professed admirer of original composition. In 1759 the university of Oxford conferred upon him by diploma the degree of A. M. In May 1766 he became head-master of Winchester school. For this situation he possessed several qualifications. He was a man of polished manners; nor could his pupils fail to imbibe some portion of his refined taste and love of literature. He was not however without defects. Though an elegant scholar, he was not sufficiently able as a philologist. "He held verbal criticism cheap, and, as a natural consequence, frequently encountered insurmountable difficulties in Greek authors; while the expedients to which he resorted in order to conceal the fact were easy of detection, and excited much amusement among the elder boys.... But Warton wanted other qualities essential to the head-master of a public school. He was inconsistent in his plans, and deficient in moral courage; often conceding with respect to points of discipline upon which he ought to have been inflexible. These defects paved the way for what was afterwards called *the Row*, when the school was in such a state of rebellion that the interference of the magistrates was required, and upwards of thirty of the boys were expelled. Burgess had left the school before this catastrophe occurred, but he used to tell, among other proofs of the insubordination which prevailed even in his time, that a riotous boy had the audacity, on one occasion, to hurl a Latin dictionary at Warton's head."[1]

---

[1] Wooll's Biographical Memoirs of the late Rev. Joseph Warton, D. D. p. 15. Lond. 1806, 4to.

On being placed at the head of this great school, Warton retired to Oxford, and accumulated the degrees of B. and D.D. In 1772 he lost his wife, by whom he had six children. Such a loss was severely felt; but he found himself helpless without the superintending care of a domestic companion; and in the course of the following year he married the daughter of Robert Nicholas, Esq. a descendant of Dr Nicholas, formerly warden of Winchester. From his scholastic toils he was accustomed to seek a relaxation in fashionable as well as literary society. His vacations were frequently spent in London. Like his brother, he became a member of the famous Literary Club; and being conspicuous for the vivacity and pleasantry of his conversation, the circle of his acquaintance was at once brilliant and extensive. His dignified friends did not however advance him to any eminent preferment. In 1782 Bishop Lowth conferred upon him a prebend of St Paul's and the living of horley in Hertfordshire, which he was permitted to exchange for Wickham. In the course of the same year, he published the second volume of his Essay on Pope. In 17 the interest of Lord Shannon procured him a prebend at Winchester; and to Lord Malmesbury he was indebted for the rectory of Easton, which, before the close of the year, he exchanged for Upham. The amount of these preferments was not inconsiderable, but they came too late to be of much avail to his family. He was sixty years of age before he had any benefice, except the small livings of W slade and Tunworth, and nearly seventy before he obtained those which afterwards fell to his share.

On the 23d of July 1793 he resigned his office of headmaster, and afterwards retired to his rectory of Wickham. His literary ardour was not yet extinguished; and a liberal offer from the London booksellers encouraged him to undertake a new edition of the works of Pope, which was published in the year 1797 in nine volumes octavo. For such a task he possessed many qualifications, but his edition did not escape the sharpness of critical reprehension. It was assailed with sufficient virulence by Mathias, in that great repository of literary and political malignity the Pursuits of Literature. He next undertook an edition of Dryden, and about the year 1799 he had completed two volumes, which were afterwards published. At a much earlier period of his life, he had projected a history of the revival of learning; and about the year 1784 he issued proposals for publishing "The History of Grecian, Roman, Italian, and French Poetry, in four parts." In this work, which was to occupy two quarto volumes, he however appears to have made little or no progress. All his labours and projects were terminated by an incurable disease in his kidneys; and he died on the 23d of February 1800, in the seventy-eighth year of his age. His widow survived till 18 . Besides three daughters, of whom the youngest was by his second wife, he left a son, the late John Warton, D. D. who published a work entitled "Death-bed Scenes."

Warton was a very elegant, rather than a very profound scholar; and with his classical learning he united much knowledge of modern literature, Italian and French as well as English. On subjects of criticism, he was an agreeable and instructive writer. His poems, which are but few in number, appear in the collection of Mr Chalmers. He is a skilful versifier, and is not destitute of poetic fancy. (X.)

WARTON, *Thomas*, the brother of Dr Warton, was born at Basingstoke in the year 1728. He was distinguished by his very early love of letters; and a tetrastich which he wrote at the age of nine, has been preserved by his biographer. He remained under the domestic tuition of his father till he was prepared for the university. On the 16th of May 1743, he was admitted a commoner of Trinity College, Oxford, and was soon afterwards elected a scholar of that house.

Warton.

He continued to cherish his love of poetry; and in 1747 he published without his name "The Pleasures of Melancholy," written two years before. On the appearance of Mason's "Isis, an Elegy," which contains reflections on the Jacobitical principles then prevalent at Oxford, Warton was encouraged by Dr Huddesfield, president of his college, to repel this attack. He accordingly published, in 1749, "The Triumph of Isis, occasioned by Isis, an Elegy." This poem, written at the age of twenty-one, extended his reputation. The principal of St Mary Hall, who is highly extolled for his Roman eloquence, sent the young author a present of five pounds. The same individual is likewise extolled for his patriotism. From the "Political and Literary Anecdotes of his own Times," published long after his death, it is evident that Dr King was deeply implicated in the schemes of the Jacobites; and we may thus ascertain the value of the commendation bestowed upon such a "patriot's fire."

Warton took the degree of A. M. on the first of December 1750, and in the course of the following year succeeded to a fellowship. He was thus placed in a situation well adapted to his character and pursuits. Though not rich, he was easy and independent, and had abundant leisure for the cultivation of those elegant studies in which he delighted. About this period he published various poems, either in a separate form or in some of the miscellaneous collections of the day. He was the editor of "The Union, or select Scots and English Poems," first printed at Edinburgh in 1753. This collection, of which there are three editions, includes several of his own poems; two of which, an ode and a pastoral, he has chosen to describe as written by a gentleman formerly of the university of Aberdeen. He afterwards published a work which evinces great knowledge of English literature, and a very sound spirit of criticism, "Observations on the Fairie Queene of Spenser." Lond. 1754, 8vo. An edition, in two volumes octavo, followed in 1762. The first edition was attacked in a scurrilous pamphlet, bearing the title of "The Observer observed; or, Remarks on a certain curious Tract, entitled Observations on the Fairie Queene of Spenser, by Thomas Warton, A. M." Lond. 1756, 8vo. This pamphlet, which appeared without the author's name, was written by Huggins, the unpoetical translator of Ariosto.

In 1757, on the resignation of Mr Hawkins of Pembroke College, he was elected professor of poetry. For this office, which is only tenable for ten years, he was eminently qualified by his taste as well as his learning; and we are informed that he exerted himself to fulfil its duties, by a constant recommendation of the elegance and simplicity of the classic poets. His lectures are said to have been remarkable for elegance of diction, and justness of observation. A specimen may be found in his dissertation "De Poesi Bucolica Græcorum;" which was originally delivered as one of these lectures, and having afterwards been enlarged, was prefixed to his edition of Theocritus.

His next publication was an elegant little collection entitled "Inscriptionum Romanarum Metricarum Delectus. Accedunt notulæ." Lond. 1758, 4to. The ancient are mixed with a few modern inscriptions. One of these, by Dr Jortin, had been printed as an ancient relique, in the Miscellaneous Observations on various Authors. Warton, who apparently entertained a doubt of its genuineness, has commended it as "conditissimum carmen." It however contains one very unhappy pentameter:

---

[1] Harford's Life of Thomas Burgess, D. D. late Lord Bishop of Salisbury, p. 5. Lond. 1840, 8vo.

> Utque tuus rursum corpore sim posito.

The editor has inserted four inscriptions written by himself, numbers 41, 44, 45, and 47, which he pretends were transmitted to him from Italy by a learned friend. This was evidently a mode of ascertaining his own proficiency as an imitator of ancient simplicity and elegance; but whether such a device is altogether excusable, may perhaps admit of some doubt.

To Dr Johnson's Idler he contributed three papers, Nos. 33, 93, and 96; but Dr Mant has erroneously stated that he was likewise a contributor to the Connoisseur, published by Colman and Thornton. In 1760 he printed two little works without his name. One of them is "A Description of the City, College, and Cathedral of Winchester." The other is entitled "A Companion to the Guide, and a Guide to the Companion; being a complete Supplement to all the Accounts of Oxford hitherto published." This facetious production speedily reached a third edition, and it was again printed at Oxford in 1806. He afterwards published "The Life and Literary Remains of Ralph Bathurst, M. D. Dean of Wells, and President of Trinity College in Oxford." Lond. 1761, 8vo. This volume, though chiefly interesting to the members of his own college, is not without its attractions to those who delight in the history of literature and its professors.

Reverting to his classical pursuits, he prepared for the press "Anthologiæ Græcæ, a Constantino Cephala conditæ, libri tres, ad editionem Lipsiensem Joannis Jacobi Reiske expressi. Accedunt interpretatio Latina, poetarum anthologicorum notitia, indices necessarii." Oxon. 1766, 8vo. Warton has contributed an elegant preface, together with some brief annotations. The Latin version, the elaborate account of the poets, and the six indices, are reprinted from Reiske's edition. After an interval of four years, he published a more elaborate work: "Theocriti Syracusii quæ supersunt, cum scholiis Græcis auctioribus, emendationibus et animadversionibus in scholia editoris et Joannis Toupii, glossis selectis ineditis," &c. Oxon. 1770, 2 tom. 4to. This edition is elegantly and correctly printed; and, in a letter to the editor, Toup described it as "the best publication that ever came from the Clarendon press." In compliance with the recommendation of the delegates, it was printed without accents, although Dr Foster, eight years before, had made a solemn remonstrance against a practice so heretical.[1] The scholia are not conveniently disposed for the purpose of reference; and in the opinion of Harles as well as Brunck, the editor has not to the full extent availed himself of all the valuable materials that were within his reach. But an edition of a Greek poet by a scholar so accomplished, and possessing so much elegance of taste, is not very frequently recorded in the annals of classical literature.

On the 7th of December 1767, he had taken the degree of B. D.; and on the 22d of October 1771, he was instituted to the small living of Kiddington in Oxfordshire, on the presentation of the earl of Lichfield, then chancellor of the university. From April 1755 to April 1774, he served the curacy of Woodstock, except during the long vacation. His pulpit oratory does not appear to have had any peculiar recommendation; but it was stated by an anonymous writer in 1803, that many were still alive who spoke of him with more regard and affection than of any other person who ever officiated at Woodstock. He likewise augmented his income by taking pupils; and Mr North, afterwards earl of Guildford, was placed under his care in 1774.

His situation in the university led to his next literary undertaking, "The Life of Sir Thomas Pope, Founder of Trinity College, Oxford; chiefly compiled from original evidences. With an Appendix of Papers never before printed." Lond. 1772, 8vo. This work, of which the original sketch was inserted in the Biographia Britannica, was reprinted in the year 1780. It extends to an ample volume, and is written with his usual elegance. The author's model is Bishop Lowth's Life of William of Wykeham; and both works afford very favourable examples of this species of biography, in which the details of the antiquary are rendered graceful by the taste of the scholar.

This was followed by a more important publication, namely, the first volume of "The History of English Poetry, from the close of the eleventh to the commencement of the eighteenth century. To which are prefixed two Dissertations: 1. On the Origin of Romantic Fiction in Europe: 2. On the Introduction of Learning into England." Lond. 1774, 4to. A second edition of this volume was speedily required. The second volume was published in 1778, and the third in 1781. To this last he prefixed "A Dissertation on the Gesta Romanorum." The impression of the work extended to 1250 copies; and the copy-right is said to have been purchased for three hundred and fifty pounds. He did not live to complete the plan which his title announces; for he only descended to the reign of Elizabeth. Although he survived the publication of the third volume for nine years, he had only printed eleven sheets of the fourth; nor does he appear to have left any additional portion of it in a state of preparation. At the end of an edition of his Poems, published in 1791, we find this announcement: "Speedily will be published, by the same author, the fourth and last volume of the History of English Poetry; in which the subject will [be] carried down to the commencement of the present century." It was the intention of Dr Warton to complete his brother's great work; but there is no evidence of his having made any progress in such an undertaking.

The History of English Poetry experienced a very favourable reception, and greatly contributed to extend the reputation of the author. With very extensive and variegated research Warton combines much knowledge of ancient and modern literature; and he enlivens the most unpromising disquisitions with many flowers of an active fancy and a refined taste. The book is written in an excellent English style, generally elegant and often graceful, never descending too low or rising too high. With these impressions of his great and conspicuous merit, we hold it to be impossible to acquiesce in the averment, that "his history has been found so dry and oppressive as to subdue the eagerness of the generality of readers." Such readers must certainly be in a very inadequate state of preparation. Soon after the appearance of his third volume, he was assailed in an anonymous pamphlet, entitled "Observations on the three first volumes of the History of English Poetry, in a familiar Letter to the Author." Lond. 1782, 4to. This familiar letter was the production of Ritson, and is plentifully furnished with his inexhaustible virulence. Warton, like every other man who has published a work in three volumes, has exhibited errors and mistakes; but those which his rabid censor has detected are neither so numerous nor so important as to warrant any great severity of reprehension. In spite of such critics as these, the work has steadily maintained as much popularity as could reasonably have been anticipated. A valuable edition, "carefully revised, with numerous additional notes by the late Mr Ritson, the late Dr [Mr] Ashby, Mr Douce, Mr Park, and other eminent antiquaries, and by the editor," was published by the late

---

[1] Foster's Essay on the different Nature of Accent and Quantity, p. 226. Eton, 1762, 8vo.

Richard Price, a man eminently qualified for the undertaking. Lond. 1824, 4 vols. 8vo. His preface, extending to 13 pages, is very able and elaborate; and the same remark is applicable to many of his annotations. Warton's transcripts from old manuscripts having too frequently been hasty and inaccurate, many of his errors are corrected by the editor. This edition, with additional notes by Sir Frederic Madden and other antiquaries, was reprinted in three volumes in the year 1840.

During the progress of his great work, he published a collection of his Poems. Lond. 1777, 8vo. A second edition appeared in 1778, a third in 1779, a fourth in 1789, and a fifth in 1791. This was followed by a more complete edition of "The Poetical Works of the late Thomas Warton, B. D." Oxford, 1802, 2 vols. 8vo. The editor, Dr Mant, now bishop of Down, has accompanied it with memoirs of his life and writings, and with notes critical and explanatory. His Poems are reprinted in the great collections of Dr Anderson and Mr Chalmers.

Warton took some share in the famous controversy respecting the poems produced by Chatterton. He published "An Enquiry into the Authenticity of the Poems attributed to Thomas Rowley; in which the Arguments of the Dean of Exeter and Mr Bryant are examined." Lond. 1782, 8vo. His opinion, it may easily be supposed, coincided with that of Tyrwhitt. He had now formed the plan of preparing a history of the county of Oxford. As a specimen, he had printed for the inspection of his friends, twenty copies of the History of the Parish of Kiddington; and an edition of it was afterwards published. Lond. 1783, 4to. In 1782 he was presented by his college to the donative of Hill Farrance in Somersetshire. In 1785 he was elected Camden professor of ancient history, on the resignation of Dr Scott, afterwards Lord Stowell. He had been a candidate for the same office in 1768, when one Vivian was preferred. On the fifth of May 1786, he read an inaugural lecture, written in his usual style of terse Latinity; but this seems to have been the full extent of his labours in his new department. In the course of the year 1785, he had succeeded Whitehead in the office of poet laureate; an office which, till a very recent period, continued to be held by a tenure sufficiently abject. The barbaric exaction to which the laureate was so long subjected, is not very creditable to the taste of the first three sovereigns of the Hanoverian dynasty. Soon after his appointment, Warton was treated with some degree of witty freedom, in a publication entitled "Probationary Odes for the Laureateship." But he had too much good nature to be easily annoyed; and, as his brother has stated, "he always heartily joined in the laugh, and applauded the exquisite wit and humour that appeared in many of these original satires."

The last of his literary labours was an edition of "Poems upon several occasions, English, Italian, and Latin, with Translations, by John Milton: viz. Lycidas, L'Allegro, &c. With notes, critical and explanatory." Lond. 1785, 8vo. A second edition, with many alterations and large additions, was published in 1791. One of these editions is an appendix containing "Remarks on the Greek Verses of Milton," by Dr Burney. It was the design of the editor to publish a second volume, comprehending Paradise Regained and Samson Agonistes. The notes exhibit a great variety of illustration, drawn from ancient as well as modern literature; but they are not unfrequently disfigured by the pitiful prejudices of a mere high-churchman. Dr Mant observes that "he has in one or two instances been guilty of an oversight, of which a remarkable example occurs in the note on the twenty-second verse of *Mansus*, where he attributes the life of Homer to Plutarch instead of Herodotus, and describes Mycale as a mountain in Bœotia instead of Asia Minor." The bishop evidently was not aware that there is one life of Homer ascribed to Plutarch and another to Herodotus. In the other part of his criticism he is more accurate; and Warton was apparently led into this small error by recollecting a passage of Ovid, where Mycale is grouped with a mountain of Bœotia:

Et Mycale, natusque ad sacra Cithæron.

He had now approached the termination of his distinguished career. Till he reached his sixty-second year, he had continued to enjoy vigorous and uninterrupted health. Having then been seized with the gout, he repaired to Bath, where he persuaded himself that a favourable change had taken place; but on his return to Oxford, his appearance did not convey the same impression to his friends. On the 20th of May 1790, he passed the evening in the common room of the college, and for some time was more cheerful than usual; but between ten and eleven o'clock, when only two of the fellows remained with him, he was suddenly affected with paralysis. He continued speechless, and only survived till two o'clock on the following day. His remains were deposited in the college-chapel, with the highest academical honours; the ceremony being attended not only by the members of his own college, but likewise by the vice-chancellor, heads of houses, and proctors.

The personal character of Thomas Warton presented many amiable aspects. In his manners, he was remarkably simple and unassuming. In the company of strangers, particularly those of a literary class, he was inclined to be shy and reserved; but, within the circle of his friends, his conversation was easy and gay, enriched with anecdote, enlivened with humour, besprinkled with puns, and sparkling with wit. His temper is described as habitually calm, his disposition as gentle, friendly, and forgiving. "His resentments, where he could be supposed to have any, were expressed rather in the language of jocularity than anger." Of Ritson's foul and unprovoked abuse, he only expressed his sense by calling him a black-letter dog. If he had possessed as much worldly wisdom as many of his brethren, he might probably have attained to much higher preferment in the church; but, apparently contented with his moderate provision, he continued to lead a tranquil and studious life, little infested with the cares of this world, and alike free from envy and ambition.

As a writer he has displayed varied excellence. He was an accurate as well as an elegant classical scholar; and to his masterly knowledge of English literature he added an extensive acquaintance with the polite literature of France and Italy. He was no mean poet, nor are his Latin inferior to his English verses. As a classical critic, he is advantageously known by his edition of Theocritus. Most of his publications are replete with variegated learning; but the great foundation of his fame is the History of English Poetry, a work which in its own department is unrivalled in English literature. (x.)

WARWICK, a borough and market town, the capital of the county of that name. It is within the hundred of Kington, and stands on the bank of the river Avon, seven miles from Stratford and ninety-one from London. It is a well-built and regular town. The county-hall is a fine structure, as is also the county gaol. It had once six parish churches, now reduced to two, St Mary's and St Nicholas. The former is a noble Gothic building, with several grand monuments to members of the noble family who derived their title from the town. The latter church is chiefly distinguished by its lofty tower and musical ring of bells. The most remarkable object connected with this place is the castle, the ancient and magnificent residence of the earl of Warwick, with its gardens, waterfall, bridge, collection of paintings, and other objects of attraction. As one of the most prominent residences of the English nobility, and one most connected with historical recollections, it is much visited, and is deserving of a more elaborate description than the limits of our work

Warwickshire.

will permit to be given here. Warwick is divided into two wards, and is governed by a corporate body, consisting of a mayor, six aldermen, and seventeen councillors; and it returns two members to the House of Commons. There is a market on Saturday, which is well supplied; and in addition there are no less than eight annual fairs. Within a few years the town of Leamington, one mile from Warwick, has, on account of its mineral waters, grown up to the resemblance of a new city, surpassing Warwick in population, and far exceeding it in the beauty and regularity of its edifices, both public and private. The inhabitants of Warwick amounted in 1821 to 8235, and in 1831 to 9109.

Boundaries, extent, and divisions.

WARWICKSHIRE, an inland county of England, and nearly in the centre of the kingdom. It is bounded on the western side, from north to south, by Staffordshire, Worcestershire, and Gloucestershire; and on the eastern side by Leicestershire, Northamptonshire, and Oxfordshire. Its greatest length from north to south is about forty-eight, and its breadth across the middle thirty-two miles. It contains 902 square miles, or 577,280 statute acres. It is divided into four hundreds, besides the city of Coventry, which, with its liberties, extends over about 18,000 acres. The hundreds are subdivided into several smaller portions, for the local administration of the law, in which petty sessions courts are held.

Population.

In no part of England has the population increased of late years in a greater ratio than in this county, the numbers at the several decennial censuses having been as follows, viz., in 1801, 208,130; in 1811, 228,733; in 1821, 274,392; in 1831, 336,610. If the augmentation has proceeded with the same rapidity as in the ten years from 1821 to 1831, it will be found at the enumeration of 1841, that the inhabitants have been doubled in forty years.

The number of inhabited houses in 1831 was 68,253, comprising 72,357 families. Of those families, 15,880 were chiefly employed in agriculture; 43,291 were chiefly occupied in trade, manufactures, and handicraft; and 13,186 were not comprised in either of the two preceding classes. The number of males twenty years of age was 83,239; the occupiers of land employing labourers were 2838; the occupiers of land not employing labourers, 1142; the labourers employed in agriculture were 15,644. The persons employed in manufacture or in making manufacturing machinery were 11,357; in retail trade, or in handicraft as masters or workmen, 32,579; the capitalists, bankers, professional or other educated men, 4012; the labourers in employments not agricultural, 10,358; the other males twenty years of age (except servants), 3729; male servants under twenty years of age, 3729; male servants more than twenty years of age, 1562; those under twenty years of age, 884; and female servants of all ages, 13,089.

Face of the country, and agriculture.

Although Warwickshire is an elevated district, it is in general level. The rivers flow with a languid course, and the undulations of the surface are rare and gentle. It is generally enclosed, and the fields are of moderate extent. The fences are for the most part high and umbrageous, being thickly planted with forest-trees, so that, though woods are rare, the face of the country seems, at a distance, to be one continued tract of woodland. There are but few common fields, and very little waste or barren land. The extent of pasture land is greater than in most parts of England, and is estimated to be more than half of the whole. The pasture land, calculated at 300,000 acres, may be said wholly to be appropriated to the sustenance of the different species of animals. 100,000 acres are annually mowed for hay, and the other two thirds are used for feeding. The agriculture of the country is well conducted. The cultivation of turnips is practised to a great extent, with much skill, and with very productive effects. The crops of wheat, barley, oats, pease, beans, and tares, are quite as luxuriant as in any portion of England. The cows are generally of the long-horned kind, but among them there are many varieties. The ancient breed of Warwickshire sheep has been crossed with the Leicester breed, and this mixture has produced a kind adapted to the land, and equal to any race in the kingdom.

The streams of this county are numerous, but, with the exception of the Avon, are inconsiderable; though, by the means of irrigation which they furnish, they are of great value to its rural economy. The whole of them run directly or indirectly to the Severn. The Avon is navigable for barges from Stratford to its junction with that river near Tewkesbury. The intercourse of the county is much facilitated by the numerous canals that intersect and connect it with every part of England; supply every part with cheap fuel; and serve to convey its heavy productions to the exporting towns, London, Liverpool, and Bristol. These canals are the Birmingham Old Canal, the Birmingham and Fazeley, the Warwick and Birmingham, the Worcester and Birmingham, the Coventry, the Warwick and Napton, the Stratford, the Ashby de la Zouch, and, above all, the Grand Junction. This county, as it is the central one of the kingdom, is become also a focal point for the most easy access from any one part of England to all the others. This has arisen from the magnificent railroad completed since 1834. A daily communication is by this great work kept up between London and the most distant cities of the kingdom. It enters the county near Rugby, and passes through Coventry to Birmingham, where it enters into Staffordshire; but in its passage sends out, or will soon do so, branches to the midland counties, as well as by Nottingham and Derby to York, from whence other branches will be formed to the most distant parts of the kingdom.

The minerals and fossils of this county are coal, iron, limestone, and freestone. At Leamington Priors are mineral springs, whose celebrity has made that place one of the resorts of fashionable company, as well as invalids. The waters contain neutral and sulphureous salts, with carbonate of iron. Owing to the growing reputation of these waters, the town, which in 1801 contained only 500 inhabitants, is said now to have increased its population to 12,000, and its beauty has similarly increased. The numerous objects of attraction near to it, and the fertility and salubrity of the neighbourhood, have added to the growth and prosperity of the place.

This county possesses considerable manufactories, of which the greatest are those in metals of all kinds, conducted upon a stupendous scale at Birmingham, and the towns and villages in its vicinity. The minute divisions and subdivisions of labour, the various mechanical inventions, the discoveries in chemistry, and the industrious and economical habits of the people, have rendered this part of the country the principal reservoir from whence the world is supplied with domestic utensils, ornaments, and a thousand minute articles which add much to the comfort of civilized life. The city of Coventry has long been celebrated for its manufactures of ribbons, and other goods of silk, which now give occupation, in that place and its vicinity, to more than 15,000 persons. There are also at Coventry large undertakings for making watches; a trade that has of late been much extended. Mills for spinning cotton and wool have been erected at Warwick; and to them is attributed the great increase which has lately taken place in the population of that town. At Tamworth very large works are constructed for printing calicoes. At Alcester, several hundred persons are employed in making needles. In several parts of the county much linen yarn is spun.

The most remarkable objects in the county are Kenilworth Castle, now in a dilapidated state; Maxstoke Castle, a most extensive pile; Comb Abbey, a Cistertian convent; the school-house at Rugby; and the house at Stratford in which Shakspeare was born.

This county has furnished titles to two British peers, the earl of Warwick and the earl of Coventry; and one Irish peer, Baron Arden. For election purposes, the county is divided into two parts, distinguished as the northern and southern. The election for the northern division is held at the town of Coleshill; and the other polling places are Nuneaton, Coventry, Birmingham, and Dunchurch. The election for the southern division is held at Warwick; and the other polling places are Kineton, Stratford, Henley, and Southam. Two members from Warwick, two from Coventry, and since the reform act two from Birmingham, are sent to the House of Commons. Two are also sent from Tamworth, the largest part of which is in the adjoining county of Stafford.

The towns of more than 3000 inhabitants, and their population, were, in 1831,

Birmingham	146,986
Coventry	27,070
Warwick	9,109
Nuneaton	7,799
Atherstone	3,871
Sutton Colefield	3,684
Stratford on Avon	3,488
Kenilworth	3,097

The most remarkable among a great number of noblemen and gentlemen's seats are, Warwick Castle, earl of Warwick; Ragley Hall, marquis of Hertford; Walton Hall, Sir C. Mordaunt; Compton Verney, Lord Willoughby; Guy's Cliff, B. Greathead; Great Packington, Lord Aylesford; Compton Wyngate, marquis of Northampton; Astley Castle; Newdigate; Hewill Grange, earl of Plymouth; and Merevale, D. S. Dugdale.[1]

WARYE, an open town of Hindustan, in the province of Gujerat and district of Werrear, fourteen miles south-west from Ruhdunpoor. It is the residence of many of the hill jhuts, and can muster from 800 to 1000 horsemen, well mounted, and armed with spears and sabres.

WASA, a circle of the Russian province of Finland, which extends over 16,760 miles, comprehending six cities, 225 hamlets or farms, with 145,700 inhabitants. The capital is the town of the same name, on a bay in the Baltic Sea. It is well built, though chiefly with wooden houses, but has a handsome stone church. It contains 630 dwellings, with 2830 inhabitants, who make some leather, and export many deals, much pitch, and some little corn; but the harbour is nearly choked up with sand. Long. 21. 30. E. Lat. 63[illegible]. 35. N.

WASH, among distillers, the fermentable liquor used by malt distillers. See BREWERY.

WASHINGTON, the capital of the United States of North America, is finely situate on undulating ground in the angle formed by the junction of the navigable river Potomac with the Eastern Branch, in the centre of the federal district of Columbia, an area of 100 square miles, ceded by the states of Virginia and Maryland to the United States for the site of their capital. The plan of the city, as originally laid out, forms nearly a parallelogram of about four miles by two and a half, consisting of streets crossing at right angles in the direction of the cardinal points, and traversed diagonally by larger avenues, named after the several states of the union; but only a small portion of the plan has yet been executed, and the city consists only of straggling clusters of houses placed at inconvenient distances from each other. Almost the only part that is compactly built is that which extends along Pennsylvania avenue, between the president's house and the Capitol, both of which are handsome buildings of white freestone. The Capitol contains the halls of the senate and house of representatives, the library of congress, and numerous other apartments, some of which are spacious and tastefully embellished. It is a large square building, surmounted in the centre by a massy dome, its eastern front adorned with a Corinthian colonnade, and it is surrounded by grounds tastefully planted and laid out. There are various other public buildings, of neat and substantial but unpretending architecture, as the city hall, the halls of Columbia College, the penitentiary, twenty churches, the medical hall, &c. About a mile south-east of the Capitol is the navy-yard, on Eastern Branch, which is deep enough along shore for the largest vessels; and just above it is the naval hospital. At the junction of the two rivers stands the United States arsenal. The principal educational establishment is Columbia College, founded by the Baptists, with nine instructors, besides four professors connected with the medical department. The city was founded in 1791, and became the seat of government in 1800. In 1830 the population amounted to 18,827, including 3129 free blacks and 2319 slaves; but during the sessions of congress the place is thronged with visitors from all parts of the world. Notwithstanding its advantageous situation on a large navigable river, and in the centre of a productive country, Washington has never become the seat of trade; and its growth is solely to be attributed to the expenditure of government and the public functionaries. It has a bridge, one mile in length, over the Potomac, leading to Alexandria, and two across Eastern Branch. The Baltimore Railroad affords an easy communication with the north, the Chesapeake and Ohio Canal with the west, and the Potomac, to different points, on which regular lines of steam-packets run, with the south. Long. 76. 58. W. Lat. 38. 55. N. (C. H.)

WASHINGTON, GEORGE, the first president of the United States, was born in the year 1732, in the parish of Washington, in Virginia. He was descended from an ancient family in Cheshire, of which a branch was established in Virginia about the middle of the seventeenth century. Little is known concerning his education, or the early years of his life. Before he was twenty years of age, he was appointed a major in the colonial militia, and had then an opportunity of displaying those military and political talents which have since rendered his name so famous throughout the world. In the disputes which arose between the French and English officers, about settling the limits of Canada and Louisiana, Major Washington was employed by the governor of Virginia as a negotiator, and he succeeded in preventing a threatened invasion of the English frontiers by the French and their Indian allies; but in the following year, when hostilities seemed inevitable, he was appointed lieutenant-colonel, and soon after to the command of a regiment raised by the colony for its own defence. In 1755, Colonel Washington served as a volunteer in the unfortunate expedition of General Braddock; and in that expedition, which was attended with great difficulty, he exhibited so much calmness and intrepidity, that the utmost confidence was reposed in his talents, and perfect obedience paid to his commands, by the whole army. After having been employed in a different and more successful expedition, to the river Ohio, the state of his health required him, about the year 1758, to resign his military situation; and in the sixteen following years, during which period he married Mrs Custis, a Virginian lady of amiable character and respectable connections, it would appear that he resided chiefly at his beautiful seat of Mount Vernon, and was occupied in the cultivation of his estate.

---

[1] See Dugdale's Antiquities of Warwickshire; Marshall's Rural Economy; Hutton's History of Birmingham; Beauties of England and Wales.

When the disaffection of the Americans to the British government had become pretty general, and had at last spread to the colony of Virginia, Colonel Washington was appointed a delegate from that state to the congress which met at Philadelphia on the 26th October 1774; and soon after he was appointed to the command of the American army, which had assembled in the provinces of New England. The conduct of Washington during the whole of the war, as well as during the period when he presided in the government of the United States, has been so fully detailed in other parts of this work, that it would be unnecessary repetition even to give a general outline of it in this place.

Washington resigned the presidency in 1796, after having published a farewell address to his countrymen. This address was remarkably distinguished for the simplicity and ingenuousness, moderation and sobriety, the good sense, prudence, and honesty, as well as sincere affection for his country and for mankind, which the author of it had always exhibited. It seemed to be a perfect picture of his whole life. From the time of his resignation till the month of July 1798, he lived in retirement at his seat of Mount Vernon. At this period, when the unprincipled actors in the French revolution were carrying on their wicked machinations in every part of the world to which their influence extended, the United States resolved to arm by land and sea in their own defence. General Washington was called from his retirement, and the command of the army was bestowed upon him. This he accepted, because he considered, as he himself expressed it, "every thing we hold dear and sacred was seriously threatened, although he had flattered himself that he had quitted for ever the boundless field of public action, incessant trouble, and high responsibility, in which he had long acted so conspicuous a part." In this situation he continued during the remaining short period of his life. On Thursday the 12th of December 1799, he was seized with an inflammation in the throat, and was carried off on Saturday the 14th of the same month, in the sixty-eighth year of his age. In his dying moments he displayed the same calmness, simplicity, and regularity, which had uniformly marked his conduct through life. He saw the approaches of death without fear, and he met them without parade. The well-ordered state of his private affairs bore the stamp of that constant authority of prudence and practical reason over his actions which was always the most prominent feature of his character. His name will ever be remembered by, and precious to, all well-wishers of mankind and of liberty, as that of the most prudent commander and the most virtuous ruler that history has recorded. His life has been written by Marshall, chief justice of America, and by Mr Sparks; and his state-papers have been published, with an eloquent eloge, by M. Guizot.

WASIL, a circle of the Russian government of Nishegorod, extending in north latitude from 55° 52′ to 56° 40′, and in east longitude from 45° 5′ to 46° 22′. It is watered by the rivers Wolga, Sura, and Wetluga, is of moderate fertility, yielding corn, but more pasturage. The population is 110,000, who find much employment in making mats from the bark of the trees. The capital is a town of the same name, situated on the river Sura, where it falls into the Wolga. It is chiefly built of wood, and contains 1500 inhabitants. It is 881 miles from St Petersburg. Long. 46. 6. E. Lat. 63. 52. N.

WASILKOW, a circle in the Russian government of Kiew, extending in north latitude from 49° 39′ to 50° 13′, and in east longitude from 31° 47′ to 32° 23′. It has the river Dnieper as its eastern boundary, and the banks are both fertile and picturesque. It has good meadows, extensive woods, and yields a surplus of corn. The capital is of the same name. Though called a city, it does not contain 1000 inhabitants, who are mostly Jews. It stands on the river Stugena, and is 881 miles from St Petersburg. Long. 32. 55. E. Lat. 50. 12. N.

WASSAH, a town of Hindustan, in the province of Gujerat, eighteen miles north by east from Cambay. Long. 72. 52. E. Lat. 22. 39. N.

WASSOTA, a celebrated fortress of Hindustan, in the province of Bejapore and district of the Concan. There are two forts, situated on rocks nearly perpendicular, and 3000 feet high. They were surrendered in 1818 to a British force, notwithstanding their strength.

WATCH. See Clock and Watch Work.

WATCHET, a market-town of the county of Somerset, in the hundred of Willerton and Freemanners, 158 miles from London. It is a seaport, situated on the Bristol Channel, but its harbour has been much neglected; and though means have been taken to improve it, small vessels only can enter it. Watchet was formerly a place of repute for making a kind of coarse cloth, well known in the western counties by the name of the place. It is in summer visited for the purpose of sea-bathing. It is within and forms the chief part of the parish of St Deucemans, whose population amounted in 1821 to 1865, and in 1831 to 2120.

WATEEHOO, an island in the South Pacific Ocean, about six miles long and four broad, discovered by Captain Cook in 1777. Long. 158. 15. W. Lat. 20. 1. S.

WATER, a well-known fluid, diffused through the atmosphere, and over the surface of the globe, and abounding in a certain proportion in animals, vegetables, and minerals. See Physical Geography.

Water, *Holy*, is used in the church of Rome, as also by the Greeks, and by the other Christians of the east of all denominations; and it consists of water with a mixture of salt, blessed by a priest according to a set form of benediction. It is used in the blessing of persons, things, and places; and is likewise considered as tending to excite pious thoughts in the minds of the faithful. The priest, in blessing it, first, in the name of God, commands the devils not to hurt the persons who shall be sprinkled with it, or to abuse the things, or disquiet the places, which shall likewise be so sprinkled. He then prays that health, safety, and the favour of heaven, may be enjoyed by such persons, and by those who shall use such things, or dwell in such places. Vestments, vessels, and other such things that are set apart for divine service, are sprinkled with it. It is sometimes sprinkled on cattle, with an intention to free or preserve them from diabolical enchantments; and in some spiritual books there are prayers to be said on such occasions, by which the safety of such animals, as being a temporal blessing to the possessors, is begged of God, whose providential care is extended to all his creatures. As a ceremony, says the Catholic, water brings to our remembrance our baptism, in which, by water, we were cleansed from original sin. It also puts us in mind of that purity of conscience which we ought to endeavour always to have, but especially when we are to worship our God. The salt, which is put into the water to preserve it from corrupting, is also a figure of divine grace, which preserves our souls from the corruption of sin; and is likewise an emblem of that wisdom and discretion which ought to season every action that a Christian does, and every word that he says. It is wont to be blessed and sprinkled in churches on Sundays, in the beginning of the solemn office. It is kept in vessels at the doors of the same churches, that it may be taken by the faithful as they enter in. It is also often kept in private houses and chambers.

Water-Spout, an extraordinary meteor, consisting of a large mass of water collected into a sort of column, and moved with rapidity along the surface of the sea. See Physical Geography.

WATER-WORKS.

UNDER this name may be comprehended almost every hydraulic structure or contrivance; such as canals, conduits, locks, mills, water-engines, &c. But they may be conveniently classed under two general heads, 1st, works which have for their object the conducting, raising, or otherwise managing, of water; and, 2dly, works which derive their efficacy from the impulse or other action of water. The *first* class comprehends the methods of simply conducting water in aqueducts or in pipes for the supply of domestic consumption or the working of machinery. It comprehends the methods of procuring the supplies necessary for these purposes, by means of pumps, water or fire engines. It also comprehends the subsequent management of the water thus conducted, whether in order to make the proper distribution of it according to the demand, or to employ it for the purpose of navigation, by lockage, or other contrivances. And in the prosecution of these things many subordinate problems will occur, in which practice will derive great advantages from a scientific acquaintance with the subject. The *second* class of water-works is of much greater variety, comprehending almost every kind of hydraulic machine; and would of itself fill volumes. Many of these have already occurred in various articles of this work, particularly in HYDRODYNAMICS, part iii.—*On Hydraulic Machinery.* In describing or treating them, we have tacitly referred the discussion of their general principles, in which they all resemble each other, to some article where they could be taken in a connected body, susceptible of general scientific discussion, independent of the circumstances which of necessity introduced the particular modifications required by the uses to which the structures were to be applied. That part of the present article, therefore, which embraces these common principles, will chiefly relate to the theory of water-mills, or rather of water-wheels; because, when the necessary motion is given to the axis of the water-wheel, this may be set to the performance of any task whatever.

CLASS I.

Of the Conducting of Water.

This is undoubtedly a business of great importance, and forms a principal part of the practice of the civil engineer: it is also a business so imperfectly understood, that we believe that very few engineers can venture to say, with tolerable precision, what will be the quantity of water which his work will convey, or what plan and dimensions of conduit will convey the quantity which may be proposed.

In the article RIVER we have given a sort of history of the progress of our knowledge in hydraulics, a branch of mechanical philosophy which seems to have been entirely unknown to the ancients. Even Archimedes, the author of almost all we know in hydrostatics, seems to have been entirely ignorant of any principle by which he could determine the motion of water. The mechanical science of the ancients seems to have reached no farther than the doctrine of equilibrium among bodies at rest. Guglielmini first ventured to consider the motion of water in open canals and in rivers. Its motion in pipes had been partially considered in detached portions by others, but not so as to make a body of doctrine. Sir Isaac Newton first endeavoured to render hydraulics susceptible of mathematical demonstration: but his fundamental proposition has not yet been freed from very serious objections; nor have the attempts of his successors, such as the Bernoullis, Euler, D'Alembert, and others, been much more successful: so that hydraulics may still be considered as very imperfect, and the general conclusions which we are accustomed to receive as fundamental propositions are not much better than matters of observation, little supported by principle, and therefore requiring the most scrupulous caution in the application of them to any hitherto untried case. When experiments are multiplied so as to include as great a variety of cases as possible, and when these are cleared of extraneous circumstances, and properly arranged, we must receive the conclusions drawn from them as the general laws of hydraulics. The experiments of the Abbé Bossut, narrated in his *Hydrodynamique*, are of the greatest value, having been made in the cases of most general frequency, and with great care. The greatest service, however, has been done by the Chevalier du Buat, who saw the folly of attempting to deduce an accurate theory from any principles that we have as yet learned, and the necessity of adhering to such a theory as could be deduced from experiment alone, independent of any more general principles. Such a theory must be a just one, if the experiments are really general, unaffected by the particular circumstances of the case, and if the classes of experiment are sufficiently comprehensive to include all the cases which occur in the most important practical questions. Some principle was however necessary for connecting these experiments. The sufficiency of this principle was not easily ascertained. Du Buat's way of establishing it was judicious. If the principle is ill-founded, the results of its combination in cases of actual experiments must be irregular; but if experiments, seemingly very unlike, and in a vast variety of dissimilar cases, give a train of results which is extremely regular and consistent, we may presume that the principle, which in this manner harmonizes and reconciles things so unlike, is founded on the nature of things; and if this principle be such as is agreeable to our clearest notions of the internal mechanism of the motions of fluids, our presumption approaches to conviction.

Proceeding in this way, the Chevalier du Buat has collected a prodigious number of facts, comprehending almost every case of the motion of fluids. He first classed them according to their resemblance in some one particular, and observed the differences which accompanied their differences in other circumstances; and by considering what could produce these differences, he obtained general rules, deduced from fact, by which these differences could be made to fall into a regular series. He then arranged all the experiments under some other circumstances of resemblance, and pursued the same method; and by following this out, he has produced a general proposition, which applies to the whole of this numerous list of experiments with a precision far exceeding our utmost hopes.

We must however observe, that of this list of experiments there is a very large class which is not direct, but requires a good deal of reflection to enable us to draw a confident conclusion; and this is in cases which are very frequent and important, viz. where the declivity is exceedingly small, as in open canals and rivers. The experiments were of the following forms. Two large cisterns were made to communicate with each other by means of a pipe. The surfaces of the water in these cisterns were made to differ only by a small fraction of an inch; and it is supposed that the motion in the communicating pipe will be the same as in a very long pipe, or an open canal, having this very minute declivity. We have no difficulty in admitting the conclusion; but we have seen it contested, and it is by no means intuitive. We had entertained hopes that this important case would have been determined by direct experiments, which the writer of this article was commissioned to make by the Board for Encouraging Improvements and Manufactures in Scotland; but the infirm state of his health was always an effectual bar to the accomplishment of this desirable object. This however need not occasion any hesitation in the adoption of the Chevalier du Buat's general proposition, because the experiments which we are now criticising fall in precisely with the general train of the rest, and show no *general* deviation which would indicate a fallacy in principle.

We apprehend it to be quite unnecessary to add much to what has been already delivered on the motion of waters in an open canal. Their *general progressive* motion, and consequently the quantity delivered by an aqueduct of any slope and dimension, are sufficiently determined; and all that is wanted is the tables referred to in the article River, by which any person who understands common arithmetic may compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe. These tables, which with great labour have been computed for this work, here follow.

Table I. *Logarithms of the Values of the Numerator of the Fraction* $\frac{307\ (\sqrt{d}-0\cdot1)}{\sqrt{s}-\text{L}\sqrt{s+1\cdot6}}$ *for every Value of the Hydraulic mean Depth* d: *also the Value of* 0·3 ($\sqrt{d}$—0·1).

d.	Log. of 307 ($\sqrt{d}$—0·1)	0·3 × ($\sqrt{d}$—0·1)	*d.*	Log. of 307 ($\sqrt{d}$—0·1)	0·3 × ($\sqrt{d}$—0·1)	*d.*	Log. of 307 ($\sqrt{d}$—0·1)	0·3 × ($\sqrt{d}$—0·1)	*d.*	Log. of 307 ($\sqrt{d}$—0·1)	0·3 × ($\sqrt{d}$—0·1)
0,1	1·82208	0,06	4,9	2·81216	0,63	9,7	2·96634	0,90	54	3·34738	2,17

TBLE I. consists of three columns. *Column* 1, entitled *d*, c tains the hydraulic mean depths of any conduit in incl. This is set down for every tenth of an inch in the first en inches, that the answers may be more accurately obt ed for pipes, the mean depth of which seldom exceed three or four inches. The column is continued to 100 nches, which is fully equal to the hydraulic mean dep of any canal.

Column 2 contains the logarithms of the values of $\sqrt{d}-0·1$, multiplied by 307; that is, the logarithm of the numerator of the fraction $\frac{307\,(\sqrt{d}-0·1)}{\sqrt{s}-\text{L}\sqrt{s+1·6}}$ in the article RIVER.

Column 3 contains the product of the values of $\sqrt{d}-0·1$ multiplied by 0·3.

TABLE II. consists of two columns. *Column* 1, entitled *s*, contains the reciprocal of the number expressing the slope or declivity of any pipe or canal; that is, the quotient of its length divided by the elevation of one extremity above the other. Thus, if a canal of one mile in length be three feet higher at one end than the other, then *s* is $\frac{5280}{3} = 1760$.

Column 2 contains the logarithms of the denominators of the above-mentioned fraction, or of the different values of the quantity $\sqrt{s} - \mathrm{L}\sqrt{\overline{s + 1{\cdot}6}}$.

Examples of the use of these Tables.

Example 1. Water is brought into the city of Edinburgh in several mains. One of these is a pipe of five inches diameter. The length of the pipe is 14,637 feet; and the reservoir at Comiston is forty-four feet higher than the reservoir into which it delivers the water on the Castle Hill. *Query*, The number of Scottish pints which this pipe should deliver in a minute?

1. We have $d = \frac{5}{4} = 1{\cdot}25$ inches. The logarithm corresponding to this *d*, being nearly the mean between the logarithms corresponding to 1·2 and 1·3, is 2·49472.

2. We have $s = \frac{14637}{44}$ or 332·7. The logarithm corresponding to this in Table II. is had by taking proportional parts for the difference between the logarithms for $s = 330$ and $s = 340$, and is 1·18533.

3. From 2·49472
Take 1·18533

Remains 1·30939, the logarithm of 20·385 inches.

4. In column 3 of Table I. opposite to $d = 1{\cdot}2$ and $d = 1{\cdot}3$, are 0·3 and 0·31, of which the mean is 0·305 inches, the correction for viscidity.

5. Therefore the velocity in inches per second is 20·385 — 0·305, or 20·08.

6. To obtain the Scotish pints per minute (each containing 103·4 cubic inches), multiply the velocity by 60, and this product by 5^2, and this by 0·7854 (the area of a circle whose diameter is 1), and divide by 103·4. Or, by logarithms,

Add the log. of 20·08........................... 1·30276
log. of 60″........................... 1·77815
log. 5^2 or 25........................... 1·39794
log. of 0·7854........................... $\bar{1}{\cdot}89509$

4·37394
Subtract the log. of 103·4........................... 2·01451

Remains the log. of 228·8 pints..................... 2·35943

Example 2. The canal mentioned in the article RIVER, p. 270, was 18 feet broad at the surface, and 7 feet at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a mile. *Query*, The mean velocity?

1. The slant side of the canal corresponding to 4 feet deep and $5\frac{1}{2}$ projection, is 6·8 feet; therefore the border touched by the water is $6{\cdot}8 + 7 + 6{\cdot}8 = 20{\cdot}6$. The area is $4 \times \frac{18 + 7}{2} = 50$ square feet. Therefore $d = \frac{50}{20{\cdot}6} = 2{\cdot}427$ feet, or 29·124 inches. The logarithm corresponding to this in Table I. is 3·21113, and the correction for viscidity from the third column of the same table is 1·58.

2. The slope is one third of a foot in a mile, or one foot in three miles. Therefore *s* is 15840. The logarithm corresponding to this is 2·08280.

3. From 3·21113
Subtract 2·08280

Remains 1·12833 = log. of 13·438 inches.
Subtract for viscidity......... 1·58

Velocity per second......... 11·858

This velocity is considerably smaller than what was observed by Mr Watt. And indeed we observe, that in the very small declivities of rivers and canals, the formula is a little different. We have made several comparisons with a formula which is essentially the same with Du Buat's, and comes nearer in these cases. Instead of taking the hyperbolic logarithm of $\sqrt{\overline{s + 1{\cdot}6}}$, multiply its common logarithm by $2\frac{1}{4}$, or multiply it by 9, and divide the product by 4; and this process is vastly easier than taking the hyperbolic logarithm.

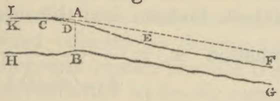
We have not however presumed to calculate tables on the authority of our own observations, thinking too respectfully of this gentleman's labours and observations. But this subject will ere long be fully established on a series of observations on canals of various dimensions and declivities, made by several eminent engineers during the execution of them. Fortunately the Chevalier du Buat's formula is chiefly founded on observations on small canals; and is therefore most accurate in works where it is most necessary, viz. in mill-courses, and other derivations for working machinery.

We now proceed to take notice of a few circumstances which deserve attention, in the construction of canals, in addition to those delivered in the article RIVER.

When a canal or aqueduct is brought off from a basin or larger stream, it ought always to be widened at the entry, if it is intended for drawing off a continued stream of water; for such a canal has a slope, without which it can have no current. Suppose it filled to a dead level to the farther end: take away the bar, and the water immediately begins to flow off at that end; but it is some time before any motion is perceived at the head of the canal, during all which time the motion of the water is augmenting in every part of the canal; consequently the slope is increasing in every part, this being the sole cause of its stream. When the water at the entry *begins* to move, the slope is scarcely sensible there; but it sensibly steepens every moment with the increase of velocity, which at last attains its maximum relative to the slope and dimensions of the whole canal; and this regulates the depth of water in every point down the stream. When all has attained a state of permanency, the slope at the entry *remains* much greater than in any other part of the canal; for this slope must be such as will produce a velocity sufficient for supplying its TRAIN. And it must be remembered, that the velocity which must be produced greatly exceeds the mean velocity corresponding to the train of the canal. Suppose that this is twenty-five inches: there must be a velocity of thirty inches at the surface, as appears by the table in the article RIVER, p. 273. This must be produced by a real fall at the entry.

In every other part the slope is sufficient if it merely serves to give the water (already in motion) force enough for overcoming the friction and other resistances. But at the entry the water is stagnant if in a basin, or it is moving past laterally if the aqueduct is derived from a river; and having no velocity whatever in the direction of the canal, it must derive it from its slope. The water therefore which has acquired a permanent form in such an aqueduct, must necessarily take that form which exactly performs the offices requisite in its different portions. The surface remains horizontal in the basin, as KC (fig. 1), till it comes near the entry of the canal AB, and there it acquires the

Fig. 1.



form of an undulated curve CD, and then the surface acquires an uniform slope EF, in the lower part of the canal, where the water is in train. If this is a drain, the discharge is much less than might be produced by the same bed if this sudden slope could be avoided. If it is to be navigated, having only a very gentle slope in its whole length, this sudden slope is a very great imperfection, both by diminishing the depth of water which might otherwise be obtained along the canal, and by rendering the passage of boats into the basin very difficult, and the coming out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the simple process of enlarging the entry. Suppose that the water could accelerate along the slopes of the canal, as a heavy body would do on a finely polished plane. If we now make the width of the entry in its different parts inversely proportional to the fictitious velocities in those parts, it is plain that the slope of the surface will be made parallel to that of the canal which is in train. This will require a form somewhat like a bell or speaking trumpet, as may easily be shown by a mathematical discussion. It would however be so much evasated at the basin as to occupy much room, and it would be very expensive to make such an excavation; but we may, at a very moderate expense of money and room, make the increase of velocity at the entry almost insensible. This should always be done, and it is not all expense; for if it be not done, the water will undermine the banks on each side, because it is moving very swiftly, and will make an excavation for itself, leaving all the mud in the canal below. We may observe this enlargement at the entry of all natural derivations from a basin or lake. It is a very instructive experiment to fill up this enlargement, continuing the parallel sides of the drain quite to the side of the lake. We shall immediately observe the water grow shallower in the drain, and its performance will diminish. Supposing the ditch carried on with parallel sides quite to the side of the basin, if we build two walls or dikes from the extremities of those sides, bending outwards with a proper curvature (and this will often be less costly than widening the drain), the discharge will be greatly increased. We have seen instances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing to the same cause. The tide of flood up the river produces a superficial slope opposite to that of the river, and this widens the mouth. This is most remarkable when the tides are high, and the river has little slope.

After this great fall at the entry of the canal, in which all the filaments are much accelerated, and the inferior ones most of all, things take a contrary turn. The water, by rubbing on the bottom and the sides, is retarded; and therefore the section must, from being shallow, become a little deeper, and the surface will be convex for some distance, till it comes into train. When this is established, the filaments nearest the bottom and side are moving slowest, and the surface, in the middle especially, retains the greatest velocity, gliding over the rest. The velocity in the canal, and the depth of the section, adjust themselves in such a manner that the difference between the surface of the basin and the surface of the uniform section of the canal corresponds exactly to the velocity. Thus, if this be observed to be two feet in a second, the difference of height will be $\frac{3}{16}$th of an inch.

All the practical questions that are of considerable importance respecting the motion of water in aqueducts, may be easily, though not elegantly, solved by means of the tables. But it is to be remembered, that these tables relate only to uniform motion, that is, to water that is in train, and where the velocity suffers no change by lengthening the conduit, provided the slope remain the same. It is much more difficult to determine what will be the velocity, &c. in a canal of which nothing is given but the form, and slope, and depth of the entry, without saying how deep the water runs in it. And it is here that the common doctrines of hydraulics are most in fault, and unable to teach us how deep the water will run in a canal, though the depth of the basin at the entry be perfectly known. Between the part of the canal which is in train and the basin, there is an interval where the water is in a state of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly difficult, even in a rectangular canal. It was one great aim of Du Buat's experiments to ascertain this by measuring accurately the depth of the water. But he found that when the slope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the slope was still less, the small fractions of an inch, by which he was to judge of the variations of depth, could not be measured with sufficient accuracy. It would be a most desirable point to determine the length of a canal, whose slope and other dimensions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entry, and the depth which will be maintained. Till this be done, the engineer cannot ascertain by a direct process what quantity of water will be drawn off from a reservoir by a given canal. But as yet this is out of our reach. Experiments however are in view which will promote the investigation.

But this and similar questions are of such importance that we cannot be said to have improved hydraulics unless we can give a tolerably precise answer. This we can do by a sort of retrograde process, proceeding on the principles of uniform motion established by the Chevalier du Buat. We may suppose a train maintained in the canal, and then examine whether this train *can* be produced by any fall that is possible at the entry. If it can, we may be certain that it is so produced, and our problem is solved.

We shall now point out the methods of answering some chief questions of this kind.

Quest. 1. Given the slope s and the breadth w of a canal, and the height H of the surface of the water in the basin above the bottom of the entry; to find the depth h and velocity V of the stream, and the quantity of water Q which is discharged.

The chief difficulty is to find the depth of the stream where it is in train. For this end, we may simplify the hydraulic theorem of uniform motion in the article River; making $\text{V} = \frac{\sqrt{\text{N}\,g\,d}}{\sqrt{\text{S}}}$, where g is the velocity (in inches) acquired in a second by falling, d is the hydraulic mean depth, and $\sqrt{\text{S}}$ stands for $\sqrt{s} - \text{L}\sqrt{s + 1\cdot6}$. N is a number to be fixed by experiment (see River), depending on the contraction or obstruction sustained at the entry of the canal, and it may in most common cases be taken $= 244$; so that $\sqrt{\text{N}\,g}$ may be somewhat less than 307. To find it, we may begin by taking for our depth of stream a quantity h, somewhat smaller than H the height of the surface of the basin above the bottom of the canal. With this depth, and the known width w of the canal, we can find the hydraulic depth d (see River, p. 265). Then with $\sqrt{d}$ and the slope find V by the table: make this $\text{V} = \frac{\sqrt{\text{N}\,g\,d}}{\sqrt{\text{S}}}$. This gives $\sqrt{\text{N}\,g} = \frac{\text{V}\sqrt{\text{S}}}{\sqrt{d}}$. This value of N g is sufficiently exact; for a small error of depth hardly affects the hydraulic mean depth.

After this preparation, the expression of the mean velocity in the canal will be $\frac{\sqrt{\mathrm{N}g}\sqrt{\frac{wh}{w+2h}}}{\sqrt{\mathrm{S}}}$. The height which will produce this velocity is $\frac{\mathrm{N}g}{2\mathrm{GS}}\left(\frac{wh}{w+2h}\right)$. Now this is the slope at the entry of the canal which produces the velocity that is afterwards maintained against the obstructions by the slope of the canal. It is therefore $=$ H — h. Hence we deduce

$$h = \frac{-\left[w\left(\frac{\mathrm{N}g}{2\mathrm{GS}}+1\right)-2\mathrm{H}\right]}{4}$$

$$+\frac{\sqrt{8\mathrm{H}w+\left[w\left(\frac{\mathrm{N}g}{2\mathrm{GS}}+1\right)-2\mathrm{H}\right]^2}}{4}.$$

If there be no contraction at the entry, $g = \mathrm{G}$ and $\frac{g}{2\mathrm{G}} = \frac{1}{2}$.

Having thus obtained the depth h of the stream, we obtain the quantity of water by combining this with the width w, and the velocity V.

But as this was but an approximation, it is necessary to examine whether the velocity V be possible. This is very easy. It must be produced by the fall H — h. We shall have no occasion for any correction of our first assumption, if h has not been extravagantly erroneous, because a small mistake in h produces almost the same variation in d. The test of accuracy however is, that h, together with the height which will produce the velocity V, must make up the whole height H. Assuming h too small, leaves H — h too great, and will give a small velocity V, which requires a small value of H — h. The error of H — h therefore is always greater than the error we have committed in our first assumption. Therefore when this error of H — h is but a trifle, such as one fourth of an inch, we may rest satisfied with our answer.

Perhaps the easiest process may be the following: Suppose the whole stream in train to have the depth H. The velocity V obtained for this depth and slope by the table requires a certain depth u. Make $\sqrt{\mathrm{H}+u} : \mathrm{H} = \mathrm{H} : h$, and h will be exceedingly near the truth. The reason is obvious.

Quest. 2. Given the discharge (or quantity to be furnished in a second) Q, the height H of the basin above the bottom of the canal, and the slope; to find the dimensions of the canal.

Let x and y be the depth and mean width. It is plain that the equation $\frac{\mathrm{Q}}{xy} = \sqrt{2\mathrm{G}}\sqrt{\mathrm{H}-x}$ will give a value of y in terms of x. Compare this with the value of y obtained from the equation $\frac{\mathrm{Q}}{xy} = \frac{\sqrt{\mathrm{N}g}}{\sqrt{\mathrm{S}}}\sqrt{\frac{xy}{y+2x}}$. This will give an equation containing only x and known quantities. But it will be very complicated, and we must have recourse to an approximation. This will be best understood in the form of an example.

Suppose the depth at the entry to be 18 inches, and the slope $\frac{1}{1000}$. Let 1200 cubic feet of water per minute be the quantity of water to be drawn off for working machinery, or any other purpose; and let the canal be supposed of the best form recommended in the article River, where the base of the sloping side is four thirds of the height.

The slightest consideration will show us, that if $\frac{\mathrm{V}^2}{744}$ be taken for the height producing the velocity, it cannot exceed three inches, nor be less than one. Suppose it two inches, and therefore the depth of the stream in the canal to be sixteen inches; find the mean width of the canal by the equation $w = \frac{\mathrm{Q}}{h(\sqrt{d}-0{\cdot}1)\left(\frac{307}{\sqrt{\mathrm{S}}}-0{\cdot}3\right)}$, in which Q is twenty cubic feet (the sixtieth part of 1200), $\sqrt{\mathrm{S}}$ is $= 28{\cdot}153 = \sqrt{1000} - \mathrm{L}\sqrt{1000+1{\cdot}6}$, and $h = 16$. This gives $w = 5{\cdot}52$ feet. The section $n = 7{\cdot}36$ feet, and $\mathrm{V} = 32{\cdot}6$ inches. This requires a fall of 1·52 inches instead of two inches. Take this from eighteen, and there remains 16·48, which we shall find not to differ one tenth of an inch from the exact depth which the water will acquire and maintain. We may therefore be satisfied with assuming 5·36 feet as the mean width, and 3·53 feet for the width at the bottom.

This approximation proceeds on the consideration, that when the width diminishes by a small quantity, and in the same proportion that the depth increases, the hydraulic mean depth remains the same, and therefore the velocity also remains, and the quantity discharged changes in the exact proportion of the section. Any minute error which may result from this supposition, may be corrected by increasing the fall producing the velocity, in the proportion of the first hydraulic mean depth to the mean depth corresponding to the new dimensions found for the canal. It will now become 1·53, and V will be 32·72, and the depth will be 16·47. The quantity discharged being divided by V, will give the section $= 7{\cdot}335$ feet, from which, and the new depth, we obtain 5·344 for the width.

This and the foregoing are the most common questions proposed to an engineer. We asserted with some confidence that few of the profession are able to answer them with tolerable precision. We cannot offend the professional gentlemen by this, when we inform them that the Academy of Sciences at Paris were occupied during several months with an examination of a plan proposed by M. de Parcieux, for bringing the waters of the Yvette into Paris, and after the most mature consideration, gave in a report of the quantity of water which M. de Parcieux's aqueduct would yield; and that their report has been found erroneous in the proportion of at least two to five; for the waters have been brought in, and exceed the report in this proportion. Indeed, long after giving in the report, M. Perronet, the most celebrated engineer in France, affirmed that the dimensions proposed were much greater than were necessary, and said that an aqueduct of five and a half feet wide and three and a half deep, with a slope of fifteen inches in a thousand fathoms, would have a velocity of twelve or thirteen inches per second, which would bring in all the water furnished by the proposed sources. The great diminution of expense occasioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near nineteen inches when it was three and a half feet deep. M. Perronet founded his computation on his own experience alone, acknowledging that he had no theory to instruct him. The work was carried no farther, it being found that the city could be supplied at a much smaller expense by steam-engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable. If M. Perronet's aqueduct be examined by our general formula, s will be found $= \frac{1}{4300}$, and $d = 18{\cdot}72$, from which we deduce the velocity $= 18\frac{2}{3}$, agreeing with the observation with astonishing precision.

The experiments at Turin by Michelotti on canals were very numerous, but complicated with many circumstances which would render the discussion too long for this place. When cleared of these circumstances, which we have done with scrupulous care, they are also abundantly conformable to our theory of the uniform motion of running waters. But to return to our subject.

Should it be required to bring off at once from the basin a mill-course having a determined velocity for driving an undershot wheel, the problem becomes easier, because the velocity and slope combined determine the hydraulic mean depth at once; and the depth of the stream will be had by means of the height which must be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be discharged, and the velocity and the depth at the entry, we can find the other dimensions of the channel; and the mean depth being found, we can determine the slope.

When the slope of a canal is very small, so that the depth of the uniform stream differs but a little from that at the entry, the quantity discharged is but small. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compensate for this diminution, and the quantity discharged may be smaller. Improbable as this may appear, it is not demonstrably false; and hence we see the propriety of the following question.

Question 3. Given the depth H at the entry of a rectangular canal, and also its width w; required the slope, depth, and velocity which will produce the greatest possible discharge.

Let x be the unknown depth of the stream. $H-x$ is the productive fall, and the velocity is $\sqrt{2\,G}\,\sqrt{H-x}$. This multiplied by $w\,x$ will give the quantity discharged. Therefore $w\,x\sqrt{2\,G}\,\sqrt{H-x}$ must be made a maximum. The common process for this will give the equation $2\,H=3\,x$, or $x=\frac{2}{3}H$. The mean velocity will be $\sqrt{2\,G}\sqrt{\frac{1}{3}H}$; the section will be $\frac{2}{3}\,w\,H$, and the discharge $=$ $\frac{2}{3}\sqrt{2\,G}\,w\,H\sqrt{\frac{1}{2}H}$, and $d=\frac{\frac{2}{3}\,w\,H}{w+\frac{4}{3}H}$. With these data the slope is easily had by the formula for uniform motion.

If the canal is of the trapezoidal form, the investigation is more troublesome, and requires the resolution of a cubic equation.

It may appear strange that increasing the slope of a canal beyond the quantity determined by this problem can diminish the quantity of water conveyed. But one of these two things must happen; either the motion will not acquire uniformity in such a canal for want of length, or the discharge must diminish. Supposing, however, that it could augment, we can judge how far this can go. Let us take the extreme case by making the canal vertical. In this case it becomes a simple weir or waste-board. Now the discharge of a waste-board is $\frac{2}{3}\sqrt{2\,G}\,w\left(h^{\frac{3}{2}}-(\frac{1}{2}\,h)^{\frac{3}{2}}\right)$. The maximum determined by the preceding problem is to that of the waste-board of the same dimensions as $H\sqrt{\frac{1}{3}H}:H^{\frac{3}{2}}-(\frac{1}{2}H)^{\frac{3}{2}}$, or as $H\sqrt{\frac{1}{3}H}:H\sqrt{H}-\frac{1}{2}H\sqrt{\frac{1}{2}H}=5773:6465$, nearly $=9:10$.

Having given the dimensions and slope of a canal, we can discover the relation between its expenditure and the time; or we can tell how much it will sink the surface of a pond in twenty-four hours, and the gradual progress of this effect; and this might be made the subject of a particular problem, but it is complicated and difficult. In cases where this is an interesting object, we may solve the question with sufficient accuracy, by calculating the expenditure at the beginning, supposing the basin kept full. Then, from the known area of the pond, we can tell in what time this expenditure will sink an inch; do the same on the supposition that the water is one third lower, and that it is two thirds lower (noticing the contraction of the surface of the pond occasioned by this abstraction of its waters). Thus we shall obtain three rates of diminution, from which we can easily deduce the desired relation between the expenditure and the time.

Aqueducts derived from a basin or river are commonly furnished with a sluice at the entry. This changes exceedingly the state of things. The slope of the canal may be precisely such as will maintain the mean velocity of the water which passes under the sluice; in which case the depth of the stream is equal to that of the sluice, and the velocity is produced at once by the head of water above it. But if the slope is less than this, the velocity of the issuing water is diminished, and the water must rise in the canal. This must check the efflux at the sluice, and the water will be as it were stagnant above what comes through below it. It is extremely difficult to determine at what precise slope the water will begin to check the efflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminishes by the obstructions. While the regorging which these obstructions occasion does not reach back to the sluice, the efflux is not affected by it. Even when it does reach to the sluice, there will be a less depth immediately behind it than farther down the canal, where it is in train; because the swift moving water which is next the bottom drags with it the regorged water which lies on it: but the canal must be rapid to make this difference of depth sensible. In ordinary canals, with moderate slopes and velocities, the velocity at the sluice may be safely taken as if it were that which corresponds to the difference of depths above and below the sluice, where both were in train.

Let therefore H be the depth above the sluice, and h the depth in the canal. Let e be the elevation of the sluice above the sole, and let b be its breadth. The discharge will be $e\,b\sqrt{H-h}\sqrt{2\,G}$ for the sluice, and $w\,h\frac{\sqrt{N\,g}}{\sqrt{S}}\sqrt{\frac{w\,h}{w+2\,h}}$ for the canal. These must be the same. This gives the equation $e\,b\sqrt{H-h}\sqrt{2\,G}=w\,h\frac{\sqrt{N\,g}}{\sqrt{S}}\sqrt{\frac{w\,h}{w+2\,h}}$, containing the solution of all the questions which can be proposed. The only uncertainty is in the quantity G, which expresses the velocity competent to the passage of the water through the orifice, circumstanced as it is, namely, subjected to contraction. This may be regulated by a proper form given to the entry into this orifice. The contraction may be almost annihilated by making the masonry of a cycloidal form on both sides, and also at the lower edge of the sluice-board, so as to give the orifice a form resembling fig. 5, D, in the article RIVER. If the sluice is thin in the face of a basin, the contraction will reduce 2 G to 296. If the sluice be as wide as the canal, 2 G will be nearly 500.

Question 4. Given the head of water in the basin H, the breadth b, and the elevation e of the sluice, and the breadth w and slope s of the canal, to find the depth h of the stream, the velocity, and the discharge.

We must (as in *Question* 2) make a first supposition for h, in order to find the proper value of d. Then the equation $e\,b\sqrt{H-h}\sqrt{2\,G}=w\,h\frac{\sqrt{N\,g\,d}}{\sqrt{S}}$ gives $h=\frac{G\,e^2\,b^2\,S}{w^2\,N\,g\,d}+\sqrt{\frac{G\,e^2\,b^2\,S\,H}{w^2\,N\,g\,d}+\left(\frac{G\,e^2\,b^2\,S}{w^2\,N\,g\,d}\right)^2}$. If this value shall differ considerably from the one which we assumed in order to begin the computation, make use of it for obtaining a new value of d, and repeat the operation. We shall rarely be obliged to perform a third operation.

The following is of frequent use.

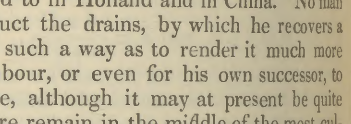
Question 5. Given the dimensions and the slope, with the velocity and discharge of a river in its ordinary state; required the area or section of the sluice which will raise the waters to a certain height, still allowing the same quantity of water to pass through. Such an operation may render the rivers navigable for small craft or rafts above the sluice.

The problem is reduced to the determination of the size of orifice which will discharge this water with a velocity competent to the height to which the river is to be raised; only we must take into consideration the velocity of the water above the sluice, considering it as produced by a fall which makes a part of the height productive of the whole velocity at the sluice. Therefore H, in our investigation, must consist of the height to which we mean to raise the waters, and the height which will produce the velocity with which the waters approach the sluice; *h*, or the depth of the stream, is the ordinary depth of the river. Then (using the former symbols) we have $e\,b = \frac{w\,h\,\sqrt{\mathrm{N}\,g\,d}}{\sqrt{2\,\mathrm{GS}\,(\mathrm{H}-h)}} = \frac{\mathrm{Q}}{\sqrt{2\,\mathrm{G}\,(\mathrm{H}-h)}}$.

If the area of the sluice is known, and we would learn the height to which it will raise the river, we have $\mathrm{H}-h = \frac{\mathrm{Q}^2}{2\,\mathrm{G}\,e^2 b^2}$, for the expression of the rise of the water above its ordinary level. But from this we must take the height which would produce the velocity of the river; so that if the sluice were as wide as the river, and were raised to the ordinary surface of the water, $\frac{\mathrm{Q}^2}{2\,\mathrm{G}\,e^2 b^2}$, which expresses the height that produces the velocity under the sluice, must be equal to the depth of the river, and $\mathrm{H}-h$ will be $=0$.

The performance of aqueduct drains is a very important object, and merits our attention in this place. While the art of managing waters, and of conducting them so as to answer our demands, renders us very important service, by embellishing our habitations, or promoting our commercial intercourse, the art of draining creates as it were new riches, fertilizing tracts of bog or marsh, which were not only useless, but hurtful by their unwholesome exhalations, and converting them into rich pastures and gay meadows. A wild country, occupied by marshes which are inaccessible to herds or flocks, and serve only for the haunts of water-fowls, or the retreat of a few poor fishermen, when once it is freed from the waters in which it is drowned, opens its lap to receive the most precious seeds, is soon clothed in the richest garb, gives life and abundance to numerous herds, and never fails to become the delight of the industrious cultivator who has enfranchised it, and is attached to it by the labour which it cost him. In return, it procures him abundance, and supplies him with the means of daily augmenting its fertility. No species of agriculture exhibits such long-continued and progressive improvement. New families flock to the spot, and there multiply; and there nature seems the more eager to repay their labours, in proportion as she has been obliged, against her will, to keep her treasures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, especially to the southward, are still covered to a great extent with marshes and lakes; and they would long remain in this condition, if population, daily making new advances, did not increase industry, by multiplying the cultivating hands, at the same time that it increases their wants. The Author of this beautiful world has at the beginning formed the great masses of mountain, has scooped out the dales and sloping hills, has traced out the courses, and even formed the beds, of the rivers; but he has left to man the care of making his place of abode, and the field which must feed him, dry and comfortable. For this task is not beyond his powers, as the others are. Nay, by having this given to him in charge, he is richly repaid for his labour by the very state in which he finds those countries into which he penetrates for the first time. Being covered with lakes and forests, the juices of the soil are kept for him as it were in reserve. The air, the burning heat of the sun, and the continual washing of rains, would have combined to expend and dissipate their vegetative powers, had the fields been exposed in the same degree to their action as the inhabited and cultivated countries, the most fertile moulds of which are long since lodged in the bottom of the ocean. All this would have been completely lost through the whole extent of South America, had it not been protected by the forests which man must cut down, by the rank herbage which he must burn, and by the marsh and bog which he must destroy by draining. Let not ungrateful man complain of this. It is his duty to take on himself the task of opening up treasures, preserved on purpose for him with so much judgment and care. If he has discernment and sensibility, he will even thank the Author of all good, who has thus husbanded them for his use. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly snatching at present any partial good, and by picking out what is most easily procured, regardless of him who is to come afterwards to uncover and extract the remaining riches of the ground. A wise administration of such a country will think it their duty to leave a just share of this inheritance to their descendants, who are entitled to expect it as the last legatees. National plans of cultivation should be formed on this principle, that the steps taken by the present cultivators for realizing part of the riches of the infant country shall not obstruct the works which will afterwards be necessary for obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct the drains, by which he recovers a piece of marsh, in such a way as to render it much more difficult for a neighbour, or even for his own successor, to drain another piece, although it may at present be quite inaccessible. There remain in the middle of the most cultivated countries many marshes, which industry has not yet attempted to drain, and where the legislature has not been at pains to prevent many little abuses which have produced elevations in the beds of rivers, and rendered the complete draining of some spots impossible. Administration should attend to such things, because their consequences are great. The sciences and arts, by which alone these difficult and costly jobs can be performed, should be protected, encouraged, and cherished. It is only from science that we can obtain principles to direct these arts. The problem of draining canals is one of the most important, and yet has hardly ever occupied the attention of the hydraulic speculatist. We apprehend that the Chevalier du Buat's theory will throw great light on it; and regret that the very limited condition of our present work will hardly afford room for a slight sketch of what may be done on the subject. We shall, however, attempt it by a general problem, which will involve most of the chief circumstances which occur in works of that kind.

Fig. 2.



Quest. 6. Let the hollow ground A (fig. 2) be inundated by rains or springs, and have no outlet but the canal AB, by which it discharges its water into the neighbouring river BCDE, and let its surface be nearly on a level with that of the river at B. It can only drain when the river sinks in the droughts of summer; and even if it could then drain completely, the put l marsh would only be an infecting neighbour. It ma be proposed to drain it by one or more canals, and it is r uired to determine their lengths and other dimensions, so a to produce the best effects. It is evident that there are any circumstances to determine the choice, and many con tions to be attended to.

I the canals AC, AD, AE, are respectively equal to the roportions BC, BD, BE, of the river, and have the sam slopes, they will have the same discharge; but they are ot for this reason equivalent. The long canal AE may rain the marsh completely, while the short one AC will nly do it in part; because the difference of level betwe A and C is but inconsiderable. Also the freshes of the ver may totally obstruct the operation of AC, while the nal AE cannot be hurt by them, E being so much lowe than C. Therefore the canal must be carried so far dow the river, that no freshes there shall ever raise the wate in the canal so high as to reduce the slope in the uppe part of it to such a level that the current shall not be s ficient to carry off the ordinary produce of water in the arsh.

S l the problem is indeterminate, admitting many solution This requisite discharge may be accomplished by a shor out wide canal, or by a longer and narrower. Let us first e what solution can be made, so as to accomplish our rpose in the most economical manner, that is, by mea of the smallest equation. We shall give the solution in th form of an example.

S pose that the daily produce of rains and springs raises the ater $1\frac{1}{2}$ inch on an area of a square league, which give about 120,000 cubic fathoms of water. Let the bottom f the basin be three feet below the surface of the fresh in the river at B in winter. Let the slope of the rive e two inches in 100 fathoms, or $\frac{1}{1600}$, and the canal six f t deep.

T canal being supposed nearly parallel to the river, it mu be at least 1800 fathoms long before it can be admitt into the river, otherwise the bottom of the bog will be lo er than the mouth of the canal; and even then a hunc d or two more fathoms added to this will give it so little ope, that an immense breadth will be necessary to mak he discharge with so small a velocity. On the other hand f the slope of the canal be made equal to that of the river n extravagant length will be necessary before its admissi into the river, and many obstacles may then intervene and even then it must have a breadth of thirteen feet, may easily be calculated by the general hydraulic theor n. By receding from each of these extremes, we shall minish the expense of excavation. Therefore,

L x and y be the breadth and length, and h the depth (six et), of the canal. Let q be the depth of the bog below t surface of the river, opposite to the basin, D the disch ge in a second, and $\frac{1}{a}$ the slope of the river. We must ake $h\,x\,y$ a minimum, or $x\,d\,y + y\,d\,x = 0$.

Th general formula gives the velocity

$$V = \frac{\sqrt{n\,g}\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{s} - \mathrm{L}\,\sqrt{s + 1{\cdot}6}} - 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1).$$

This would give and y; but the logarithmic term renders it very comp cated. We may make use of the simple form

$$V = \frac{\sqrt{\mathrm{N}\,g\,d}}{\sqrt{\mathrm{S}}},$$

making $\sqrt{\mathrm{N}\,g}$ nearly 296. This will be suffic ntly exact for all cases which do not deviate far from this, cause the velocities are very nearly in the subduplica ratio of the slopes.

T ntroduce these data into the equation, recollect that $V = \frac{\mathrm{D}}{x}$, $d = \frac{h\,x}{x + 2\,h}$. As to S, recollect that the canal being supposed of nearly equal length with the river, $\frac{y}{a}$ will express the whole differenee of height, and $\frac{y}{a} - q$ is the difference of height for the canal. This quantity being divided by y, gives the value of $\frac{1}{\mathrm{S}} = \frac{\frac{y}{a} - q}{y}$. Therefore the equation for the canal becomes

$$\frac{\mathrm{D}}{h\,x} = \sqrt{\mathrm{N}\,g}\,\sqrt{\frac{h\,x}{x + 2\,h}}\,\sqrt{\frac{\frac{y}{a} - q}{y}}.$$

Hence we deduce

$$y = \frac{\mathrm{N}\,g\,q\,h^3\,x^3}{\frac{\mathrm{N}\,g\,h^3\,x^3}{a} - \mathrm{D}^2(x + 2\,h)},$$

and

$$dy = \frac{3\,\mathrm{N}\,g\,q\,h^3\,x^2\,d\,x}{\frac{\mathrm{N}\,g\,h^3\,x^3}{a} - \mathrm{D}^2\,(x + 2\,h)} - \frac{\mathrm{N}\,g\,q\,h^3\,x^3\,d\,x\left(\frac{3\mathrm{N}\,g\,h^3\,x^3}{a} - \mathrm{D}^2\right)}{\left[\frac{\mathrm{N}\,g\,h^3\,x^3}{a} - \mathrm{D}^2\,(x + 2\,h)\right]^2}.$$

If we substitute these values in the equation $y\,d\,x + x\,d\,y = 0$, and reduce it, we obtain finally

$$\frac{\mathrm{N}\,g\,h^3\,x^3}{a\,\mathrm{D}^2} - 3\,x = 8\,h.$$

If we resolve this equation by making $\mathrm{N}\,g = (296)^2$, or 87616 inches, $h = 72$, $\frac{1}{a} = \frac{1}{3600}$, and $\mathrm{D} = 518400$, we obtain $x = 392$ inches, or 32 feet 8 inches, and $\frac{\mathrm{D}}{h\,x}$, or $V = 18{\cdot}36$ inches. Now putting these values in the exact formula for the velocity, we obtain the slope of the canal, which is $\frac{1}{11664}$, nearly 0·62 inches in 100 fathoms.

Let l be the length of the canal in fathoms. As the river has two inches fall in 100 fathoms, the whole fall is $\frac{2\,l}{100}$, and that of the canal is $\frac{0{\cdot}62\,l}{100}$. The difference of these two must be three feet, which is the difference between the river and the entry of the canal. We have therefore $\left(\frac{2 - 0{\cdot}62}{100}\right) l = 36$ inches. Hence $l = 2604$ fathoms; and this multiplied by the section of the canal gives 14,177 cubic fathoms of earth to be removed.

This may surely be done, in most cases, for eight shillings each cubic fathom, which does not amount to L.6000, a very moderate sum for completely draining nine square miles of country.

In order to judge of the importance of this problem, we have added two other canals, one longer and the other shorter, having their widths and slopes so adjusted as to insure the same performance.

Width. Feet.	Velocity, Inches.	Slope.	Length.	Excavation.
42	14·28	$\frac{1}{18988}$	2221	15547
$32\frac{2}{3}$	18·36	$\frac{1}{11664}$	2604	14177
21	28·57	$\frac{1}{4781}$	7381	15833

We have considered this important problem in its most simple state. If the basin is far from the river, so that the drains are not nearly parallel to it, and therefore have less slope attainable in their course, it is more difficult. Perhaps the best method is to try two very extreme cases and a middle one, and then a fourth, nearer to that extreme which differs least from the middle one in the quantity of excavation. This will point out on which side the minimum of excavation lies, and also the law by which it diminishes and afterwards increases. Then draw a line, on which set off from one end the lengths of the canals. At each length erect an ordinate representing the excavation, and draw a regular curve through the extremities of the ordinates. From that point of the curve which is nearest to the base line, draw another ordinate to the base. This will point out the best length of the canal with sufficient accuracy. The length will determine the slope, and this will give the width, by means of the general theorem. These draining canals must always come off from the basin with evasated entries. This will prevent the loss of much fall at the entry.

Two canals may sometimes be necessary. In this case expense may frequently be saved, by making one canal flow into the other. This however must be at such a distance from the basin, that the swell produced in the other by this addition may not reach back to the immediate neighbourhood of the basin, otherwise it would impede the performance of both. For this purpose, recourse must be had to Problem III. p. 283, of the article River. We must here observe, that in this respect canals differ exceedingly from rivers: rivers enlarge their beds, so as always to convey every increase of waters; but a canal may be gorged through its whole length, and will then greatly diminish its discharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted into it, their junction must be so far from the basin that the swell occasioned by raising its waters nearly $\frac{1}{2}$ more (viz. in the subduplicate ratio of 1 to 2) may not reach back to the basin.

This observation points out another method of economy. Instead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper distance from the basin. But the lower extremity will now be too shallow to convey the waters of both, therefore raise its banks by using the earth taken from its bed, which must at any rate be disposed of. Thus the waters will be conveyed, and the expense, even of the lower part of the long canal, will scarcely be increased.

These observations must suffice for an account of the management of open canals; and we proceed to the consideration of the conduct of water in pipes.

This is much more simple and regular, and the general theorem requires very trifling modifications for adapting it to the cases or questions that occur in the practice of the civil engineer. Pipes are always made round, and therefore d is always $\frac{1}{4}$th of the diameter. The velocity of water in a pipe which is in train, is $V = \frac{307\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{s} - \mathrm{L}\,\sqrt{s + 1{\cdot}6}} - 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1)$, or $= (\sqrt{d} - 0{\cdot}1)\left(\frac{307}{\sqrt{s} - \mathrm{L}\,\sqrt{s + 1{\cdot}6}} - 0{\cdot}3\right)$.

The chief questions are the following.

Quest. 1. Given the height H of the reservoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water discharged in a second.

Let L be the length, and h the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obstructions. This may be expressed in terms of the velocity by $\frac{V^2}{2G}$, G denoting the acceleration of gravity corresponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-shaped funnel or otherwise, 2G may be assumed as = 500 inches, or 42 feet, according as we measure the velocity in inches or feet. The slope is $\frac{1}{s} = \frac{H - \frac{V^2}{2G}}{L}$, which must be put into the general formula. This would make it very complicated. We may simplify it by the consideration that the velocity is very small in comparison of that arising from the height H; consequently h is very small. Also, in the same pipe, the resistances are nearly in the duplicate ratio of the velocities when these are small, and when they differ little among themselves. Therefore make $s = \frac{L}{h}$, taking h by guess, a very little less than H. Then compute the mean velocity v corresponding to these data, or take it from the table. If $h + \frac{v^2}{2G}$ be $= H$, we have found the mean velocity $V = v$. If not, make the following proportion.

$h : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G}$, which is the same with this,

$h + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{h + \frac{v^2}{2G}} = \frac{v^2 H}{\frac{2Gh + v^2}{2G}}$

$= \frac{v^2 \cdot 2GH}{v^2 + 2Gh}$.

If the pipe has any bendings, they must be calculated for in the manner mentioned in the article River; and the head of water necessary for overcoming this additional resistance being called $\frac{V^2}{m}$, the last proportion must be changed for

$$h + v^2\left(\frac{1}{2G} + \frac{1}{m}\right) : v^2 = H : V^2.$$

Quest. 2. Given the height of the reservoir, the length of the pipe, and the quantity of water which is to be drawn off in a second, to find the diameter of the pipe which will draw it off.

Let d be considered as $= \frac{1}{4}$th of the diameter, and let $1 : c$ represent the ratio of the diameter of a circle to its circumference. The section of the pipe is $4cd^2$. Let the quantity of water per second be Q; then $\frac{Q}{4cd^2}$ is the mean velocity. Divide the length of the pipe by the height of the reservoir above the place of delivery, diminished by a very small quantity, and call the quotient s. Consider this as the slope of the conduit; the general formula now becomes

$$\frac{Q}{4cd^2} = \frac{307\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{s} - \mathrm{L}\,\sqrt{s + 1{\cdot}6}} - 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1), \text{ or}$$

$$\frac{Q}{4cd^2} = \frac{(307\,(\sqrt{d} - 0{\cdot}1)}{\sqrt{S}} - 0{\cdot}3\,(\sqrt{d} - 0{\cdot}1).$$

We may neglect the last term in every case of civil practice, and also the small quantity 0·1. This gives the very simple formula

$$\frac{Q}{4cd^2} = \frac{307\sqrt{d}}{\sqrt{S}},$$

from which we readily deduce

$$d = \overline{\frac{Q\sqrt{S}}{4c \times 307}}\Big|^{\frac{2}{5}} = \overline{\frac{Q\sqrt{S}}{3858}}\Big|^{\frac{2}{5}}$$

This process gives the diameter somewhat too small. But we easily rectify this error by computing the quantity delivered by the pipe, which will differ a little from the quantity proposed. Then observing, by this equation, that two pipes having the same length and the same slope give quantities of water, of which the squares are nearly as the fifth powers of the diameter, we form a new diameter in this proportion, which will be almost perfectly exact.

It may be observed that the height assumed for determining the slope in these two questions, will seldom differ more than an inch or two from the whole height of the reservoir above the place of delivery; for in conduits of a few hundred feet long, the velocity seldom exceeds four feet per second, which requires only a head of three inches.

As no inconvenience worth minding results from making the pipes a tenth of an inch or so wider than is barely sufficient, and as this generally is more than the error arising from even a very erroneous assumption of *h*, the answer first obtained may be augmented by one or two tenths of an inch, and then we may be confident that our conduit will draw off the intended quantity of water.

We presume that every person who assumes the name of engineer knows how to reduce the quantity of water measured in gallons, pints, or other denominations, to cubic inches, and can calculate the gallons, &c. furnished by a pipe of known diameter, moving with a velocity that is measured in inches per second. We further suppose that all care is taken in the construction of the conduit, to avoid obstructions occasioned by lumps of solder hanging in the inside of the pipes; and particularly that all the cocks and plugs by the way have waterways equal to the section of the pipe. Undertakers are most tempted to fail here, by making the cocks too small, because large cocks are very costly; but the employer should be scrupulously attentive to this, because a simple contraction of this kind may be the throwing away of many hundred pounds in a wide pipe, which yields no more water than can pass through the small cock.

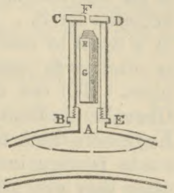
The chief obstructions arise from the deposition of sand or mud in the lower parts of pipes, or the collection of air in the upper parts of their bendings. The velocity being always very moderate, such depositions of heavy matters are unavoidable. The utmost care should therefore be taken to have the water freed from all such things at its entry by proper filtration; and there ought to be cleansing plugs at the lower parts of the bendings, or rather a very little way beyond them. When these are opened, the water issues with greater velocity, and carries the depositions with it.

It is much more difficult to get rid of the air which chokes the pipes by lodging in their upper parts. The air is sometimes taken in along with the water at the reservoir, when the entry of the pipe is too near the surface. This should be carefully avoided, and it costs no trouble to do so. If the entry of the pipe is two feet under the surface, no air can ever get in. Floats should be placed above the entries, having lids hanging from them, which will shut the pipe before the water runs too low.

But air is also disengaged from spring-water by merely passing along the pipe. When pipes are supplied by an engine, air is very often drawn in by the pumps in a disengaged state. It is also disengaged from its state of chemical union when the pumps have a suction-pipe of ten or twelve feet, which is very common. In whatever way it is introduced, it collects in all the upper parts of bendings, and chokes the passage, so that sometimes not a drop of water is delivered. Our cocks should be placed there, which should be opened frequently by persons who have this in charge. Desaguliers describes a contrivance to be placed on all such eminences, which does this of itself. It is a pipe with a cock, terminating in a small cistern. The key of the cock has a hollow ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this discharger, fills the cistern, raises the ball, and thus shuts the cock. But when the bend of the main contains air, it rises into the cistern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens and lets out the air, and the cistern again filling with water, the ball rises, and the cock is again shut.

A very neat contrivance for this purpose was invented by the late Professor Russell of Edinburgh. The cylindrical pipe BCDE (fig. 3), at the upper end of a bending of the main, is screwed on, the upper end of which is a flat plate perforated with a small hole F. This pipe contains a hollow copper cylinder G, to the upper part of which is fastened a piece of soft leather H. When there is air in the pipe, it comes out by the hole A, and occupies the discharger, and then escapes through the hole F. The water follows, and, rising in the discharger, lifts up the hollow cylinder G, causing the leather H to apply itself to the plate CD, and shut the hole. Thus the air is discharged without the smallest loss of water.

Fig. 3.



It is of the most material consequence that there be no contraction in any part of a conduit. This is evident; but it is also prudent to avoid all unnecessary enlargements. For when the conduit is full of water moving along it, the velocity in every section is inversely proportional to the area of the section: it is therefore diminished wherever the pipe is enlarged; but it must again be increased where the pipe contracts. This cannot be without expending force in the acceleration, which consumes part of the impelling power, whether this be a head of water, or the force of an engine. See what is said on this subject in the article Pump. Nothing is gained by any enlargement; and every contraction, by requiring an augmentation of velocity, employs a part of the impelling force precisely equal to the weight of a column of water whose base is the contracted passage, and whose height is the fall which would produce a velocity equal to this augmentation. This point seems to have been quite overlooked by engineers of the first eminence, and has in many instances greatly diminished the performance of their best works. It is no less detrimental in open canals, because at every contraction a small fall is required for restoring the velocity lost in the enlargement of the canal, by which the general slope and velocity are diminished. Another point which must be attended to in the conducting of water is, that the motion should not be subsultory, but continuous. When the water is to be driven along a main by the strokes of a reciprocating engine, it should be forced into an air-box, the spring of which may preserve it in motion along the whole subsequent main. If the water is brought to rest at every successive stroke of the piston, the whole mass must again be put in motion through the whole length of the main. This requires the same useless expenditure of power as to communicate this motion to as much dead matter; and this is over and above the force which may be necessary for raising the water to a certain height, which is the only circumstance that enters into the calculation of the power of the pump-engine.

An air-box removes this imperfection, because it keeps up the motion during the returning stroke of the piston. The compression of the air by the active stroke of the piston must be such as to continue the impulse in opposition to the contrary pressure of the water (if it is to be raised to some height), and in opposition to the friction or other resistances which arise from the motion that the water really acquires. Indeed a very considerable force is also employed here in changing the motion of the water, which is forced out of the capacious air-box into the narrow pipe; and when this change of motion is not judiciously managed, the expenditure of power may be as great as if all were brought to rest and again put in motion. It may even be greater, by causing the water to move in the opposite direction to its former motion. Of such consequence is it to have all these circumstances scientifically considered. It is in such particulars, unheeded by the ordinary herd of engineers or pump-makers, that the superiority of an intelligent practitioner is to be seen.

Another material point in the conduct of water in pipes is the distribution of it to the different persons who have occasion for it. This is rarely done from the rising main. It is usual to send the whole into a cistern, from which it is afterwards conducted to different places in separate pipes. Till the discovery of the general theorem by the Chevalier du Buat, this has been done with great inaccuracy. Engineers think that the different purchasers from water-works receive in proportion to their respective bargains when they give them pipes whose areas are proportional to these payments; but we now see that when these pipes are of any considerable length, the waters of a larger pipe run with a greater velocity than those of a smaller pipe having the same slope. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half such pipes or more; because the squares of the discharges are very nearly as the fifth powers of the diameters. This point ought therefore to be carefully considered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Perhaps the most unexceptionable method would be to make a double distribution. Let the water be first let off in its proper proportions into a second series of small cisterns, and let each have a pipe which will convey the whole water that is discharged into it. The first distribution may be made entirely by pipes of one inch in diameter; this would leave nothing to the calculation of the distributor, for every man would pay in proportion to the number of such pipes which runs into his own cistern.

In many cases, however, water is distributed by pipes derived from a main; and here another circumstance comes into action. When water is passing along a pipe, its pressure on the sides of the pipe is diminished by its velocity; and if a pipe is now derived from it, the quantity drawn off is also diminished in the subduplicate ratio of the pressures. If the pressure is reduced to one fourth, one ninth, one sixteenth, &c. the discharge from the lateral pipe is reduced to one half, one third, one fourth, &c. It is therefore of great importance to determine what this diminution of pressure is which arises from the motion along the main.

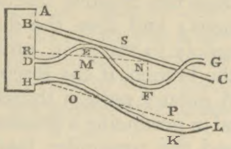
It is plain, that if the water suffered no resistance in the main, its velocity would be that with which it entered, and it would pass along without exerting any pressure. If the pipe were shut at the end, the pressure on the sides would be the full pressure of the head of water. If the head of water remain the same, and the end of the tube be contracted, but not stopped entirely, the velocity in the pipe is diminished. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we must employ the pressure of a piston, or of a head of water. This is propagated through the fluid, and thus a pressure is immediately excited on the sides of the pipe. New obstructions of any kind, arising from friction or any other cause, produce a diminution of velocity in the pipe: but when the natural velocity is checked, the particles re-act on what obstructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The resistance therefore which we thus ascribe to friction, produces the same lateral pressure which a contraction of the orifice, which equally diminishes the velocity in the pipe, would do. Indeed this is demonstrable from any distinct notions that we can form of these obstructions. They proceed from the want of perfect smoothness, which obliges the particles next the sides to move in undulated lines. This excites transverse forces in the same manner as any constrained curvilineal motion. A particle in its undulated path tends to escape from it, and acts on the lateral particles in the same manner that it would do if moving singly in a capillary tube having the same undulations; it would press on the concave side of every such undulation. Thus a pressure is exerted among the particles, which is propagated to the sides of the pipe; or the diminution of velocity may arise from a viscidity or want of perfect fluidity. This obliges the particle immediately pressed to drag along with it another particle which is withheld by adhesion to the sides. This requires additional pressure from a piston, or an additional head of water; and this pressure also is propagated to the sides of the pipe.

Hence it should follow, that the pressure which water in motion exerts on the sides of its conduit is equal to that which is competent to the head of water which impels it into the pipe, diminished by the head of water competent to the actual velocity with which it moves along the pipe. Let H represent the head of water which impels it into the entry of the pipe, and h the head which would produce the actual velocity; then $H - h$ is the column which would produce the pressure exerted on its sides.

This is abundantly verified by very simple experiments. Let an upright pipe be inserted into the side of the main pipe. When the water runs out by the mouth of the main, it will rise in this branch till the weight of the column balances the pressure that supports it; and if we then ascertain the velocity of the issuing water by means of the quantity discharged, and compute the head or height necessary for producing this velocity, and subtract this from the height of water above the entry of the main, we shall find the height in the branch precisely equal to their difference. Our readers may see this by examining the experiments related by Gravesande, and still better by examining the experiments related by Bossut, which are detailed with great minuteness. The results corresponded accurately with this proposition. The experiments indeed were not heights of water supported by this pressure, but water expelled by it through the same orifice. Indeed the truth of the proposition appears in every way we can consider the motion of water. And as it is of the first importance in the practice of conducting water (for reasons which will presently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminished in the proportion of the length of the oblique column to its vertical height, or its weight multiplied by the fraction $\frac{1}{s}$, which expresses the slope) is in equilibrio with the obstructions; and therefore it exerts no pressure on the pipe but what arises from its weight alone. Any part of it would continue to slide down the inclined plane with a constant velocity, though detached from what follows it. It therefore derives no pressure from the head of water which impelled it into the pipe. The same must be said of a horizontal pipe infinitely smooth, or opposing no resistance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe opposes an obstruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it; and this additional pressure is propagated along the pipe, where it is balanced by the actual resistance, and therefore excites a *quaquaversum* pressure on the pipe. In short, whatever part of the head of water in the reservoir, or of the pressure which impels it along the tube, is not employed in producing velocity, is employed in acting against some obstruction, and excites, by the re-action of this obstruction, an equal pressure on the tube. The rule therefore is general, but is subject to some modifications which deserve our attention.

In the simply inclined pipe BC (fig. 4), the pressure on any point S is equal to that of the head of water AB which im-

Fig 4.



pel the water into the pipe, wanting or *minus* that of the head of water which would communicate to the velocity with which it actually moves. This we shall call x, and consider it as the weight of a column of water whose length also is x. In like manner H may be the column AB which impels the water into the pipe, and would communicate a certain velocity; and h may represent the column which would communicate the actual velocity. We have therefore $x = \text{H} - h$.

In the pipe HIKL, the pressure at the point I is $\text{AH} - h - \text{IO} = \text{H} - h - \text{IO}$; and the pressure at K is $\text{H} - h + \text{PK}$.

And in the pipe DEFG, the pressure on E is $= \text{AR} - h - \text{EM} = \text{H} - h - \text{EM}$; and the pressure at F is $\text{H} - h + \text{FN}$.

We must carefully distinguish this pressure on any square inch of the pipe, from the obstruction or resistance which that inch actually exerts, and which is part of the cause of the pressure. The pressure, by the laws of hydrostatics, is the same with that exerted on the water by a square inch of the piston or forcing head of water. This must balance the united obstructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an enclosed pipe. Whatever be the inclination of a pipe, and the velocity of the water in it, there is a certain part of this resistance which may not be balanced by the tendency which the water has to slide along it, provided the pipe be long enough; or if the pipe is too short, the tendency down the pipe may more than balance all the resistances that obtain below. In the first case, this overplus must be balanced by an additional head of water; and in the latter case the pipe is not in train, and the water will accelerate. There is something in the mechanism of these motions which makes a certain length of pipe necessary for bringing it into train; a certain portion of the surface which acts in concert in obstructing the motion. We do not completely understand this circumstance, but we can form a pretty distinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obstruction but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films glide within those around them, somewhat like the sliding tubes of a spy-glass when we draw it out by taking hold of the end of the innermost. Thus the second film passes beyond the first and outermost, and becomes the outermost, and rubs along the tube. The third does the same in its turn; and thus the central filaments come at last to the outside, and all sustain their greatest possible obstruction. When this is accomplished the pipe is in train. This requires a certain length, which we cannot determine by theory. We see however that pipes of greater diameter must require a greater length, and that in a proportion which is probably that of the number of filaments, or the square of the diameter. Du Buat found this supposition agree well enough with his experiments. A pipe of one inch in diameter sustained no change of velocity by gradually shortening it till he reduced it to six feet and then it discharged a little more water. A pipe of two inches diameter gave a sensible augmentation of velocity when shortened to twenty-five feet. He therefore says that the square of the diameter in inches, multiplied by seventy-two, will express, in inches, the length necessary for putting any pipe in train.

The resistance exerted by a square inch of the pipe makes but a small part of the pressure which the whole resistances occasion to be exerted there before they can be overcome. The resistance may be represented by $\frac{d}{s}$, where d is the hydraulic depth (one fourth of the diameter), and s the length of a column whose vertical height is one inch, and it is the relative weight of a column of water whose base is a square inch, and height is d. For the resistance of any length s of pipe which is in train is equal to the tendency of the water to slide down (being balanced by it); that is, is equal to the weight of this column multiplied by $\frac{1}{s}$. The magnitude of this column is had by multiplying its length by its section. The section is the product of the border b, or circumference multiplied by the mean depth d, or it is bd. This multiplied by the length is bds; and this multiplied by the slope $\frac{1}{s}$ is bd, the relative weight of the column whose length is s. The relative weight of one inch is therefore $\frac{bd}{s}$; and this is in equilibrio with the resistance of a ring of the pipe one inch broad. This, when unfolded, is a parallelogram b inches in length. One inch of this therefore is $\frac{d}{s}$, the relative weight of a column of water having d for its height and a square inch for its base. Suppose the pipe four inches in diameter, and the slope $= 253$, the resistance is one grain, for an inch of water weighs 253 grains.

This knowledge of the pressure of water in motion is of great importance. In the management of rivers and canals it instructs us concerning the damages which they produce in their beds by tearing up the soil: it informs us of the strength which we must give to the banks, but it is of more consequence in the management of close conduits. By this we must regulate the strength of our pipes; by this also we must ascertain the quantities of water which may be drawn off by lateral branches from any main conduit.

With respect to the first of these objects, where security is our sole concern, it is proper to consider the pressure in the most unfavourable circumstances, viz. when the end of the main is shut. The case is not unfrequent. Nay, when the water is in motion, its velocity in a conduit seldom exceeds a very few feet in a second. Eight feet per second requires only one foot of water to produce it. We should therefore estimate the strain on all conduits by the whole height of the reservoir.

In order to adjust the strength of a pipe to the strain, we may conceive it as consisting of two half cylinders of insuperable strength joined along the two seams, where the strength is the same with the ordinary strength of the materials of which it is made. The inside pressure tends to burst the pipe by tearing open these seams; and each of these two seams is equal to the weight of a column of water whose height is the depth of the seam below the surface of the reservoir, and whose base is an inch broad and a diameter of the pipe in length. This follows from the common principles of hydrostatics.

Suppose the pipe to be of lead, one foot in diameter and 100 feet under the surface of the reservoir. Water weighs $62\frac{1}{2}$ pounds per foot. The base of our column is therefore $\frac{1}{12}$th of a foot, and the tendency to burst the pipe is $100 \times 62\frac{1}{2} \times \frac{1}{12} = \frac{6250}{12} = 521$ pounds nearly. Therefore an inch of one seam is strained by $260\frac{1}{2}$ pounds. A rod of lead one inch square is pulled asunder by 860 pounds (see STRENGTH OF MATERIALS). Therefore, if the thickness of the seam is $= \frac{260}{860}$ inches, or one third of an inch, it will just withstand this strain. But we must make it much stronger than this, especially if the pipe leads from an engine which sends the water along it by starts. Belidor and Desaguliers have given tables of the thickness and weights of pipes which experience has found sufficient for the different materials and depths. Desaguliers says, that a leaden pipe of three fourths of an inch in thickness is strong enough for a height of 140 feet and diameter of seven inches. From this we may calculate all others. Belidor says, that a leaden pipe twelve inches diameter and sixty feet deep should be half an inch thick. But these things will be more properly computed by means of the list given in the article Strength of Materials.

The application which we are most anxious to make of the knowledge of the pressure of moving waters, is the derivation from a main conduit by lateral branches. This occurs very frequently in the distribution of waters among the inhabitants of towns; and it is so imperfectly understood by the greater part of those who take the name of engineers, that individuals have no security that they shall get even one half of the water they bargain and pay for; yet this may be as accurately ascertained as any other problem in hydraulics by means of our general theorem. The case therefore merits our particular attention.

It appears to be already determined, when we have ascertained the pressures by which the water is impelled into these lateral pipes, especially after we have said that the experiments of Bossut on the actual discharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be considered. We have seen that there is a vast difference between the discharge made through a hole, or even through a short pipe, and the discharge from the far end of a pipe derived from a main conduit. And even when this has been ascertained by our new theory, the discharge thus modified will be found considerably different from the real state of things: for when water is flowing along a main with a known velocity, and therefore exerting a known pressure on the circle which we propose for the entry of a branch, if we insert a branch there, water will go along it; but this will generally make a considerable change in the motion along the main, and therefore in the pressure which is to expel the water. It also makes a considerable change in the whole quantity which passes along the anterior part of the main, and a still greater change on what moves along that part of it which lies beyond the branch: it therefore affects the quantity necessary for the whole supply, the force that is required for propelling it, and the quantity delivered by other branches. This part therefore of the management of water in conduits is of considerable importance and intricacy. We can propose in this place nothing more than a solution of such leading questions as involve the chief circumstances, recommending to our readers the perusal of original works on this subject. M. Bossut's experiments are fully competent to the establishment of the fundamental principle. The hole through which the lateral discharges were made was but a few feet from the reservoir. The pipe was successively lengthened, by which the resistances were increased, and the velocity diminished: but this did not affect the lateral discharges, except by affecting the pressures; and the discharges from the end of the main were supposed to be the same as when the lateral pipe was not inserted. Although this was not strictly true, the difference was insensible, because the lateral pipe had but about the eighteenth part of the area of the main.

Suppose that the discharge from the reservoir remains the same after the derivation of this branch, then the motion of the water all the way to the insertion of the branch is the same as before; but beyond this the discharge is diminished by all that is discharged by the branch, with the head x equivalent to the pressure on the side. The discharge by the lower end of the main being diminished, the velocity and resistance in it are also diminished. Therefore the difference between x and the head employed to overcome the friction in this second case, would be a needless or inefficient part of the whole load at the entry, which is impossible; for every force produces an effect, or it is destroyed by some re-action. The effect of the forcing head of water is to produce the greatest discharge corresponding to the obstructions; and thus the discharge from the reservoir, or the supply to the main, must be augmented by the insertion of the branch, if the forcing head of water remains the same. A greater portion therefore of the forcing head was employed in producing a greater discharge at the entry of the main, and the remainder, less than x, produced the pressure on the sides. This head was the one competent to the obstructions resulting from the velocity beyond the insertion of the branch; and this velocity, diminished by the discharge already made, was less than that at the entry, and even than that of the main without a branch. This will appear more distinctly by putting the case into the form of an equation. Therefore let $H - x$ be the height due to the velocity at the entry, of which the effect obtains only horizontally. The head x is the only one which acts on the sides of the tube, tending to produce the discharge by the branch, at the same time that it must overcome the obstructions beyond the branch. If the orifice did not exist, and if the force producing the velocity on a short tube be represented by 2 G, and the section of the main be A, the supply at the entry of the main would be $A\sqrt{2G}\sqrt{H-x}$; and if the orifice had no influence on the value of x, the discharge by the orifice would be $D\sqrt{\frac{x}{H}}$, D being its discharge by means of the head H, when the end of the main is shut; for the discharges are in the subduplicate ratio of the heads of water by which they are expelled; and therefore $\sqrt{H} : \sqrt{x} = D : D\sqrt{\frac{x}{H}} = \delta$. But we have seen that x must diminish; and we know that the obstructions are nearly as the square roots of the velocities, when these do not differ much among themselves. Therefore, calling y the pressure or head which balances the resistances of the main without a branch, while x is the head necessary for the main with a branch, we may institute this proportion, $y : H - y = x : \frac{x(H-y)}{y}$; and this fourth term will express the head producing the velocity in the main beyond the branch (as $H - y$ would have done in a main without a branch). This velocity beyond the branch will be $\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$, and the discharge at the end will be $A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}}$. If to this we add the discharge of the branch, the sum will be the whole discharge, and therefore the whole supply. Therefore we have the following equation, $A\sqrt{2G}\sqrt{H-y} = A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}} + D\sqrt{\frac{x}{H}}$. From this we deduce

$$\text{the value of } x = \frac{2\,GHA^2}{\left(A\sqrt{2G}\sqrt{\frac{H-y}{y}} + \frac{D}{\sqrt{H}}\right)^2 + 2GA^2}.$$

This value of x being substituted in the equation of the discharge δ of the branch, which was $= D\sqrt{\frac{x}{H}}$, will give the discharges required, and they will differ so much the more from the discharges calculated according to the simple theory, as the velocity in the main is greater. By the simple theory, we mean the supposition that the lateral discharges are such as would be produced by the head $H-h$, where H is the height of the reservoir, and h the head due to the actual velocity in the main.

And thus it appears that the proportion of the discharge by a lateral pipe from a main that is shut at the far end, and the discharge from a main that is open, depends not only on the pressures, but also on the size of the lateral pipe, and its distance from the reservoir. When it is large, it greatly alters the train of the main, under the same head, by altering the discharge at its extremity, and the velocity in it beyond the branch; and if it be near the reservoir, it greatly alters the train, because the diminished velocity takes place through a greater extent, and there is a greater diminution of the resistances.

When the branch is taken off at a considerable distance from the reservoir, the problem becomes more complicated, and the head x is resolved into two parts, one of which balances the resistance in the first part of the main, and the other balances the resistances beyond the lateral pipe, with a velocity diminished by the discharge from the branch. A branch at the end of the main produces very little change in the train of the pipe.

When the lateral discharge is great, the train may be so altered, that the remaining part of the main will not run full, and then the branch will not yield the same quantity. The velocity in a very long horizontal tube may be so small (by a small head of water and great obstructions in a very long tube) that it will just run full. An orifice made in its upper side will yield nothing, and yet a small tube inserted into it will carry a column almost as high as the reservoir; so that we cannot judge in all cases of the pressures by the discharges, and *vice versa*.

If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper side near the reservoir. This will yield some water, and the velocity will diminish in the tube till it is in train. If we should now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumstances which affect these lateral discharges. The discharges are afterwards modified by the conduits in which they are conveyed to their places of destination. These, for the sake of economy, being generally of small dimensions, the velocity is much diminished. But, at the same time, it approaches nearer to that which the same conduit would bring directly from the reservoir, because its small velocity will produce a less change in the train of the main conduit.

We should now treat of jets of water, which still make an ornament in the magnificent pleasure-grounds of the wealthy. Some of these are indeed grand objects, such as the two at Peterhoff in Russia, which spout about sixty feet high a column of nine inches diameter, that falls again, and shakes the ground with its blow. Even a spout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly enlivens a pleasure-ground, especially when the changes of a gentle breeze bend the jet to one side. But we have no room left for treating this subject, which is of some nicety; and must conclude this article with a very short account of the management of water as an active power for impelling machinery.

CLASS II.

Of Machinery driven by Water.

This is a very comprehensive article, including almost every possible species of mill. It is no less important, and it is therefore matter of regret that we cannot enter into the detail which it deserves. The mere description of the immense variety of mills which are in general use would fill volumes, and a scientific description of their principles and maxims of construction would almost form a complete body of mechanical science. But this is far beyond the limits of a work like ours. Many of these machines have been already described under their proper names, or under the articles which give an account of their manufactures; and for others we must refer our readers to the original works, where they are described in minute detail. The great academical collection *Des Arts et Metiers*, published in Paris in many folio volumes, contains a description of the peculiar machinery of many mills; and the volumes of the *Encyclopédie Méthodique*, which particularly relate to the mechanical arts, contain many more. All that we can do in this place is, to consider the chief circumstances that are common to all water-mills, and from which all must derive their efficacy. These circumstances are to be found in the manner of employing water as an acting power, and most of them are comprehended in the construction of water-wheels. When we have explained the principles and the maxims of construction of a water-wheel, every reader conversant in mechanics knows that the axis of this wheel may be employed to transmit the force impressed on it to any species of machinery. Therefore nothing subsequent to this can with propriety be considered as *water-works*.

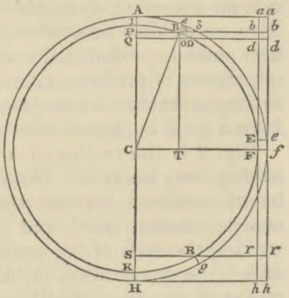
Water-wheels are of two kinds, distinguished by the manner in which water is made an impelling power, viz. by its weight, or by its impulse. This requires a very different form and manner of adaptation; and this forms an ostensible distinction, sufficiently obvious to give a name to each class. When water is made to act by its weight, it is delivered from the spout as high on the wheel as possible, that it may continue long to press it down; but when it is made to strike the wheel, it is delivered as low as possible, that it may have previously acquired a great velocity. And thus the wheels are said to be OVERSHOT or UNDERSHOT.

Of Overshot Wheels.

This is nothing but a frame of open buckets, so disposed round the rim of a wheel as to receive the water delivered from a spout; so that one side of the wheel is loaded with water, while the other is empty. The consequence must be, that the loaded side must descend. By this motion the water runs out of the lower buckets, while the empty buckets of the rising side of the wheel come under the spout in their turn, and are filled with water.

If it were possible to construct the buckets in such a manner as to remain completely filled with water till they come to the very bottom of the wheel, the pressure with which the water urges the wheel round its axis would be the same as if the extremity of the horizontal radius were continually loaded with a quantity of water sufficient to fill a square pipe whose section is equal to that of the bucket, and whose length is the diameter of the wheel. For let the buckets BD and EF, fig. 5, be compared together, the arches DB and EF are equal. The mechanical energy of the water contained in the bucket BD, or the pressure with which its weight urges the wheel, is the same as if all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb-line BT. This is plain from the most elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as CT to CF or CB. Draw the horizontal lines PB $b\,b$, QD $d\,d$. It is plain, that if BD is taken very small, so that it may be considered as a straight line, BD : BO = CB : BP, and EF : $b\,d$ = CF : CT, and EF × CT = $b\,d$ × CF. Therefore, if the prism of water whose vertical section is $b\,b\,d\,d$, were hung on at F, its force to urge the

Fig. 5.



wheel round would be the same as that of the water lying in the bucket BD. The same may be said of every bucket; and the effective pressure of the whole ring of water A *f* HKFI, in its natural situation, is the same with the pillar of water *a h h a* hung on at F. And the effect of any portion BF of this ring is the same with that of the corresponding portion *b* F *f b* of the vertical pillar. We do not take into account the small difference which arises from the depth Bβ or F *f*, because we may suppose the circle described through the centres of gravity of the buckets. And in the further prosecution of this subject, we shall take similar liberties, with the view of simplifying the subject, and saving time to the reader.

But such a state of the wheel is impossible. The bucket at the very top of the wheel may be completely filled with water; but when it comes into the oblique position BD, a part of the water must run over the outer edge δ, and the bucket will only retain the quantity ZBD δ; and if the buckets are formed by partitions directed to the axis of the wheel, the whole water must be run out by the time that they descend to the level of the axis. To prevent this, many contrivances have been adopted. The wheel has been surrounded with a hoop or sweep, consisting of a circular board, which comes almost into contact with the rim of the wheel, and terminates at H, where the water is allowed to run off. But unless the work is executed with uncommon accuracy, the wheel made exactly round, and the sweep exactly fitting it, a great quantity of water escapes between them; and there is a very sensible obstruction to the motion of such a wheel, from something like friction between the water and the sweep. Frost also effectually stops the motion of such a wheel. Sweeps have therefore been generally laid aside, although there are situations where they might be used with good effect.

Mill-wrights have turned their whole attention to the giving a form to the buckets which shall enable them to retain the water along a great portion of the circumference of the wheel. It would be endless to describe all these contrivances; and we shall therefore content ourselves with one or two of the most approved. The intelligent reader will readily see that many of the circumstances which concur in producing the ultimate effect (such as the facility with which the water is received into the buckets, the place which it is to occupy during the progress of the bucket from the top to the bottom of the wheel, the readiness with which they are evacuated, or the chance that the water has of being dragged beyond the bottom of the wheel by its adhesion, &c. &c.) are such as do not admit of precise calculation on reasoning about their merits; and that this or that form can seldom be evidently demonstrated to be the very best possible. But, at the same time, he will see the general reasons of preference, and his attention will be directed to circumstances which must be attended to in order to have a good bucketed wheel.

Fig. 6.

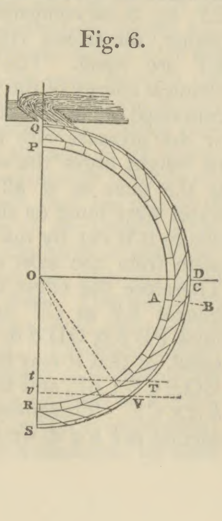


Fig. 6 is the outline of a wheel having forty buckets. The ring of board contained between the concentric circles QDS and PAR, making the ends of the buckets, is called the SHROUDING, in the language of the art, and QP is called the *depth of shrouding*. The inner circle PAR is called the SOLE of the wheel, and usually consists of boards nailed to strong wooden rings of compass-timber of considerable scantling, firmly united with the ARMS or radii. The partitions which determine the form of the buckets consist of three different planes or boards AB, BC, CD, which are variously named by different artists. We have heard them named the START or SHOULDER, the ARM, and the WREST (probably for wrist, on account of a resemblance of the whole line to the human arm); B is also called the ELBOW. Fig. 7 represents a small portion of the same bucketing on a larger scale, that the proportions of the parts may be more distinctly seen. AG, the sole of one bucket, is made about $\frac{1}{5}$th more than the depth GH of the shrouding. The start AB is $\frac{1}{2}$ of AI. The plane BC is so inclined to AB that it would pass through H; but it is made to terminate in C, in such a manner that FC is $\frac{5}{6}$ths of GH or AI. Then CD is so placed that HD is about $\frac{1}{5}$th of IH.

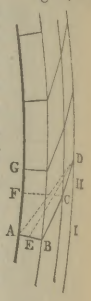
Fig. 7.



By this construction, it follows that the area FABC is very nearly equal to DABC; so that the water which will fill the space FABC will all be contained in the bucket when it shall come into such a position that AD is a horizontal line; and the line AB will then make an angle of nearly 35° with the vertical, or the bucket will be 35° from the perpendicular. If the bucket descend so much lower that one half of the water runs out, the line AB will make an angle of 25°, or 24° nearly, with the vertical. Therefore the wheel, filled to the degree now mentioned, will *begin* to lose water at about $\frac{1}{8}$th of the diameter from the bottom, and *half of the water will be discharged* from the lowest bucket, about $\frac{1}{24}$th of the diameter farther down. These situations of the discharging bucket are marked at T and V in fig. 6. Had a greater proportion of the buckets been filled with water when they were under the spout, the discharge would have begun at a greater height from the bottom, and we should lose a greater portion of the whole fall of water. The loss by the present construction is less than $\frac{1}{10}$th (supposing the water to be delivered into the wheel at the very top), and may be estimated at about $\frac{1}{12}$th; for the loss is the versed sine of the angle which the radius of the bucket makes with the vertical. The versed sine of 35° is nearly $\frac{1}{5}$th of the radius (being 0·18085), or $\frac{1}{10}$th of the diameter. It is evident that if only $\frac{1}{2}$ of this water were supplied to each bucket as it passes the spout, it would have been retained for 10° more of a revolution, and the loss of fall would have been only about $\frac{1}{18}$th.

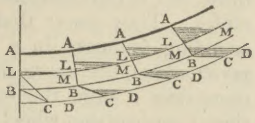
These observations serve to show, in general, that an advantage is gained by having the buckets so capacious that the quantity of water which each can receive as it passes the spout may not nearly fill it. This may be accomplished by making them of a sufficient length, that is, by making the wheel sufficiently broad between the two shroudings. Economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will soon compensate for the additional expense.

The third plane CD is not very frequent, and mill-wrights generally content themselves with continuing the board all the way from the elbow B to the outer edge of the wheel at H; and AB is generally no more than one third of the depth AI. But CD is a very evident improvement, causing the wheel to retain a very sensible addition to the water. Some indeed make this addition more considerable, by bringing BC more outward, so as to meet the rim of the wheel at H, for instance, and making HD coincide with the rim. But this makes the entry of the water somewhat more difficult during the very short time that the opening of the bucket passes the spout. To facilitate this as much as possible, the water should get a direction from the spout, such as will send it into the buckets in the most perfect manner. This may be obtained by delivering water through an aperture that is divided by thin plates of board or metal, placed in the proper position, as we have represented in fig. 6. The form of bucket last mentioned, having the wrest concentric with the rim, is unfavourable to the ready admission of the water; whereas an oblique wrest conducts the water which has missed one bucket into the next below.

he mechanical consideration of this subject also shows us that a deep shrouding, in order to make a capacious bucket, is not a good method: it does not make the buckets retain their water any longer, and it diminishes the effective fall of water; for the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus shortens the fictitious pillar of water, which we showed to be the measure of the effective or useful pressure on the wheel: and this concurs with our former reasons for recommending as great a breadth of the wheel, and length of buckets, as economical considerations will permit.

bucket-wheel was some time ago executed by Mr Robert Burns, at the cotton-mills of Houston, of a construction entirely new, but founded on a good principle, which is susceptible of great extension. It is represented in fig. 8. The bucket consists of a start AB, an arm BC, and a wrest CD, concentric with the rim. But the bucket is also divided by a partition LM, concentric with the sole and rim, and so placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any further reasoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled one third, they retain the whole water at 18° from the bottom, and they retain one half at 11°. They do not admit the water quite so freely as buckets of the common construction; but by means of the contrivance mentioned a little ago for the spout (also the invention of Mr Burns, and furnished with a rack-work, which raised or depressed it as the supply of water varied, so as at all times to employ the whole fall of the water), it is found that a slow moving wheel allows one half of the water to get into the inner buckets, especially if the partition do not altogether reach the radius drawn through the lip D of the outer bucket.

Fig. 8.



his is a very great improvement of the bucket-wheel; and when the wheel is made of a liberal breadth, so that the water may be very shallow in the buckets, it seems to carry the performance as far as it can go. Mr Burns made the first trial on a wheel of twenty-four feet diameter; and its performance is manifestly superior to that of the wheel which it replaced, and which was a very good one. It has also another valuable property: when the supply of water is very scanty, a proper adjustment of the apparatus in the spout will direct almost the whole of the water into the outer buckets, which, by placing it at a greater distance from the axis, makes a very sensible addition to its mechanical energy.

e said that this principle is susceptible of considerable extension; and it is evident that two partitions will increase the effect, and that it will increase with the number of partitions; so that when the practice now begun, of making water-wheels of iron, shall become general, and therefore very thin partitions are used, their number may be greatly increased without any inconvenience, and it is obvious that this series of partitions must greatly contribute to the stiffness and general firmness of the whole wheel.

here frequently occurs a difficulty in the making of bucket-wheels, when the half-taught mill-wright attempts to retain the water a long time in the buckets. The water gets into them with a difficulty which he cannot account for, and spills all about, even when the buckets are not moving away from the spout. This arises from the air, which must find its way out to admit the water, but is obstructed by the entering water, and occasions a great spluttering at the entry. This may be entirely prevented by making the spout considerably narrower than the wheel, which will leave room at the two ends of the buckets for the escape of the air. This obstruction is vastly greater than one would imagine, for the water drags along with it a great quantity of air, as is evident in the *water-blast* described by many authors.

There is another and very serious obstruction to the motion of an overshot or bucketed wheel. When it moves in back-water, it is not only resisted by the water when it moves more slowly than the wheel, which is very frequently the case, but it lifts a great deal in the rising buckets. In some particular states of back-water, the descending bucket fills itself completely with water, and in other cases it contains a very considerable quantity, and air of common density; while in some rarer cases it contains less water, with air in a condensed state. In the first case the rising bucket must come up filled with water, which it cannot drop till its mouth get out of the water. In the second case, part of the water goes out before this, but the air rarefies, and therefore there is still some water dragged or lifted up by the wheel, by suction, as it is usually called. In the last case there is no such back-load on the rising side of the wheel, but (which is as detrimental to its performance) the descending side is employed in condensing air; and although this air aids the ascent of the rising side, it does not aid it so much as it impedes the descending side, being (by the form of the bucket) nearer to the vertical line drawn through the axis.

All this may be completely prevented by a few holes made in the start of each bucket. Air being at least 800 times rarer than water, will escape through a hole almost thirty times faster with the same pressure. Very moderate holes will therefore suffice for this purpose; and the small quantity of water which these holes discharge during the descent of the buckets, produces a loss which is altogether insignificant. The water which runs out of one runs into another, so that there is only the loss of one bucket. We have seen a wheel of only fourteen feet diameter working in nearly three feet of back-water. It laboured prodigiously, and brought up a great load of water, which fell from it in abrupt dashes, rendering the motion very hobbling. When three holes of an inch diameter were made in each bucket (twelve feet long), the wheel laboured no more, there was no more plunging of water from its rising side, and its power on the machinery was increased more than one fourth.

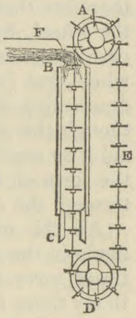
These practical observations may contain information that is new even to several experienced mill-wrights. To persons less informed they cannot fail of being useful. We now proceed to consider the action of water thus lying in the buckets of a wheel, and to ascertain its energy as it may be modified by different circumstances of fall, velocity, &c.

With respect to variations in the fall, there can be little room for discussion. Since the active pressure is measured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is spilled by the wheel, it is evident that it must be proportional to this pillar, and therefore we must deliver it as high and retain it as long as possible.

This maxim obliges us, in the first place, to use a wheel whose diameter is equal to the whole fall. We shall not gain any thing by employing a larger wheel; for although we should gain by using only that part of the circumference where the weight will act more perpendicularly to the radius, we shall lose more by the necessity of discharging the water at a greater height from the bottom: for we must suppose the buckets of both the wheels equally well constructed; in which case, the heights above the bottom where they will discharge the water, will increase in the proportion of the diameter of the wheel. Now, that we shall lose more by this than we gain by the more direct application of the weight, is plain, without any further reasoning, by taking the extreme case, and supposing our wheel enlarged to such a size that the useless part below is equal to the whole fall. In this case the water will be spilled from the buckets as soon as it is delivered into them. All intermediate cases therefore partake of the imperfection of this.

When the fall is exceedingly great, a wheel of an equal diameter becomes enormously large and expensive, and is of itself an unmanageable load. We have however seen wheels of fifty-eight feet diameter, which worked extremely well; but they are of very difficult construction, and extremely apt to warp and go out of shape by their weight. In cases like this, where we are unwilling to lose any part of the force of a small stream, the best form of a bucket-wheel is an inverted chain-pump. Instead of employing a chain-pump of the best construction, ABCDEA (fig. 9), to raise water through the upright pipe CB, by means of a force applied to the upper wheel A, let the water be delivered from a spout F, into the upper part of a pipe BC, and it will press down the plugs in the lower and narrower bored part of it with the full weight of the column, and escape at the dead level of C. This weight will urge round the wheel A without any defalcation; and this is the most powerful manner in which any fall of water whatever can be applied, and it exceeds the most perfect overshot wheel. But though it excels all chains of buckets in economy and in effect, it has all the other imperfections of this kind of machinery. Though the chain of plugs be of great strength, it has so much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A, on the loaded side, and all comes down with a great crash. There is also a loss of power by the immersion of so many plugs and chains in the water; for there can be no doubt but that if the plugs were large enough and light enough, they would buoy and even draw up the plug in the narrow part at C. They must therefore diminish, in all other cases, the force with which this plug is pressed down.

Fig. 9.



The velocity of an overshot wheel is a matter of very great nicety; and authors, both speculative and practical, have entertained different, nay opposite, opinions on the subject. M. Belidor, whom the engineers of Europe have long been accustomed to regard as sacred authority, maintains that there is a certain velocity related to that obtainable by the whole fall, which will procure to an overshot wheel the greatest performance. Desaguliers, Smeaton, Lambert, De Parcieux, and others, maintain that there is no such relation, and that the performance of an overshot wheel will be the greater, as it moves more slowly by an increase of its load of work. Belidor maintains that the active power of water lying in a bucket-wheel of any diameter is equal to that of the impulse of the same water on the floats of an undershot wheel when the water issues from a sluice in the bottom of the dam. The other writers whom we have named assert that the energy of an undershot wheel is but one half of that of an overshot, actuated by the same quantity of water falling from the same height.

To a manufacturing country like ours, that derives astonishing superiority, by which it more than compensates for the impediments of heavy taxes and luxurious living, chiefly from its machinery, in which it leaves all Europe far behind, the decision of this question, in such a manner as shall leave no doubt or misconception in the mind even of an unlettered artist, must be considered as a material service, and we think that this is easily attainable.

When any machine moves uniformly, the accelerating force or pressure actually exerted on the impelled point of the machine is in equilibrio with all the resistances which are exerted at the working point, with those arising from friction, and those that are excited in different parts of the machine by their mutual actions. This is an incontestable truth, and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Therefore, when an overshot wheel moves uniformly, with *any velocity whatever*, the water is acting with its whole weight, for gravity would accelerate its descent, if not completely balanced by some re-action; and in this balance gravity and the re-acting part of the machine exert equal and opposite pressures, and thus produce the uniform motion of the machine. We are thus particular on this point, because we observe mechanicians of the first name employing a mode of reasoning on the question now before us which is specious, and appears to prove the conclusion which they draw, but is nevertheless contrary to true mechanical principles. They assert that the slower a heavy body is descending (suppose in a scale suspended from an axis *in peritrochea*), the more does it press on the scale, and the more does it urge the machine round; and therefore the slower an overshot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done; but this is not because a pound of water presses more strongly, but because there is more water pressing on the wheel, for the spout supplies at the same rate, and each bucket receives more water as it passes by it.

Let us therefore examine this point by the unquestionable principles of mechanics.

Let the overshot wheel AfH (fig. 5) receive the water from a spout at the very top of the wheel; and in order that the wheel may not be retarded by dragging into motion the water simply laid into the uppermost bucket at A, let it be received at B, with the velocity (directed in a tangent to the wheel) acquired by the head of water AB. This velocity therefore must be equal to that of the rim of the wheel. Let this be v, or let the wheel and the water move over v inches in a second. Let the buckets be of such dimensions, that all the water which each receives as it passes the spout is retained till it comes to the position R, where it is discharged at once. It is plain that, in place of the separate quantities of water lying in each bucket, we may substitute a continued ring of water, equal to their sum, and uniformly distributed in the space $BER\varrho f\beta$. This constitutes a ring of uniform thickness. Let the area of its cross section βB and Ff be called a. We have already demonstrated, that the mechanical energy with which this water on the circumference of the wheel urges it round is the same with what would be exerted by the pillar $brrt$ pressing on Ff, or acting by the lever CF. The weight of this pillar may be expressed by $a \times br$, or $a \times PS$; and if we call the radius CF of the wheel R, the momentum or mechanical energy of this weight will be represented by $a \times PS \times R$.

Now, let us suppose that this wheel is employed to raise a weight W, which is suspended by a rope wound round the axis of the wheel. Let r be the radius of this axle. Then $W \times r$ is the momentum of the work. Let the weight rise with the velocity u when the rim of the wheel turns with the velocity v, that is, let it rise u inches in a second. Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we must have $W \times r = a \times PS \times R$. But it is evident that $R : r = v : u$. Therefore $W \times u = a \times v \times PS$.

Now the performance of the machine is undoubtedly measured by the weight and the height to which it is raised in a second, or by $W \times u$. Therefore the machine is in its be possible state when $a \times v \times$ PS is a maximum. But it plain that $a \times v$ is an invariable quantity, for it is the cuc inches of water which the spout supplies in a second. If he wheel moves fast, little water lies in each bucket, and small. When v is small, a is great, for the opposite reon; but $a \times v$ remains the same. Therefore we must me PS a maximum, that is, we must deliver the water as hi up as possible. But this diminishes AP, and this dishes the velocity of the wheel; and as this has no limit, th proposition is demonstrated, and an overshot wheel des the more work as it moves slowest.

onvincing as this discussion must be to any mechanici, we are anxious to impress the same maxim on the mds of practical men, unaccustomed to mathematical reoning of any kind. We therefore beg indulgence for ang a popular view of the question, which requires no su investigation.

Ve may reason in this way. Suppose a wheel having thy buckets, and that six cubic feet of water are delivern a second on the top of a wheel, and discharged without any loss by the way at a certain height from the botto of the wheel. Let this be the case whatever is the ra of the wheel's motion, the buckets being of a sufficient cacity to hold all the water which falls into them. Let th wheel be employed to raise a weight of any kind, suppo water in a chain of thirty buckets, to the same height ar with the same velocity. Suppose further, that when thload on the rising side of the machine is one half of that orhe wheel, the wheel makes four turns in a minute, or on turn in fifteen seconds. During this time ninety cubic fe of water have flowed into the thirty buckets, and each ha received three cubic feet. Then each of the rising buets contains $1\frac{1}{2}$ feet, and forty-five cubic feet are delived into the upper cistern during one turn of the wheel, ar 180 cubic feet in one minute.

ow, suppose the machine so loaded, by making the rig buckets more capacious, that it makes only two turns in minute, or one turn in thirty seconds. Then each descding bucket must contain six cubic feet of water. If ea bucket of the rising side contained three cubic feet, the mion of the machine would be the same as before. This is point which no mechanician will controvert. When tw pounds are suspended to one end of a string which paes over the pulley, and one pound to the other end, the deent of the two pounds will be the same with that of a fo pound weight which is employed in the same manner toraw up two pounds. Our machine would therefore contie to make four turns in the minute, and would deliver nity cubic feet during each turn, and 360 in a minute. B by supposition, it is making but two turns in a minute: th must proceed from a greater load than three cubic feet of ater in each rising bucket. The machine must therefo be raising *more* than ninety feet of water during one tu of the wheel, and *more* than 180 in the minute.

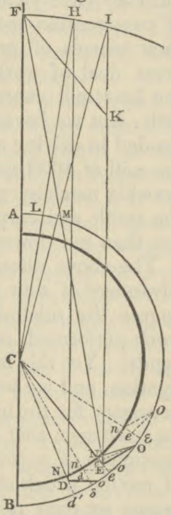
hus it appears, that if the machine be turning twice as sl as before, there is *more than twice the former quantity* inhe rising buckets, and more will be raised in a minute byhe same expenditure of power. In like manner, if the mhine go three times as slow, there must be *more than th times* the former quantity of water in the rising bukets, and more work will be done.

ut we may go further, and assert, that the *more* we reta the machine, by loading it with more work of a simila kind, the greater will be its performance. This does no immediately appear from the present discussion: but les call the first quantity of water in the rising bucket A the water raised by four turns in a minute will be 4 $30 \times A = 120$ A. The quantity in this bucket, when th machine goes twice as slow, has been shown to be grter than 2 A (call it $2A + x$); the water raised by tw turns in a minute will be $2 \times 30 \times (2A + x) = 120A + 60x$. Now, let the machine go four times as slow, making but one turn in a minute, the rising bucket must now contain more than twice $2A + x$, or more than $4A + 2x$; call it $4A + 2x + y$. The work done by one turn in a minute will now be $30 \times (4A + 2x + y) = 120A + 60x + 30y$.

By such an induction of the work, done with any rates of motion we choose, it is evident that the performance of the machine increases with every diminution of its velocity that is produced by the mere addition of a similar load of work, or that it does the more work the slower it goes.

We have supposed the machine to be in its state of permanent uniform motion. If we consider it only in the beginning of its motion, the result is still more in favour of slow motion: for, at the first action of the moving power, the inertia of the machine itself consumes part of it, and it acquires its permanent speed by degrees, during which the resistances arising from the work, friction, &c. increase, till they exactly balance the pressure of the water; and after this the machine accelerates no more. Now the greater the power and the resistance arising from the work are in proportion to the inertia of the machine, the sooner will all arrive at its state of permanent velocity.

Fig. 10.



There is another circumstance which impairs the performance of an overshot wheel moving with a great velocity, viz. the effects of the centrifugal force on the water in the buckets. Our millwrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this cause. The following very simple construction will determine this. Let AOB (fig. 10) be an overshot wheel, of which AB is the upright diameter, and C is the centre. Make CF the length of a pendulum which will make two vibrations during one turn of the wheel. Draw FE to the elbow of any of the buckets. The water in this bucket, instead of having its surface horizontal, as NO, will have it in the direction nO perpendicular to FE very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel, as the radius of a circle is to its circumference; and it is well known that the time of moving along half of AC, by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of describing one half of AC by the centrifugal force, is equal to the time of describing one half of FC by gravity. These spaces, being similarly described in equal times, are proportional to the accelerating forces. Therefore $\frac{1}{2}$ FC : $\frac{1}{2}$ AC, or FC : AC = gravity : centrifugal force. Complete the parallelogram FCEK. A particle at E is urged by its weight in the direction KE with a force which may be expressed by FC or KE; and it is urged by the centrifugal force in the direction CE, with a force = AC or CE. By their combined action it is urged in the direction FE. Therefore, as the surface of standing water is always at right angles to the action of gravity, that is, to the plumb-line, so the surface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the position of the bucket, which just holds all the water which it received as it passed the spout when not affected by the centrifugal force; and let NDO be its position when it would be empty. Let the vertical lines through D and E cut the circle described round C with the radius CF in the points H and I. Draw HC, IC, cutting the circle AOB in L and M. Make the arch *d'* δ equal to AL, and the arch *e'* ε equal to AM: then C δ and C ε will be the positions of the bucket on the revolving wheel, corresponding to CD*o* and CEO on the wheel at rest. Water will begin to run out at ε, and it will be all gone at δ. The demonstration is evident.

The force which now urges the wheel is still the weight *really* in the buckets; for though the water be urged in the direction with the force FE, one of its constituents, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been constructed or attended to with that accuracy and scientific skill which are necessary for deducing confident conclusions from any experiments that can be made with them; and it is therefore no matter of wonder that the opinions of mill-wrights have been so different on this subject. There is a natural wish to see a machine moving briskly; it has the appearance of activity; but a very slow motion always looks as if the machine were overloaded. For this reason mill-wrights have always yielded slowly, and with some reluctance, to the repeated advices of the mathematicians: but they have yielded, and we see them adopting maxims of construction more agreeable to sound theory, making their wheels of great breadth, and loading them with a great deal of work. Euler says that the performance of the best mill cannot exceed that of the worst above one fifth; but we have seen a stream of water completely expended in driving a small flax-mill, which now drives a cotton-mill of 4000 spindles, with all its carding, roving, and drawing machinery, besides the lathes and other engines of the smith and carpenter's workshops, exerting a force not less than ten times what sufficed for the flax-mill.

The above discussion only demonstrates in general the advantage of slow motion, but does not point out in any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a subject fit for a mathematical investigation, and we would prosecute it in this place if it were necessary for the improvement of practical mechanics. But we have seen that there is not, in the nature of things, a maximum of performance attached to any particular rate of motion which should therefore be preferred. For this reason we omit this discussion of mere speculative curiosity. It is very intricate; for we must now express the pressure on the wheel by a *constant* pillar of water incumbent on the extremity of the horizontal arm, as we did before when we supposed the buckets completely filled; nor by a smaller *constant* pillar, corresponding to a smaller but equal quantity lying in every bucket. Each different velocity puts a different quantity of water into the bucket as it passes the spout, and this occasions a difference in the place where the discharge is begun and completed. This circumstance is some obstacle to the advantages of very slow motions, because it brings on the discharge sooner. All this may indeed be expressed by a simple equation of easy management; but the whole process of the mechanical discussion is both intricate and tedious, and the results are so much diversified by the forms of the buckets, that they do not afford any rule of sufficient generality to reward our trouble. The curious reader may see a very full investigation of this subject in two dissertations by Elvius in the Swedish Transactions, and in the *Hydrodynamique* of Professor Kästner of Göttingen, who has abridged these dissertations of Elvius, and considerably improved the whole investigation, and has added some comparisons of his deductions with the actual performance of some great works. These comparisons however are not very satisfactory. There is also a very valuable paper on this subject by Lambert, in the Memoirs of the Academy of Berlin for the year 1775. From these dissertations, and from the *Hydrodynamique* of the Abbé Bossut, the reader will acquire all that theory can teach of the relation between the pressures of the power and work on the machine, and the rates of its motion. The practical reader may rest with confidence on the simple demonstration which we have given, that the performance is improved by diminishing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminish its speed, unless other physical circumstances throw obstacles in the way; but there are such obstacles. In all machines there are little inequalities of action that are unavoidable. In the action of a wheel and pinion, though made with the utmost judgment and care, there are such inequalities. These increase by the changes of form occasioned by the wearing of the machine: much greater irregularities arise from the subsultory motions of cranks, stampers, and other parts which move unequally or reciprocally. A machine may be so loaded as just to be in equilibrio with its work, in the favourable position of its parts. When this changes into one less favourable, the machine may stop; if not, it at least staggers, hobbles, or works unequally. The rubbing parts bear long on each other, with enormous pressures, and cut deep, and increase friction. Such slow motions must therefore be avoided. A little more velocity enables the machine to get over those increased resistances by its inertia, or the great quantity of motion inherent in it. Great machines possess this advantage in a superior degree, and will therefore work steadily with a smaller velocity. These circumstances are hardly susceptible of mathematical discussion, and our best reliance is on well-directed experience.

For this purpose, the reader will do well to peruse with care the excellent paper by Mr Smeaton in the Philosophical Transactions for 1759. This dissertation contains a numerous list of experiments, most judiciously contrived by him, and executed with the accuracy and attention to the most important circumstances which is to be observed in all that gentleman's performances.

It is true, these experiments were made with small models; and we must not, without great caution, transfer the results of such experiments to large works. But we may safely transfer the laws of variation which result from a variation of circumstances, although we must not adopt the absolute quantities of the variations themselves. Mr Smeaton was fully aware of the limitations to which conclusions drawn from experiments on models are subject, and has made the applications with his usual sagacity.

His general inference is, that, in smaller works, the rim of the overshot wheel should not have a greater velocity than three feet in a second; but that larger mills may be allowed a greater velocity than this. When every thing is executed in the best manner, he says that the work performed will amount to fully two thirds of the power expended; that is, that three cubic feet of water descending from any height will raise two to the same height.

It is not very easy to compare these deductions with observations on large works; because there are few cases where we have good measures of the resistances opposed by the work performed by the machine. Mills employed for pumping water afford the best opportunities. But the inertia of their working gear diminishes their useful performance very sensibly, because their great beams, pump-rods, &c. have a reciprocating motion, which must be destroyed and produced anew in every stroke. We have examined some machines of this kind which are esteemed good ones, and we find few of them whose performance exceeds one half of the power expended.

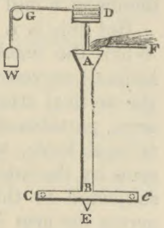
By comparing other mills with these, we obtain the best information of their resistances. The comparison with mills worked by Watt and Boulton's steam-engines, is perhaps a better measure of the resistances opposed by different kinds of work, because their power is very distinctly known. We have been informed by one of the most eminent engineers, that a ton and a half of water per minute falling one foot will grind and dress one bushel of wheat per hour. This is equivalent to nine tons falling ten feet.

If an overshot wheel opposed no resistance, and only one bucket were filled, the wheel would acquire the velocity due to a fall through the whole height. But when it is in this state of accelerated motion, if another bucket of water is delivered into it, its motion must be checked at the first, by the necessity of dragging forward this water. If the buckets fill in succession as they pass the spout, the velocity acquired by an unresisting wheel is but half of that which one bucket would give. In all cases, therefore, the velocity is diminished by the inertia of the entering water when it is simply laid into the upper buckets. The performance will therefore be improved by delivering the water on the wheel with that velocity with which the wheel is really moving. And as we cannot give the direction of a tangent to the wheel, the velocity with which it is delivered on the wheel must be so much greater than the intended velocity of the rim, that it shall be precisely equal to it when it is estimated in the direction of the tangent. Three or four inches of fall are sufficient for this purpose; and it should never be neglected, for it has a very sensible influence on the performance. But it is highly improper to give it more than this, with the view of impelling the wheel by its stroke; for even although it were proper to employ part of the fall in this way (which we shall presently see to be very improper), we cannot procure this impulse; because the water falls among other water, or it strikes the boards of the wheel with such obliquity that it cannot produce any such effect.

It is a much debated question among mill-wrights, whether the diameter of the wheel should be such that the water will be delivered at the top of the wheel; or larger, so that the water is received at some distance from the top, where it will act more perpendicularly to the arm. We apprehend that the observations formerly made will decide in favour of the first practice. The space below, where the water is discharged from the wheel, being proportional to the diameter of the wheel, there is an undoubted loss of fall attending a large wheel; and this is not compensated by delivering the water at a greater distance from the perpendicular. We should therefore recommend the use of the whole descending side, and make the diameter of the wheel no greater than the fall, till it is so much reduced that the centrifugal force begins to produce a sensible effect. Since the rim can hardly have a smaller velocity than three feet per second, it is evident that a small wheel must revolve more rapidly. This made it proper to insert the determination that we have given of the loss of power produced by the centrifugal force. But even with this view, we should employ much smaller wheels than are generally done on small falls. Indeed the loss of water at the bottom may be diminished, by nicely fitting the arch which surrounds the wheel, so as not to allow the water to escape by the sides or bottom. While this improvement remains in good order, and the wheel entire, it produces a very sensible effect; but the passage widens continually by the wearing of the wheel. A piece of wood or stone falling in about the wheel tears off part of the shrouding or buckets, and frosty weather frequently binds all fast. It therefore seldom answers expectations. We have nothing to add on this case to what we have already extracted from Mr Smeaton's Dissertation on the subject of Breast or Half Overshot Wheels.

There is another form of wheel by which water is made to act on a machine by its weight, which merits consideration. It is known in this country by the name of *Barker's mill*, and has been described by Desaguliers, vol. ii. p. 460. It consists of an upright pipe or trunk AB (fig. 11), communicating with two horizontal branches BC, B*c*, which have a hole C*c* near their ends, opening in opposite directions, at right angles to their lengths. Suppose water to be poured in at the top from the spout F, it will run out by the holes C and *c* with the velocity corresponding to the depth of these holes under the surface. The consequence of this must be, that the arms will be pressed backwards; for there is no solid surface at the hole C, on which the lateral pressure of the water can be exerted, while it acts with its full force on the opposite side of the arm. This unbalanced pressure is equal to the weight of a column having the orifice for its base, and twice the depth under the surface of the water in the trunk for its height. This measure of the height may seem odd, because if the orifice were shut, the pressure on it is the weight of a column reaching from the surface. But when it is open, the water issues with nearly the velocity acquired by falling from the surface, and the quantity of motion produced is that of a column of twice this length, moving with this velocity. This is actually produced by the pressure of the fluid, and must therefore be accompanied by an equal re-action.

Fig. 11.

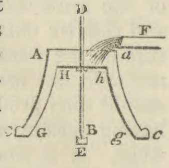


Now suppose this apparatus set on the pivot E, and to have a spindle AD above the trunk, furnished with a cylindrical bobbin D, having a rope wound round it, and passing over a pulley G. A weight W may be suspended there, which may balance this backward pressure. If the weight be too small for this purpose, the retrograde motion of the arms will wind up the cord, and raise the weight; and thus we obtain an acting machine, employing the pressure of the water, and applicable to any purpose. A runner millstone may be put on the top of the spindle; and we should then produce a flour-mill of the greatest simplicity, having neither wheel nor pinion, and subject to hardly any wear. It is somewhat surprising, that although this was invented at the beginning of last century, and appears to have such advantage in point of simplicity, it has not come into use. So little has Dr Desaguliers's account been attended to (although it is mentioned by him as an excellent machine, and as highly instructive to the hydraulist), that the same invention was again brought forward by a German professor (Segner) as his own, and has been honoured by a series of elaborate disquisitions concerning its theory and performance by Euler and by John Bernoulli. Euler's Dissertations are to be found in the Memoirs of the Academy of Berlin, 1751, &c. and in the *Nov. Comment. Petropol.* tom. vi. Bernoulli's are at the end of his Hydraulics. Both these authors agree in saying that this machine excels all other methods of employing the force of water. Simple as it appears, its true theory, and the best form of construction, are most abstruse and delicate subjects; and it is not easy to give such an account of its principles as will be understood by an ordinary reader.

We see in general that the machine must press backwards; and little investigation suffices for understanding the intensity of this pressure when the machine is at rest. But when it is allowed to run backwards, withdrawing itself from the pressure, the intensity of it is diminished; and if no other circumstances intervened, it might not be difficult to say what particular pressure corresponded to any rate of motion. Accordingly, Desaguliers, presuming on the simplicity of the machine, affirms the pressure to be the weight of a column which would produce a velocity of efflux equal to the difference of the velocity of the fluid and of the machine; and hence he deduces that its performance will be the greatest possible when its retrograde velocity is one third of the velocity acquired by falling from the surface, in which case it will raise $\frac{8}{27}$ths of the water expended to the same height, which is double of the performance of a mill acted on by the impulse of water.

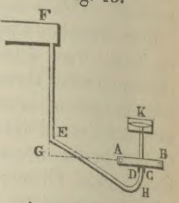
But this is a very imperfect account of the operation. When the machine (constructed exactly as we have described) moves round, the water which issues descends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This excites a centrifugal force, which is exerted against the ends of the arms by the intervention of the fluid. The whole fluid is subjected to this pressure (increasing for every section across the arm in the proportion of its distance from the axis), and every particle is pressed with the accumulated centrifugal forces of all the sections that are nearer to the axis. Every section therefore sustains an actual pressure proportional to the square of its distance from the axis. This increases the velocity of efflux, and this increases the velocity of revolution; and this mutual co-operation would seem to terminate in an infinite velocity of both motions. But, on the other hand, this circular motion must be given anew to every particle of water as it enters the horizontal arm. This can be done only by the motion already in the arm, and at its expense. Thus there must be a velocity which cannot be overpassed even by an unloaded machine. But it is also plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very slow, and much of this diminution of circular motion prevented. Accordingly, Euler has recommended a form by which this is done in the most eminent degree. His machine consists of a hollow conoidal ring, of which fig. 12 is a section. The part AH*ha* is a sort of funnel-basin, which receives the water from the spout F, not in the direction pointing towards the axis, but in the direction, and with the precise velocity, of its motion. This prevents any retardation by dragging forward the water. The water then passes down between the outer conoid AC*ca* and the inner conoid HG*gh* along spiral channels formed by partitions soldered to both conoids. The curves of these channels are determined by a theory which aims at the annihilation of all unnecessary and improper motions of the water, but which is too abstruse to find a place here. The water thus conducted arrives at the bottom CG*cg*. On the outer circumference of this bottom is arranged a number of spouts (one for each channel), which are all directed one way in tangents to the circumference.

Fig. 12.



Adopting the common theory of the re-action of fluids, this should be a very powerful machine, and should raise $\frac{8}{27}$ths of the water expended. But if we admit the reaction to be equal to the force of the issuing fluid (and we do not see how this can be refused), the machine must be nearly twice as powerful. We therefore repeat our wonder that it has not been brought into use. But it appears that no trial has been made even of a model; so that we have no experiments to encourage an engineer to repeat the trial. Even the late author Professor Segner has not related any thing of this kind in his *Exercitationes Hydraulicæ*, where he particularly describes the machine. Such remissness has probably proceeded from fixing the attention on Euler's improved construction. It is plain that this must be a most cumbrous mass, even in a small size requiring a prodigious vessel, and carrying an unwieldy load. If we examine the theory which recommends this construction, we find that the advantages, though real and sensible, bear but a small proportion to the whole performance of the simple machine as invented by Dr Barker. It is therefore to be regretted that engineers have not attempted to realize the first project. We beg leave to recommend it, with a further argument taken from an addition made to it by M. Mathon de la Cour, in Rozier's *Journal de Physique*, January and August 1775. This gentleman brings down a large pipe FEH (fig. 13) from a reservoir, bends it upward at H, and introduces it into two horizontal arms DA, DB, which have an upright spindle DK, carrying a millstone in the style of Dr Barker's mill. The ingenious mechanician will have no difficulty of contriving a method of joining these pipes, so as to permit a free circular motion without losing much water. The operation of the machine in this form is evident. The water, pressed by the column FG, flows out at the holes A and B, and the unbalanced pressure on the opposite sides of the arms forces them round. The compendiousness and other advantages of this construction are more striking, allowing us to make use of the greatest fall without any increase of the size of the machine. It undoubtedly enables us to employ a stream of water too scanty to be employed in any other form. The author gives the dimensions of an engine which he had seen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is $1\frac{1}{6}$; FG is 21 feet; the pipe D was fitted into C by grinding, and the internal diameter of D is 2 inches.

Fig. 13.

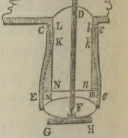


When the machine was performing no work, or was unloaded, and emitted water by one hole only, it made 115 turns in a minute; thus giving a velocity of forty-six feet per second for the hole. This is a curious fact; for the water would issue from this hole at rest with the velocity of $37\frac{1}{6}$. This great velocity (which was much less than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly seventeen times the weight of the water in the orifice.

The empty machine weighed eighty pounds, and its weight was half supported by the upper pressure of the water, so that the friction of the pivots was much diminished. It is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall. His theory by no means embraces all its principles, nor is it well founded.

We think that the free motion round the neck of the feeding pipe, without any loss of water or any considerable friction, may be obtained in the following manner. AB (fig. 14) represents a portion of the revolving horizontal pipe, and CE*ec* part of the feeding pipe. The neck of the first is turned truly cylindrical, so as to turn easily, but without shake, in the collar C*c* of the feeding pipe, and each has a shoulder which may support the other. That the friction of this joint may not be great, and the pipes destroy each other by wearing, the horizontal pipe has an iron spindle EF, fixed exactly in the axis of the joint, and resting with its pivot F in a step of hard steel, fixed to the iron bar GH, which goes across the feeding pipe, and is firmly supported in it. This pipe is made bell-shaped, widening below. A collar or hose of thin leather is fitted to the inside of this pipe, and is represented (in section) by LKM*mkl*. It is kept in its place by means of a metal or wooden ring N*n*, thin at the upper edge, and taper-shaped. This is drawn in above the leather, and stretching it, causes it to apply to the side of the pipe all around. There can be no leakage at this joint, because the water will press the leather to the smooth metal pipe; nor can there be any sensible friction, because the water gets at the edge of the leather, and the whole unbalanced pressure

Fig. 14.



is at the small crevice between the two metal shoulders. The shoulders need not touch, so that the friction must be insensible. We imagine that this method of tightening a turning joint may be used with great advantage in many cases.

We have only further to observe on this engine, that any imperfection by which the passage of the water is diminished or obstructed produces a saving of water, which is in exact proportion to the diminution of effect. The only inaccuracy that is not thus compensated, is when the jets are not at right angles to the arms.

We repeat our wishes, that engineers would endeavour to bring this machine into use, seeing many situations where it may be employed to great advantage. Suppose, for instance, a small supply of water from a great height applied in this manner to a centrifugal pump, or to a hair belt passing over a pulley, and dipping in the water of a deep well. This would be a hydraulic machine exceeding all others in simplicity and durability, though inferior in effect to some other constructions.

Of Undershot Wheels.

All wheels go by this name where the motion of the water is quicker than that of the partitions or boards of the wheel, and it therefore impels them. These are called the *float-boards*, or *floats*, of an undershot wheel. The water, running in a mill-row, with a velocity derived from a head of water or from a declivity of channel, strikes on these floats, and occasions, by its deflections sidewise and upwards, a pressure on the floats sufficient for impelling the wheel.

There are few points of practical mechanics that have been more considered than the action of water on the floats of a wheel; hardly a book of mechanics being silent on the subject. But the generality of them, at least such as are intelligible to persons who are not very much conversant in dynamical and mathematical discussion, have hardly done anything more than copied the earliest deductions from the simple theory of the resistance of fluids. The consequence has been, that our practical knowledge is very imperfect; and it is chiefly from experience that we must still learn the performance of undershot wheels. Unfortunately this stops their improvement; because those who have the only opportunities of making the experiments are not sufficiently acquainted with the principles of hydraulics, and are apt to ascribe differences in their performance to trifling nostrums in their construction, or in the manner of applying the impulse of the water.

We have said so much on the imperfection of our theories of the impulse of fluids in the article RESISTANCE OF FLUIDS, that we need not here repeat the defects of the common explanations of the motions of undershot wheels. The part of the theory of the impulse of fluids which agrees best with observation is, *that the impulse is in the duplicate proportion of the velocity with which the water strikes the float*; that is, if v be the velocity of the stream, and u the velocity of the float, we shall have F, the impulse on the float when held fast, to its impulse f on the float moving with the velocity u, as v^2 to $(v-u)^2$, and $f = \mathrm{F}\times\frac{(v-u)^2}{v^2}$.

This is the pressure acting on the float, and urging the wheel round its axis. The wheel must yield to this motion, if the resistance of the work does not exert a superior pressure on the float in the opposite direction. By yielding, the float withdraws from the impulse, and this is therefore diminished. The wheel accelerates, the resistances increase, and the impulses diminish till they become an exact balance for the resistances. The motion now remains uniform, and the momentum of impulse is equal to that of resistance. The performance of the mill therefore is determined by this; and, whatever be the construction of the mill, its performance is best when the momentum of impulse is greatest. This is had by multiplying the pressure on the float by its velocity. Therefore the momentum will be expressed by $\mathrm{F}\times\frac{(v-u)^2}{v^2}\times u$. But since F and v^2 are constant quantities, the momentum will be proportional to $u\times(v-u)^2$. Let x represent the relative velocity. Then $v-x$ will be $=u$, and the momentum will be proportional to $(v-x)\times x^2$, and will be a maximum when $(v-x)\times x^2$ is a maximum, or when vx^2-x^3 is a maximum. This will be discovered by making its fluxion $=0$; that is,

$$2vxdx-3x^2dx=0$$

and $\quad 2vx-3x^2=0$,

or $\quad 2v-3x=0$

and $\quad 2v=3x$, and $x=\frac{2}{3}v$; and therefore $v-x$, or $u=\frac{1}{3}v$. That is, the velocity of the float must be one third of the velocity of the stream. It only remains to say what is the absolute pressure on the float thus circumstanced. Let the velocity v be supposed to arise from the pressure of a head of water h. The common theory teaches that the impulse on a given surface S at rest is equal to the weight of a column hS; put this in place of F, and $\frac{4}{9}v^2$ in place of $(v-u)^2$ and $\frac{1}{3}v$ for u. This gives us $\mathrm{S}h\times\frac{4}{27}v$ for the momentum. Now the power expended is Shv, or the column Sh moving with the velocity v. Therefore the greatest performance of an undershot wheel is equivalent to raising $\frac{4}{27}$ths of the water that drives it to the same height.

But this is too small an estimation; for the pressure exerted on a plane surface, situated as the float of a mill-wheel, is considerably greater than the weight of the column Sh. This is nearly the pressure on a surface wholly immersed in the fluid. But when a small vein strikes a larger plane, so as to be deflected on all sides in a thin sheet, the impulse is almost double of this. This is in some measure the case in a mill-wheel. When the stream strikes it, it is heaped up along its face, and falls back again, and during this motion it is acting with a hydrostatic pressure on it. When the wheel dips into an open river, this accumulation is less remarkable, because much escapes laterally; but in a mill-course it may be considerable.

We have considered only the action on one float, but several generally act at once. The impulse on most of them must be oblique, and is therefore less than when the same stream impinges perpendicularly; and this diminution of impulse is, by the common theory, in the proportion of the sine of the obliquity. For this reason it is maintained, that the impulse of the whole stream on the lowest float-board, which is perpendicular to the stream, is equal to the sum of the impulses made on all the floats which then dip into the water; or that the impulse on any oblique float is precisely equal to the impulse which that part of the stream would have made on the lowest float-board had it not been interrupted. Therefore it has been recommended to make such a number of float-boards, that when one of them is at the bottom of the wheel, and perpendicular to the stream, the next in succession should be just entering into the water. But since the impulse on a float by no means annihilates all the motion of the water, and it bends round it and hits the one behind with its remaining force, there must be some advantage gained by employing a greater number of floats than this rule will permit. This is abundantly confirmed by the experiments of Smeaton and Bossut. The latter formed three or four suppositions of the number of floats, and calculated the impulse on each, according to the observations made in a course of experiments by the Academy of Sciences, and inserted by us in the article RESISTANCE OF FLUIDS; and when he summed them up, and compared the results with his experiments, he found the agreement very satisfactory. He deduces a general rule, that if the velocity of the wheel is one third of that of the stream, and if seventy-two degrees of the circumference are immersed in the stream, the wheel should have thirty-six floats. Each will dip one fifth of the radius. The velocity being still supposed the same, there should be more or fewer floats according as the arch is less or greater than seventy-two degrees.

Such is the theory, and such are the circumstances which it leaves undetermined. The accumulation of the water on a float-board, and the force with which it may still strike another, are too intricate to be assigned with any tolerable precision: for such reasons we must acknowledge that the theory of undershot wheels is still very imperfect, and that recourse must be had to experience for their improvement. We therefore strongly recommend the perusal of Mr Smeaton's experiments on undershot wheels, contained in the same dissertation with those which we have quoted on overshot wheels. We have only to observe, that to an ordinary reader the experiments will appear too much in favour of undershot wheels. His aim is partly to establish a theory, which will state the relation between their performance and the velocity of the stream, and partly to state the relation between the power expended and the work done. The velocity in his experiments is always considerably below that which a body would acquire by falling from the surface of the head of water; or it is the velocity acquired by a shorter fall. Therefore if we estimate the power expended by the quantity of water multiplied by this diminished fall, we shall make it too small, and the difference in some cases is very great; yet, even with these concessions, it appears that the utmost performance of an undershot wheel does not surpass the raising one third of the expended water to the place from which it came. It is therefore far inferior to an overshot wheel expending the same power; and M. Belidor has led engineers into very mistaken maxims of construction, by saying that overshot wheels should be given up, even in the case of great falls, and that we should always bring on the water from a sluice in the very bottom of the dam, and bring it to the wheel with as great a velocity as possible. Mr Smeaton also says, that the maximum takes place when the velocity of the wheel is two fifths of that of the stream, instead of two sixths according to the theory; and this agrees with the experiments of Bossut. But he measured the velocity by means of the quantity of water which ran past. This must give a velocity somewhat too small, as will appear by attending to Du Buat's observations on the superficial, the mean, and the bottom velocities.

The rest of his observations are most judicious, and well adapted to the instruction of practitioners. We have only to add to them the observations of De Parcieux and Bossut, who have evinced, by very good experiments, that there is a very sensible advantage gained by inclining the float-boards to the radius of the wheel about twenty degrees, so that the lowest float-board shall not be perpendicular, but have its point turned up the stream about twenty degrees. This inclination causes the water to heap up along the float-board, and act by its weight. The floats should therefore be made much broader than the vein of water interrupted by them is deep.

Some engineers, observing the great superiority of overshot wheels above undershot wheels driven by the same expense of power, have proposed to bring the water home to the bottom of the wheel on an even bottom, and to make the float-board no deeper than the aperture of the sluice, which would permit the water to run out. The wheel is to be fitted with a close sole and sides, exactly fitted to the end of this trough, so that if the wheel is at rest, the water may be dammed up by the sole and float-board. It will therefore press forward the float-board with the whole force of the head of water. But this cannot answer; for if we suppose no float-boards, the water will flow out at the bottom, propelled in the manner those persons suppose; and it will be supplied from behind, the water coming *slowly* from all parts of the trough to the hole below the wheel. But now add the floats, and suppose the wheel in motion with the velocity that is expected. The other floats must drag into motion all the water which lies between them, giving to the greatest part of it a motion vastly greater than it would have taken in consequence of the pressure of the water behind it; and the water out of the reach of the floats will remain still, which it would not have done independently of the float-boards above it, because it would have contributed to the expense of the hole. The motion therefore which the wheel will acquire by this construction must be so different from what is expected, that we can hardly say what it will be.

We are therefore persuaded that the best way of delivering the water on an undershot wheel in a close mill-course is, to let it slide down a very smooth channel, without touching the wheel till near the bottom, where the wheel should be exactly fitted to the course; or to make the floats exceedingly broader than the depth of the vein of water which glides down the course, and allow it to be partly intercepted by the first floats, and heap up along them, acting by its weight after its impulse has been expended. If the bottom of the course be an arch of a circle described with a radius much greater than that of the wheel, the water which slides down will be thus gradually intercepted by the floats.

Attempts have been made to construct water-wheels which receive the impulse obliquely, like the sails of a common wind-mill. This would, in many situations, be a very great acquisition. A very slow but deep river could in this manner be made to drive our mills; and although much power is lost by the obliquity of the impulse, the remainder may be very great. It is to be regretted that these attempts have not been more zealously prosecuted; for we have no doubt of their success in a very serviceable degree. Engineers have been deterred, because when such wheels are plunged in an open stream, their lateral motion is too much impeded by the motion of the stream. We have however seen one which was very powerful. It was a long cylindrical frame, having a plate standing out from it about a foot broad, and surrounding it with a very oblique spiral like a cork-screw. This was plunged about one fourth of its diameter (which was about twelve feet), having its axis in the direction of the stream. By the work which it was performing, it seemed more powerful than a common wheel which occupied the same *breadth* of the river. Its length was not less than twenty feet: it might have been twice as much, which would have doubled its power, without occupying more of the water-way. Perhaps such a spiral, continued to the very axis, and moving in a hollow canal wholly filled by the stream, might be a very advantageous way of employing a deep and slow stream.

But mills with oblique floats are most useful for employing small streams, which can be delivered from a spout with a great velocity. Bossut has considered these with due attention, and ascertained the best modes of construction. There are two which have nearly equal performances.

1. The vanes being placed like those of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to strike them, let the spout be so directed that the vein may strike them perpendicularly. By this measure it will be spread about on the vane in a thin sheet, and exert a pressure nearly equal to twice the weight of a column whose base is the orifice of the spout, and whose height is the fall producing the velocity. Mills of this kind are much in use in the south of Europe. The wheel is horizontal, and the vertical axis carries the mill-stone; so that the mill is of the utmost simplicity: and

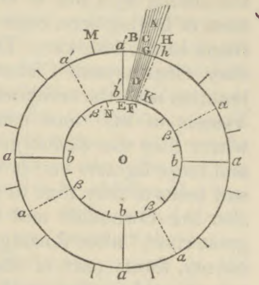
this is its chief recommendation, for its power is greatly inferior to that of a wheel constructed in the usual manner.

2. The vanes may be arranged round the rim of the wheel, not like the sails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes passing through the axis. They may either stand on a sole, like the oblique floats recommended by De Parcieux, as above mentioned; or they may stand on the side of the rim, not pointing to the axis, but aside from it. This disposition will admit the spout to be more conveniently disposed either for a horizontal or a vertical wheel.

We shall conclude this article by describing a contrivance of Mr Burns, the inventor of the double bucketed wheel for fixing the arms of a water-wheel. It is well known to mill-wrights that the method of fixing them by making them to pass through the axle, weakens it exceedingly, and by lodging water in the joint, soon causes it to rot and fail. They have therefore of late years put cast-iron flanches on the axis, to which each arm is bolted; or the flanches are so fashioned as to form boxes, serving as mortises to receive the ends of the arms. These answer the purpose completely, but are very expensive; and it is found that arms of fir bolted into flanches of iron are apt to work loose. Mr Burns has made wooden flanches of a very curious construction, which are equally firm, and cost much less than the iron ones.

This flanch consists of eight pieces, four of which compose the ring represented in fig. 15, meeting in the joints *ab*, *ab*, *ab*, *ab*, directed to the centre O. The other four are covered by these, and their joints are represented by the dotted lines $\alpha\beta$, $\alpha\beta$, $\alpha\beta$, $\alpha\beta$. These two rings break joints in such a manner that an arm MN is contained between the two nearest joints $a'b'$ of the one, and $\alpha'\beta'$ of the other. The tenon formed on one end of the arm A, &c., is of a particular shape: one side, GF, is directed to the centre O; the other side, BCDE, has a small shoulder BC; then a long side CD directed to the centre O; and then a third part DE parallel to GF, or rather diverging a little from it, so as to make up at E the thickness of the shoulder BC; that is, a line from B to E would be parallel to CD. This side of the tenon fits exactly to the corresponding side of the mortise; but the mortise is wider on the other side, leaving a space GFK*h* a little narrower at FK than at G*h*. These tenons and mortises are made extremely true to the square; the pieces are put round the axle, with a few blocks or wedges of soft wood put between them and the axle, leaving the space empty opposite to the place of each arm, and firmly bolted together by bolts between the arm-mortises. The arms are then put in, and each is pressed home to the side CDE, and a wedge HF of hard wood is then put into the empty part of the mortise and driven home. When it comes through the flanch and touches the axle, the part which has come through is cut off with a thin chisel, and the wedge is driven better home. The spaces under the ends of the arms are now filled with wedges, which are driven home from opposite sides, till the circle of the arms stands quite perpendicular on the axle, and all is fast. It needs no hoops to keep it together, for the wedging it up round the axle makes the two half rings draw close on the arms, and it cannot start at its joints till it crushes the arms. Hoops however can do no harm when all is once wedged up, but it would be improper to put them on before this be done.

Fig. 15.



(B. B. B.)

WATERFORD, a maritime county of the province of Munster, in Ireland, is bounded on the north by the counties of Tipperary and Kilkenny, on the east by that of Wexford, on the south by the Atlantic, and on the west by the county of Cork. It lies between 51° 55′ and 52° 20′ north latitude, and 6° 58′ and 8° 10′ west longitude; extending twenty-eight miles in its greatest length from north to south, and fifty-two in breadth from east to west, and comprehending an area of 736 square miles, or 471,281 acres, of which 353,247 are cultivated land, and 118,034 uncultivated mountain or bog. It ranks as the twenty-first county in superficial extent, and the twentieth in that of its cultivated land.

In the time of Ptolemy the geographer, it was inhabited by the tribe of the Brigantes, whose territory extended from Carnsore Point in Wexford, westward along the coast to the Blackwater. It was afterwards peopled by the Desii, who are supposed to have emigrated from a tribe of the same name in Meath; and having spread themselves also over the plain country of Tipperary, those settled in Waterford were distinguished by the name of South Desii, and the others by that of North Desii. Here the Danes established a permanent settlement in the ninth century, making the city of Waterford their chief seat of government; and though frequently involved in wars with the surrounding natives, they retained possession of the city and district until their subjugation by the English, who, in 1170, under Strongbow, stormed Waterford, took their chieftain or prince prisoner, and brought the whole of the Decies into the possession of the English. Shortly after Henry II. granted the greater part of the county to Robert le Poer, and the remainder, with that of Cork, then a petty kingdom, to Milo de Cogan, two of his followers. In 1210, King John erected the territory into a county, from which the city was excepted, being under a separate jurisdiction. In 1444 the county, together with the greater part of the rest of Munster, was granted to James earl of Desmond. A few years after, both county and city were granted to John Talbot, earl of Shrewsbury, who was then created earl of Waterford; but both lands and title were resumed by the king under the statute 28th Hen. VIII., which vested the lands of absentee proprietors in the crown. The county suffered severely in the reign of Elizabeth, through the rebellion of the earl of Desmond, and the Spanish invasion; and also in the wars of 1641, during the first years of which, its possession was the subject of continued sanguinary contention between the English and Irish forces, until it was ultimately reduced under the authority of the English parliament by Cromwell. During the war of the Revolution, it took part with King James, and was reduced by King William's forces under General Kirk, after the decisive battle of the Boyne.

The general character of the county is mountainous. The Knockmeledown ridge, the highest point of which is 2598 feet above the sea-level, ranges along its north-western boundary, forming the line of demarcation on the side of Tipperary. The Cummeragh and Monevolagh Mountains lie in a direction nearly north and south from the east of Clonmel to Dungarvan; their loftiest summit, Knockanafrian, is 2469 feet high. On several of the summits of these mountains are large piles of stones, apparently of artificial construction, but of unknown origin. To the south of Dungarvan are the Drum Mountains, much lower than the preceding, but rugged and difficult of passage. They form the division between two of the baronies. The south-eastern district is low, of alluvial formation, and forms a kind of peninsula, cut off from the remainder of the county by a line of marshy land, which has the appearance of having been once under water. There are no large rivers in the interior. The Suir forms its northern boundary, from beyond Clonmel, to the estuary formed by its junction with the combined waters of the Barrow and Nore. Vessels of 800 tons come up to the city of Waterford, where they can discharge their cargoes at the quay; barks and large lighters can proceed upwards to Carrick-on-Suir, and boats of fifty tons to Clonmel. The Blackwater, called also the Owenduff and Owenmore, "the black and the great river," after flowing through the western part of the county, forms part of the boundary on the side of Cork county, and discharges itself into Youghal harbour. It is navigable for vessels under 100 tons to its confluence with the Bride, a smaller stream which joins it from the west. The Brickey empties itself into Dungarvan harbour. The Neir, in the west of the county, is a small tributary of the Suir. There are no lakes, except a few of very small size in the Cummeragh Mountains, the largest, called Cummeloughs, are but six or eight acres in extent, the others, called Stilloughs, smaller. A tract at Ballyscanlan, in Middlethird barony, covered with water during winter, subsides into a small lake in the dry season. The county enjoys the benefit of an extensive line of sea-coast. Two miles east of the city is the Little Island, of triangular shape; after which the coast takes a southern direction, forming the western side of Waterford harbour, at the entrance of which is the pier harbour of Dunmore, with a lighthouse exhibiting a fixed light, red towards the sea and bright inland. The harbour, in which vessels of fifteen feet draught may lie afloat, covers a cove of six acres. West of Dunmore are the small islands of Fileskirt. Farther westward, between Brownstown and Newtownheads, is Tramore Bay, notorious for shipwrecks. A vessel caught in it finds it almost impossible to work out by plying to windward. The ground is so foul and rocky, that cables are frequently cut and ships lost. The northwest is the only part which affords a possibility of escape, the east being so shoal and rocky that vessels driven on that side are involved in terrible breakers at a considerable distance from shore. Proceeding westward are the small grassy rocks called the Islands of Jeane, and the inlets called Bonmahon, Clonea, and Rineshark. Dungarvan harbour affords shelter to vessels of ten feet water. Ardmore Bay and Whiting Bay are still farther west. Youghal harbour forms the western boundary of the county. Off the coast, and extending along that of the southern part of the adjoining county of Wexford, is the Nymph Bank, long looked upon as an inexhaustible source of supply of round fish, but, according to late reports, much less productive than had been represented; the fish not being abundant, and of a poorer description than those taken on other banks.

The eastern part of the county consists of clay-slate, interrupted by small patches of primitive limestone, susceptible of a high polish, and by conglomerate and basalt, which latter appears in a columnar form on the cliffs over the sea. A copper mine at Knockmahon has been worked for several years, with good profit, by the Mining Company of Ireland. The ore is sent in a crude state to Swansea to be smelted. The average annual produce is stated at 4500 tons, valued at L.40,000. Lead was formerly raised in large quantities in the same district. The veins in the hill of Cruach and on the shore at Kilmurrin are said to have given out a large quantity of silver. The western part of the county is old conglomerate, with red, purple, green, and gray clay-slate. It is bordered in many parts by a band of millstone grit and white sandstone, which also constitutes the fringe of a broad bed of carbonated or mountain limestone, that passes through a great part of the interior from east to west. Slates from the quarries south of Lismore are raised at an average of 2800 tons annually, value L.4200. Mineral veins are also found in this district. At Ardmore an iron mine was formerly wrought, from which steel of superior quality was said to have been fabricated. The sandstone in many places is wrought into millstones. Ochres, boles, and clays, fit for the manufacture of earthenware, are found in various places.

The population of the county, according to calculations made at different periods, was as follows:

Date.	Authority.	Number of Inhabitants.
1760	De Burgo	60,096
1792	Beaufort	75,000
1812	Parliamentary census	119,457
1821	Ditto	127,842
1831	Ditto	148,077

According to the last of these returns, there was one inhabitant to every $3\frac{2}{5}$th acres of the entire surface, and the same to every $2\frac{1}{3}$d acres of cultivated land. The population, according to the return of the Commissioners of Public Instruction in 1834, which, being stated in dioceses instead of counties, cannot be considered numerically accurate, gives a total population of 182,018; of which number the members of the established church were 8391, the Protestant dissenters 861, and the Roman Catholics 172,766. The proportion of Roman Catholics to Protestants, including Protestant dissenters, is as 1 to 0·05352, or as 1 to $\frac{1}{20}$th nearly; or the Protestants are to the Roman Catholics as 1 to 18·67. The number of children receiving instruction in public schools was as follows, according to the returns under the population act in 1821, those of the Commissioners of Education in 1824–6, of the Commissioners of Public Instruction in 1834, and of the Board of National Education in 1836–7–8–9.

Date.	Males.	Females.	Sex not ascertained.	Total.
1821	6088	2119	—	8,207
1824–6	9476	5524	182	15,121
1834	7200	4100	300	11,600
1836–7	3498	1397	—	4,895
1837–8	2901	1774	—	4,675
1838–9	3510	2644	—	6,154

According to the return of 1824–6, in which only the religious persuasion of the people is noticed, the numbers are, of the established church, 1373; dissenters, 100; Roman Catholics, 13,662; religious persuasion not ascertained, 46. Out of the total number of 284 schools, stated in the same return, 22, having 1363 pupils, were maintained wholly by grants of public money; 32, having 3548 pupils, by voluntary contribution; the remaining 230 schools, containing 10,271 pupils, were maintained wholly by the fees paid by the relatives of the children.

The county is divided into the eight baronies of Coshbride, Coshmore, Decies within Drum, Decies without Drum, Gualtier, Glenaheiry, Middlethird, and Upperthird, which are subdivided into seventy-four parishes, thirty-three in the diocese of Waterford, and forty-one in that of Lismore; the cathedrals of each of these being in the cities of the same name with the respective dioceses. It sent eight members to the Irish parliament, two for the county, and two each for the city of Waterford and the boroughs of Dungarvan, Lismore, and Tallow. By the arrangements at the time of the union, the number was reduced to four, two for the county, and one each for Waterford city and Dungarvan. The reform act for Ireland added one member to the city. The constituency of the county under the act of 1829, by which the forty-shilling freeholders were disfranchised, and at other periods since the passing of the reform act in 1832, was as follows:

1831	1422	1836	1478
1832	1452	1837	1478
1833	1448	1838	1478
1834	1481	1839	1200
1835	1492		

The number of electors is, according to the last of these returns, to that of the number of inhabitants, as 1 to 123, and to that of families of six individuals each, as 1 to 20. The county is included in the Leinster circuit. The assizes are held in the city of Waterford, where the county prison is fixed. General sessions of the peace are held four times in the year in that city; twice a year at Dungarvan, and twice at Lismore; in each of which towns there are a court-house and a bridewell. The local government is vested in a lieutenant, fourteen deputy-lieutenants, fifty-nine other unpaid magistrates, and a stipendiary magistrate. The constabulary force consists of a county inspector, five sub-inspectors, six head constables, and 150 constables and sub-constables. The county infirmary and the lunatic asylum for the county and city are in Waterford city, where also is a fever hospital; and there are others in Dungarvan, Lismore, and Tallow. There are twelve dispensaries in various towns. Waterford, Dungarvan, and Lismore have been fixed on as sites for the workhouses of poor-law unions.

Though the land is in general coarse, there is a considerable tract of rich soil, particularly in the south-eastern quarter; and the mountainous districts afford good pasturage for cattle. The estates are in general very large: that of the duke of Devonshire is the most extensive. Tillage has increased very rapidly within the present century. In 1779, not one thirtieth part was under the plough. At present, nearly two thirds are under tillage. The change has arisen in some degree from the custom of dividing farms. When the eldest daughter of a farmer married, the father divided the land with his son-in-law; the next daughter got half of his remaining share for her portion, the system of subdivision being continued as long as there were any daughters to be thus provided for. The sons were left to shift for themselves as best they could. But the attention latterly paid to introduce the most approved agricultural practices, has contributed in a much greater degree to this effect. The lands of resident gentry are now specimens worthy of imitation. The settlement of the religious fraternity of St Bernard la Trappe, near Cappoquin, the members of which devote much attention to the reclamation and improvement of a large mountainous tract granted to them for their residence, has still further stimulated the spirit of industrious exertion, and given it a judicious direction. Wheat is largely raised, clover very generally grown; but other kinds of green crops are not yet so general as in England. Lime for manure is abundant in the western parts, and large quantities of coralline sea-sand are carried into the interior for the same purpose. The fences are mostly banks of earth topped with furze in the flat country, and dry stone walls in the mountainous parts. The best breeds of cattle are to be seen on the pastures. Sheep are not a common stock; swine, raised chiefly for export, are very numerous, as are goats in the higher lands. Waterford is the principal dairy county in the island. The chief produce of these farms is butter, the export of which has increased considerably for several years. Very little cheese is made. The want of timber, both for ornamental and useful purposes, is much felt; but the deficiency is yearly diminished by the increased attention to plantations. There is but little bog. The extensive range of sea-coast, indented by numerous creeks and inlets, holds out great inducements for profitable employment in the fisheries. During the ten years' continuance of the system of bounties, and of grants and loans for the building and repairs of boats and the purchase of fishing gear, adopted by the Board of Fisheries instituted in 1819, the sea-fishery was carried on with much spirit, and caused a large circulation of money, particularly in Dungarvan, the centre of the system. Some working fishermen accumulated capital; some became boat-owners, and some boat-owners masters of trading vessels. But on the termination of the bounties and grants, the business declined rapidly. The boats fell into decay, and were laid up. Those fishermen who had no land, but depended wholly on the success of their occupation at sea, were reduced to poverty, and, in seasons when the fishery wholly failed, to a state of utter destitution. Yet the market is so far from being overstocked, that the quantity of fish taken on the coast never equals the demand in the local markets, Scotish and Newfoundland fish being sold in very large quantities. A company formed in Waterford between thirty and forty years ago, for supplying the English markets with round fish from the Nymph Bank by well-boats, failed, owing, it is alleged, to mismanagement. The following summary exhibits the number of vessels employed in the last year in which the bounty and loan system was in operation, and in that when a second board of commissioners repeated the inquiries as to the state of the Irish fisheries.

	Decked Vessels.		Half-decked.		Open Sail-boats.	Row-boats.	Number of Fishermen.
	Number.	Tonnage.	Number.	Tonnage.	Number.	Number.	
830	69	1239	64	960	40	270	1983
836	—	—	101	1668	52	266	2516

The coasts abound with shell-fish. Salmon, and other species of river-fish, are taken in large numbers in the Blackwater and Suir, and in the numerous smaller streams.

Carrick-on-Suir was once the centre of a very extensive woollen manufacture, which branched out into most parts of this county. It has been for many years almost extinct, the supply at present serving only for the domestic consumption of the peasantry. Linen is made in the farm-houses, but only for family use. A cotton factory has been established at Portlaw, to the west of Waterford city, which gives employment to a large number of workers. There are distilleries, breweries, and paper-mills. Flour is also extensively manufactured, and largely exported. Some glass is made at Waterford, and coarse earthenware in several places; but Waterford is not a manufacturing county. The inland trade chiefly centres in Waterford city, which is also a good emporium for the export of grain and salted provisions. Some business in both departments is also done at Dungarvan and Youghal. The exports and imports in 1838 were stated in a parliamentary return to be,—

	Exports. Tons.	Value. £.	Imports. Tons.	Value. £.
Waterford	118,000	2,060,000	130,000	1,572,000
Dungarvan	7,500	75,000	11,000	15,000
Total	125,500	2,135,000	141,000	1,587,000

An act has passed for a railroad from Waterford city, to proceed along the northern side of the Suir, by Carrick-on-Suir and Clonmel, to join the great southern line near Cahir. There are six banking establishments in the county; of which one is a branch of the Bank of Ireland, two of the Provincial Bank, and the other three of the National Bank. There are eight loan companies, established under a late act, in different places. The amount of the loans in the borrowers' hands at the close of 1839 was L.4011, and the number of borrowers during the year, 3482.

Among the mansions of the nobility and gentry of large estates, the most remarkable are Lismore Castle, the seat of the duke of Devonshire, and Curraghmore, that of the marquis of Waterford. The habitations, dress, and manners of the peasantry in the rural districts, resemble those similarly circumstanced in other parts of the province, being distinguished chiefly by the difference of their modes of life, as residing on the sea-coast, the rich pasture-lands, the mountain districts, or the vicinity of a populous town. The county contains numerous remains of ancient structures. A pillar-tower at Ardmore is in a state of high preservation. Near the same place is a large rath, and several others in various parts. The remains of small circular intrenchments, mostly at short distances from each other, can also be traced. Cromlechs are also numerous, and some very large. The names of upwards of twenty monastic establishments have been preserved, but the sites of few of them are now discernible. The same may be said of the numerous castles erected in many parts of this county, long the theatre of petty wars. Natural caves are to be seen, both on the coast and in the interior, as well as others which have every appearance of owing their origin to human ingenuity. There are several mineral springs, chiefly chalybeate.

The city of Waterford is situate on the northern verge of the county, and on the southern bank of the Suir, about twenty miles from the mouth of the harbour. It was founded by the Danes, according to some authorities, as early as the middle of the second century, but, as stated by others with more probability, in the ninth century. It continued in the possession of these settlers, wholly independent of the surrounding native princes, and generally at variance with them, till the arrival of the English under Strongbow, who took it by storm, and was in the act of consummating his victory by an indiscriminate massacre of the inhabitants, when he was prevented by the interference of his ally and protector Dermott M'Murrough, king of Leinster, whose daughter Eva he soon after married in the city. Henry II. afterwards landed here, and from that period it long continued to be one of the principal places of communication with England, and a considerable mart for foreign trade. King John, when earl of Morton, landed here in 1183. On his accession to the throne, he granted its first charter, and again visited the city the year after. In the next century it suffered twice by conflagrations, the latter time so severely, that it remained several years in a decayed state. In 1368, the citizens, under the command of the mayor, suffered a severe defeat from the Poers and O'Driscolls. At the close of the same century, Richard II. landed here on both the occasions on which he visited this part of his dominions. Money was coined here by the Danes, and a mint established by John; a privilege confirmed by Edward IV. when he abolished all the mints in Ireland except those of this city, Dublin, and Drogheda. Waterford signalized itself by its steady attachment to the royal interests during the attempts of Simnel and Warbeck, in the reign of Henry VII. The latter of these pretenders laid siege to it, but was forced to withdraw his forces, in commemoration of which the city obtained its motto, "Urbs intacta manet." At the close of the long-continued warfare which had devastated Ireland during the latter part of Elizabeth's reign, the citizens objected to having James proclaimed, and refused admission to Lord Mountjoy, then lord-deputy, and his forces, until compelled by his threats to submit. In the wars of 1641, they sided with the confederate Catholics, and after several vicissitudes of fortune, ultimately capitulated to the parliamentary army under Ireton. In the subsequent war in 1688, they took part with King James, who here embarked for France after his defeat at the Boyne; and the city shortly afterwards surrendered, upon terms, to King William's forces under General Kirk.

The walls of the Danish city enclosed a triangular area of about fifteen acres. The only remaining vestige of them is a round tower, built by one of the Danish sovereigns, and from him named Reginald's Tower, which has been rebuilt from its ruins, and is now occupied as a barrack. The county of the city extends along the river from Carrick-on-Suir to Passage, and on the north side beyond the river into Kilkenny county. This portion is connected with the main body by a wooden bridge. It comprehends an area of 9683 acres, including 822 on which the city stands, and contains twelve parishes, three of which are rural. The corporation consists of a mayor, who has a sword borne before him, two sheriffs, eighteen aldermen, and eighteen assistants, with a recorder and inferior civic officers. The city returns two members to the imperial parliament. The constituency, since the passing of the reform act, consists of the resident freemen, the L.10 freeholders, the L.20 and L.10 leaseholders for a term of years, and the 40 shilling freeholders during the continuance of the existing lives. The numbers registered have been,

In 1833	1241	In 1837	1473
... 1834	1241	... 1838	1473
... 1835	1241	... 1839	1220
... 1836	1473		

The municipal courts are, a court of record twice in the week; a civil bill court, for debts from forty shillings to ten pounds; a court of conscience, for debts under forty shillings; the mayor's court, for disputes as to servants' wages; and a court leet and court of admiralty, both now obsolete. The city business is transacted in the town-hall, an elegant modern building. Besides the county court-house and prison already noticed, there is a city gaol, and a penitentiary or house of correction. The ecclesiastical buildings are, the cathedral, founded in 1076, but since taken down and rebuilt; several parochial churches, Roman Catholic chapels, and dissenting meeting-houses. There are several endowed schools, the principal of which are the blue-coat schools for boys and girls. Among the charitable institutions are, the Widows' Houses; the Leper House, now a general infirmary; the Hospital of the Holy Ghost; the Fever Hospital, the first founded in Ireland; and the District Lunatic Asylum, confined to the county and city, and maintaining at present 101 patients, of whom eighteen are idiots, and eighty-three lunatics, of whom thirty-four are supposed to be curable. The literary and scientific institutions are, the Waterford Institution, with a library and museum; the Literary and Scientific Society, where lectures are delivered; an Agricultural, and a Horticultural Society. There are cattle-markets twice in the week, and chartered fairs three times in the year.

The quay, which extends along the bank of the river from one end of the town to the other, and from which most of the other streets branch out, is the most ornamented part of the city. The custom-house is in its centre. Waterford derives its wealth and importance from its commerce, which is now chiefly with Great Britain. So early as the commencement of last century, it adopted the liberal policy of admitting foreign traders to the freedom of the city, which induced several intelligent merchants from the continent to settle here. The exports are mostly cattle, sheep, pigs, grain, flour, and salted and dried provisions. Mercantile affairs are superintended by the Chamber of Commerce, incorporated in 1815, and by the Board of Harbour Commissioners, established by act of parliament in 1816 for the improvement of the port. Under their management a dock-yard has been constructed, capable of receiving vessels of very large dimensions, and the main passages of the river have been cleansed and deepened. The coequence has been a rapid and extensive increase of tra. Steamers of the first class have for several years pli regularly to Liverpool and Bristol.

he population of the county of the city amounted in 18 to 28,679, in 1831 to 28,821, and in 1834 to 29,352. Ofhe last-named number, 4427 were members of the estlished church, 429 Protestant dissenters, and 24,433 Ro an Catholics. The population of the other towns containg more than 2000 souls each, was, in 1831, Dungarva 6519; Tallow, 2998; Lismore, 2894; Carrickbeg (a subrb of Carrick-on-Suir), 2704; Cappoquin, 2289; and Trore, 2224. (C. P.)

ATERLAND, an island in the South Pacific Ocean, disvered by Le Maire and Schouten in 1616. Long. 149. 30 W. Lat. 14. 46. S.

ATERLAND, Daniel, D. D., a learned English divi who greatly distinguished himself in theological controersies, was born in 1683, at Wasely in Lincolnshire, of whh place his father was rector. He had his academical leaing at Magdalen College, Cambridge, where he drew up a ueful tract, which went through several editions, entitled Adce to a Young Student, with a Method of Study for th irst four years. In 1713 he became master of the colleg was soon after appointed chaplain to George I., and at e time of his death, in 1740, was canon of Windsor, ardeacon of Middlesex, and vicar of Twickenham. A colctive edition of his Works, with a review of his life and wrngs, was published by Bishop Van Mildert. Oxford, 18, 10 vols. 8vo. A general index, forming the eleventh volne, was added in 1828.

ATERLOO, a village of Belgium, ten miles south of Brsels, with about 1600 inhabitants. Its name has been rered famous by the battle which decided the fate of Naoleon. For an account of that battle, see the article W.

ATFORD, a market-town of the county of Hertford, in e hundred of Caisho, 17½ miles from London. It stas on the river Colne, a few miles from its source at Otrpool. It is well built and pleasantly situated, consisting principally of one street. There is a good market on Sarday, and two annual fairs are held. The chief trade is nning silk. The population amounted in 1821 to 47, and in 1831 to 5293; but this estimate includes the inbitants of three hamlets which form a portion of the pah, though not of the town.

ATLINGTON, an irregularly built market-town of th county of Oxford, in the hundred of Pirton, forty-three mis from London. It stands in a hilly district, called the Clern Hills, has an endowed school, and a market on Sarday, with two annual fairs. The population amounted 1821 to 1479, and in 1831 to 1833.

ATSON, Robert, LL. D., an elegant historian, was bo at St Andrews, about the year 1730. He was the so of an apothecary of that place, who was also a brewer. Hing gone through the usual course of languages and phsophy at the school and university of his native cit and also entered on the study of divinity, a desir of being acquainted with a larger circle of literati, an of improving himself in every branch of knowledge, caed him, first to the university of Glasgow, and afterwas to that of Edinburgh. The period of theological stues at the universities of Scotland is four years; but dug that period, young men of ingenious minds find suient leisure to carry on and advance the pursuits of geral knowledge. Mr Watson pursued his studies with arur. Few men ever studied more constantly. It was a re with him to study eight hours every day; and this ru he observed during the whole course of his life. An acaintance with the polite writers of England, after the unn of the two kingdoms, became general in Scotland; an in Watson's younger years, an emulation began to prevail of writing pure and elegant English. He applied himself with great industry to the principles of philosophical or universal grammar; and by a combination of these with the authority of the best English writers, formed a course of lectures on style or language. He proceeded to the study of rhetoric or eloquence, the principles of which he endeavoured to trace to the nature of the human mind. He delivered a course of lectures in Edinburgh on these subjects, and met with the countenance, approbation, and friendship of Lord Kames, Mr Hume, with other men of genius and learning.

At this time he had become a licentiate; and a vacancy having happened in one of the churches of St Andrews, he offered himself a candidate for that living, but was disappointed. Soon after he was appointed professor of logic; and he also obtained a patent from the crown, constituting him professor of rhetoric and belles lettres. The study of logic in St Andrews, as in most other places, was at this time confined to syllogisms, modes, and figures. Watson, whose mind had been opened by conversation, and by reading the writings of the wits that had begun to flourish in the Scottish capital, prepared and read to his students a course of metaphysics and logics on the most enlightened plan; in which he analysed the powers of the mind, and entered deeply into the nature of the different species of evidence of truth or knowledge. By his History of the Reign of Philip II. King of Spain, published at London in 1777, in 2 vols. 4to, Dr Watson attained in his lifetime a considerable degree of celebrity; and his History of the Reign of Philip III., published after his death, added to his fame. Of this last performance, however, he has only completed the first four books; the two last were written by Dr Thomson, at the desire of the guardians of his children. Lond. 1783, 4to.

Dr Watson was appointed principal of United College on the death of Dr Tulideph, but he only enjoyed this preferment for a few years. He married a lady of singular beauty and virtue, the daughter of Dr Shaw, professor of divinity in St Mary's College. By this lady he had five daughters, who survived him. He died in the year 1780.

Watson, *Richard*, Bishop of Landaff, celebrated as an able theologian, and as a professor of chemistry, was born in August 1737, at Heversham near Kendal, in Westmoreland. His ancestors had been farmers of their own estates for several generations; and his father had for forty years been master of the free school at Heversham, but was become infirm, and had resigned it a little before his birth. He was however educated at this school, and continued there till 1754, when he was sent as a sizer to Trinity College, Cambridge. He applied without intermission to his studies, and in 1757 he obtained a scholarship, with particular expressions of approbation from Dr Smith, who was then master. He had made it a constant practice in his mathematical pursuits, to think over the demonstration of every proposition that he studied, in his solitary walks; a habit which must certainly have been very conducive to the improvement of geometrical talent, though it could scarcely be adopted without great labour by those who follow the algebraical mode of analysis in all their investigations. After this period he passed many hours daily, for a considerable portion of his life, in the occupation of instructing others, without much enlarging the scale of his own information, though certainly not without adding to the solidity and precision of his knowledge of the most important elementary truths of science; and when he graduated in 1759, he was classed as the second wrangler, which he seems to have considered, not without reason, as the place of honour for the year, the senior wrangler, who was a Johnian, having, as it was generally believed, been unfairly preferred to him. In October 1760, he became a fellow of Trinity, and in November, assistant tutor of the college. Having taken

Watson. his degree of M. A. in 1762, he was soon afterwards made moderator of the scholastic exercises of the university, an arduous and honourable office, which he also filled in several subsequent years.

In 1764, he undertook a journey to Paris, though without being able to speak the language, in order to take charge of his young friend and pupil Mr Luther, who returned to England with him soon after. He was elected in the same year professor of chemistry, though he had never devoted any portion of his attention to that science; but he soon rendered himself sufficiently master of all that was then known of the science, to give a very popular course of lectures on the subject about a year after his election, with the assistance of an operator whom he had brought from Paris, and to become the author of a series of essays, which served for many years as the most agreeable introduction to the elementary doctrines and the ordinary processes of chemistry. He obtained from the government, by proper representations, a salary of L.100 a year for himself, and for all future professors. He also paid some attention to theoretical and practical anatomy, as having some relation to the science of chemistry. In 1767, he became one of the principal tutors of Trinity College; in 1769, he was elected a fellow of the Royal Society, and in October 1771, he unexpectedly obtained the important and lucrative appointment of regius professor of divinity, upon the premature death of Dr Rutherforth, and in that capacity he held the rectory of Somersham in Huntingdonshire. He had been little accustomed to the study of the divinity of the schools, or even of the fathers; but his eloquence and ingenuity supplied the want of theological learning, though he gave some offence to his more orthodox colleagues, by confining his arguments more strictly to the text of the scripture than they thought perfectly consistent with the duty of a champion of the church of England, which they considered to be the description of a professor of divinity in an English university. He attracted, however, as long as he officiated in person, audiences as numerous, to the exercises in the schools at which he presided, as had attended his chemical lectures.

He married, in December 1773, Miss Wilson of Dallam Tower in Westmoreland. Their union continued uninterrupted for more than forty years. In 1774 he obtained a prebend of Ely, in exchange for a rectory in Wales, which the duke of Grafton had procured for him; and he became archdeacon of Ely in January 1780: in the same year Bishop Keene presented him with the rectory of Northwold in Norfolk; and in 1782, his pupil, the duke of Rutland, gave him the rectory of Knaptoft in Leicestershire: the same interest obtained him also from Lord Shelburne the bishopric of Landaff. Here his episcopal preferment rested. He generally joined the politics of the opposition, and especially on the question of the unlimited regency; but he was too independent in his sentiments to become a very useful member of any administration; and he retired, before the end of the year 1789, without books, and with somewhat more of disgust than he ought in justice to have felt, to an estate which he had bought at Calgarth, on the banks of Winandermere, and occupied himself entirely, besides the education of his family, in agricultural improvements, especially in planting, for which he received a medal from the Society of Arts in 1789. His pupil, Mr Luther of Ongar in Essex, had died in 1786, and left him an estate, which he afterwards sold for something more than L.20,000.

He considered as one of the best practical results of his chemical studies, the suggestion which he made to the duke of Richmond, then master of the ordnance, respecting the preparation of charcoal for gunpowder, by burning the wood in close vessels, which, it seems, very materially improved the quality of the powder.

He had the liberality to confer, in 1804, a small living, as a reward for literary merit only, on Mr Davies, the author of the Celtic Researches. The next year, he applied with success to the duke of York for the promotion of his son, who had then the rank of a major; and his royal highness speedily complied with his solicitation, as a personal favour only, without waiting for any ministerial influence.

His health had been seriously impaired by an illness which attacked him in 1781, and which his friends attributed, though perhaps without sufficient reason, to excessive study. In October 1809, he had a slight paralytic affection, and another in 1811; but it was in 1813 that his last illness might be said to begin, and he sunk gradually till the 4th of July 1816. The elder of his two sons was in the army, the younger in the church: he left also several daughters. His writings are as miscellaneous as they are numerous, but none of them are bulky.

1. Institutionum Chemicarum pars Metallurgica. Cambr. 1768, 8vo. Repr. Ess. vol. v.

2. Experiments and Observations on the Solution of Salts. Phil. Trans. 1770, p. 325, Ess. v. Especially on the specific gravities of salts and their solutions. 3. Remarks on the Effects of Cold in February 1771. Phil. Trans. 1771, p. 213, Ess. v. With some experiments on congelation. 4. Experiment with a Thermometer having its bulb blackened. Phil. Trans. 1773, p. 40, Ess. v. Raised 10°. 5. Chemical Experiments and Observations on Lead Ore. Phil. Trans. 1778, p. 863, Ess. v. 6. Observations on the Sulphur Wells at Harrowgate. Phil. Trans. 1786, p. 171, Ess. v.

7. An Essay on the Subjects of Chemistry, and their General Division.

8. Assize Sermon, preached at Cambridge. 1769, 4to.

9. Letters to the Members of the House of Commons, by a Christian Whig, 1772.

10. 11. Two Sermons. Cambr. 1776, 4to. On the Revolution, and on the King's Accession.

12. A brief State of the Principles of Church Authority, 1773. Reprinted in 1813 as a charge.

13. A Fast Sermon, Feb. 1780.

14. A Sermon addressed to the Clergy of Ely, 1780. Recommending oriental literature.

15. An Apology for Christianity, in a series of Letters addressed to Edward Gibbon, Esq. Lond. 1776, 12mo. Often reprinted, and considered as very satisfactory, though the author confesses, with more of the courtier than of the orthodox divine, in a letter to Mr Gibbon, that the essay "derives its chief merit from the elegance and importance of the work it attempts to oppose."

16. Chemical Essays. Lond. 1781–7, 5 vols. 12mo. Addressed to his pupil the duke of Rutland. The work was intended for general information, and became extremely popular as a first introduction. The first volume relates to salts, sulphurs, vitriols, and gunpowder; the second to common salt, distillation, lime, clay, and pit-coal; the third to bitumens, charcoal, evaporation, lead, and lead ores; and the fourth to zinc, gum, metal, tin, copper, iron, and stones; the fifth is a republication of the author's earlier chemical tracts. After the completion of these volumes, he had the resolution to burn all his chemical papers.

17. A Letter to Archbishop Cornwallis on the Church Revenues, 1782. A plan for equalizing the bishoprics.

18. A Sermon preached the 30th Jan. before the Lords. 1784, 4to.

19. Visitation Articles, for the Diocese of Landaff.

20. Theological Tracts. Lond. 1785, 6 vols. 8vo. Collected from various authors, not excluding many works of dissenters from the church.

21. A Sermon on the Wisdom and Goodness of God, in having made Rich and Poor, 1785, 1793. Adapted to allay the discontents which were then prevalent among the lower classes.

22. Sermons and Tracts. Lond. 1788, 8vo. Chiefly republications.

23. An Address to Young Persons after Confirmation. 1789, 12mo.

24. Considerations on the Expediency of Revising the Liturgy. 1790, 8vo. Anonymous.

25. A Sermon preached for the Westminster Dispensary in 1785, with an Appendix. 1792.

26. A Charge to the Clergy of his Diocese. 1792, 4to.

27. Two Sermons and a Charge. 1795, 4to. The first sermon is entitled Atheism refuted; the second, The Christian Religion no Imposture.

28. An Apology for the Bible, in a series of Letters addressed to Thomas Paine. Lond. 1796, 12mo. An able and judicious answer to the contemptible work of a mischievous incendiary: it seems to have been singularly successful in producing clear and rapid conviction. Thanks were returned to the author from Ireland and from America, and he gained L.1000 by the sale of the book, besides allowing it to be often reprinted gratuitously.

29. An Address to the People of Great Britain. 1798, 8vo. Enforcing the necessity of submission to the exigencies of the times. It went through fourteen editions, besides several piracies; and it was reprinted in Ireland by order of Lord Camden, then Lord Lieutenant. Mr Wakefield answered it somewhat intemperately, and the bishop attempted ineffectually, out of respect for his classical acquirements, to lighten the punishment which was allotted to him.

30. Charge to the Clergy of Landaff. 31. Second Charge, 180. On similar subjects.

32. A Charge relating to Ecclesiastical Reform, 1802.

33. A Sermon preached at the London Hospital, 1802. Against the principles of Paine.

34. Thoughts on the intended Invasion, 8vo.

35. Substance of a Speech intended to have been delivered, 180. In favour of Catholic Emancipation.

36. Sermon preached before the Society for the Suppression of Vice, 1804.

37. A Charge to the Clergy, 1805. 38. Another Charge, on the Catholic Question, 1808.

39. Two Apologies, two Sermons, and a Charge. 1806, 8vo. Reprinted.

40. A second Defence of Revealed Religion, 1807. In two sermons, preached in the Chapel Royal.

41. A Paper on Planting and on Waste Land. Communications to the Board of Agriculture, vol. vii. 1808, 4to. 42. He had also written some Preliminary Observations in the Agricultural Report of Westmoreland.

43. Miscellaneous Tracts. Lond. 1815, 2 vols. 8vo. Religious, political, and agricultural. "His discourse on the first and second Adam, and the nature of death as affected by each, is almost unequalled in originality of thought and vigour of expression." Quarterly Review.

(44). It has been said that he published some papers in the Manchester Memoirs; but they do not appear in the indices.

45. Anecdotes of the Life of Richard Watson, Bishop of Landaff, written by himself at different times, and revised in 1814. Published by his son Richard Watson, LL. B. Prebendary of Landaff and Wells. Lond. 1817, 4to. Lond. 1818, 2 vols. 8vo. Quarterly Review, xviii. p. 229. Treated with great ability, but with too much severity. His chief mistake indeed seems to have been that he expected his literary merits alone to secure him political advancement; further than this, there is nothing disgusting to a candid reader, in the sincerity with which he displays the consciousness of his own merits. The praises of the reviewer himself are at least as energetic as those of the friends whose language he has occasionally copied; his censures are not less impressive; but for an author's censure of himself, it would be idle to look in a work of autobiography.

Though somewhat reserved, Dr Watson is said to have been remarkable for the simplicity of his manners and the equality of his temper. With respect to his conduct in the school of divinity, the reviewer confesses that "he ascended the chair with many eminent qualifications for his difficult and distinguished functions. The exercise of four years, as moderator of the philosophical schools, had rendered his faculty of speaking Latin perfectly easy; by great assiduity, the vices of his early education had been so far corrected that a false quantity was never heard to escape him; all the tricks and shifts of school logic were familiar to his mind, in addition to which, his acuteness and ingenuity were admirable. His majestic and commanding figure, his terrific countenance, his deep sonorous voice, the uninterrupted tenor of his sentences, which, though far from classical, were never either barbarous or solecistic, and, above all, the boldness and originality of his sentiments, seldom left the under graduates' places unoccupied in the theological school. It was sport to see how the grave professor would glide over the surface of the subject with every appearance of profundity, or when pinned, as his opponent hoped, into a corner, would wind himself out with all the lubricity of an eel. Still he had a large mind; he endured, he encouraged, *he delighted in the opposition of able men; he never flinched from the strokes of those who had more information than himself*, secure in the consciousness of his own ability to encounter learning by invention. The same tolerance of contradiction, the same dexterity in parrying attacks, he brought with him into private conversation, which rendered him, when the poison of politics did not operate on his constitution, a most agreeable and amusing debater. In these happier hours, and they were not few, he would even smile at the pomp and magnificence of his own manner, and relax into all the *playfulness* and pleasantry which are almost inseparable from *real genius*."

Watt.

Our critic appears, however, to have exceeded the limits of candour and of charity, when he asserts that "he was governed through life by the two leading principles of interest and ambition, both of which were thwarted in his political conduct, by a temper so wayward, and a presumption so overweening, that the disappointment produced by their collision embittered his mind, and exasperated his latter days to a very high degree of malignity. Accomplished as he was in academical learning, he had no ingenuous or disinterested love of knowledge: he read only that he might teach, and he taught only that he might rise."

"When he felt himself neglected, he avowedly and professedly abandoned all study, because, says he, 'eagerness in the pursuit of knowledge was a part of my temper till,' and only till, 'the acquisition of knowledge was attended with nothing but the neglect of the king and his ministers.' Disgusted, therefore, and disappointed, as much as broken in constitution, he withdrew into the wilds of Westmoreland without a library, and to this privation he voluntarily submitted almost thirty years. From taste he derived neither amusement nor occupation, for of taste he never had a tincture; placed amidst the most delicious scenes of England, he thought of nothing but turning his own portion of them to emolument!" Thus "this violent declaimer against sinecures and non-residence was the first who converted the regius professorship of divinity into a sinecure: this enemy of pluralities held at least *fourteen* places of preferment; this man of moderation in his wishes, and calm contentment, under the shade of retirement, spent the last twenty-nine years of his life in 'execrating' [complaining of] those who, for his factious obstinacy, had left him to that retirement, while he was occupied in nursing up a fortune, till, according to his own boast, with the poorest bishopric in the kingdom, he became the richest bishop upon the bench."

With respect to the merits of the question between him and the administration of his early friend Mr Pitt, there will probably be as many different opinions as there are readers of different political parties; but he had surely no right to expect that a ministry determined to support every minute article of the established constitution of the country, both in church and in state, should voluntarily add to the power and authority of a person who had repeatedly declared himself rather hostile than indifferent to many points which they thought essential to both; or even of one who felt so decided a conviction of the importance of every single opinion which he had himself adopted, as to refuse his concurrence in such measures of legislation as they might deem of vital importance to the good of the country, and such as had been sanctioned by the concurrent determination of the majority of a cabinet taking on themselves the whole responsibility of their proceedings. He must have been aware that a house divided against itself cannot stand, and that the members of every administration, in a country not despotic, must consent to give up something to each other's feelings, and to make a small sacrifice of private conviction for the great objects of public energy and unanimity. (L. L.)
